This point, however, concerns only the history of chemistry and is entirely unconnected with the main contents of the book, which is outstanding in its reliability. It is easy to predict that the book will become an indispensable standard work in all laboratories interested in radiochemical work.

# ORTHOPTEROID INSECTS OF FRANCE

Faune de France

56: Orthoptéroïdes. Par Prof. Lucien Chopard. (Fédération Française des Sociétés de Sciences naturelles: Office central de Faunistique.) Pp. 359. (Paris: Paul Lechevalier, 1951.) n.p.

THIS work by Prof. L. Chopard is more than a mere revision of the third volume ("Orthoptères et Dermaptères" by the same author, published 1922) of this well-known series: it has been expanded to include more detailed information and covers a wider field. Under the heading "Orthoptéroïdes", Prof. Chopard includes Orthoptera (s. str.), Dictyoptera, Isoptera, Cheleutoptera, Dermaptera, Embioptera and Plecoptera. The last of these groups (all of which the author, in accordance with modern views, regards as orders) has been treated separately by R. Despax in Vol. 55 of the series. The present volume is a guide to the identification of the French representatives of the remaining orders, and includes all information, both systematic and biological, which is likely to be useful for this purpose.

The work is arranged on the same plan as the other "Faune de France" volumes, with concise determination keys leading to brief descriptions. An importan improvement on the earlier edition is the inclusion o numerous drawings of whole insects (about one pe genus); among these are a number of figures o immature stages. Most of the remaining drawings serve to illustrate many of the finer distinctions used in the determination keys. They are reproduced from Vol. 8 of the series and are rather less accurate than those drawn specially for the present volume Altogether there are more than five hundred figures

The text is on the whole up to the usual high standard of this well-known authority; but it i difficult to accept some of the extreme measures taken in the classification of some of the groups For example, no fewer than sixteen Saltatorian groups generally regarded as subfamilies have been given family status, thus doubling the number o families ascribed to the Saltatoria by other recent workers. Although the formation of new families will be inevitable as the groups become better known, it would perhaps be wiser to adopt a rather more cautious attitude until greater attention has been given to studies on their comparative morphology and anatomy.

The biological notes given with the more common species are largely new and have very much increased the value of the book. In particular, the descriptions of the 'songs' of many of the species will be found very useful in confirming their identity. Ample references are given to the work of other authors on the biology of a number of the species.

It is clear that in recent years much progress has been made in the study of European Orthoptera. Since the earlier volume of 1922 there have been some twenty additions to the French list, and some of these have been newly described species. There have been considerable advances in the study o their biology and distribution, and in many cases the time is ripe for the application of the polytypic species concept. In presenting with the utmost clarity much of this new and varied information in a single volume, Prof. Chopard has met a real need by workers on the European fauna, and his book is likely to stimulate further interest in a group o insects which has hitherto been denied its fair share of attention.

# PREVENTION OF TUBERCULOSIS

Causes and Prevention of Tuberculosis

By Dr. Brice R. Clarke; with a Chapter on Mass Miniature Radiography, by Joseph Ritchie. Pp viii+288. (Edinburgh and London: E. and S Livingstone, Ltd., 1952.) 32*s*. 6*d*. net.

DURING the past quarter of a century, remarkable changes have occurred in the general outlook on nearly every aspect of the tuberculosis problem. Twenty-five years ago views on the pathogenesis o pulmonary tuberculosis were dominated by the theories of European pathologists. Ranke's three stages of the tuberculous infection, comparable with the three stages of syphilis, were commonly accepted at least as a useful way of thinking. Childhood infection was, in most countries, almost universal and was accepted by many as inevitable. In these circumstances, environmental and nutritional factors assumed an over-riding importance in the development of tuberculosis; and the most profitable method of preventing the disease seemed to be the encouragement of the general level of resistance to infection among the population. The prevention of massive infection was acknowledged to be important, but, in general, measures directed towards improved social and economic conditions seemed likely to be more immediately rewarding in their results than any possible attempt at the elimination of infection. The clinical application of vaccination by BCG was only just starting to be investigated on a considerable scale. In treatment of individual cases of the disease, rest and general hygienic measures were the only generally applicable methods. These were supplemented in suitable cases of pulmonary disease by various forms of medical and surgical collapse treatment, and in other forms of disease by surgical removal of diseased organs or operations designed to immobilize affected structures.

To-day in many countries a steadily diminishing incidence of childhood infection has led to more frequent primary infections of adolescents and young adults. The immediate effects of such infections are, on a statistical scale, different from those which follow childhood infection, progressive disease of the lungs following as an immediate sequel very much more frequently. Consequently, again on a statistical scale, the pathogenesis of pulmonary tuberculosis in the young adult has changed. In prevention, it follows that methods aimed at the avoidance of infection are more immediately rewarding than in the past, and the dangers to the adolescent and young adult of contact with open disease are more obvious. In treatment, the development of effective antibacterial drugs has revolutionized the position and, hand in hand with technical advances in surgery, has made possible forms of treatment which in combination may be so effective that for some patients they might almost warrant the description 'curative', a term which, in the past, no one has been bold enough to use in connexion with this disease. It is relevant to remark, however, that these recent developments in treatment have had a paradoxical effect on the demand for hospital accommodation and trained staff. Whereas the introduction of the sulphonamide drugs and of penicillin has resulted in a much smaller demand for hospital beds for the treatment of acute infections such as pneumonia, the treatment of tuberculosis by modern methods remains a lengthy affair, needing the co-operation of larger numbers of highly trained medical and ancillary workers than were necessary for the simpler methods of treatment available in the past. The problems of minimizing the economic effects of this long-continued disease upon the patient and his family, and of his rehabilitation to as normal a life as is possible for him at the end of his treatment, remain unchanged.

Dr. Brice Clarke's book discusses these problems, especially as they are related to the design and administration of tuberculosis services. It attempts to cover the vast field in a way that will be helpful to those working in these services, including in short compass not only the epidemiological aspects which are dealt with by McDougall's "Tuberculosis, a Global Study", but also, though less completely, the field of pathogenesis covered by A. R. Rich's monograph. Some aspects are of necessity dealt with rather briefly, and, in particular, the section dealing with bacteriology is so sketchy that it is difficult to decide for whom it is intended; but adequate bibliographies at the end of each chapter minimize such deficiencies. There are some *ex cathedra* statements with which not everyone will agree. Many of the tables and graphs are not provided with legends adequate to make them self-explanatory, and in any future edition this defect could well be remedied. On the whole, this is an adequate and useful summary of much work in the several fields of study relevant to the problems of those engaged in tuberculosis and public health services.

J. G. SCADDING

## THE EXTRA PHARMACOPŒIA (MARTINDALE)

**The Extra Pharmacopœia (Martindale), incorporating Squire's Companion**

Twenty-third edition. Vol. 1. Pp. xxii+1352. (London: Pharmaceutical Press, 1952.) 55*s*.

THE "Extra Pharmacopœia (Martindale)" has for long been the best book of reference for those who require quick access to the essential facts about medicines. The first edition appeared in 1883 and was followed by twenty-one more editions during the next sixty years. Publication was interrupted by the Second World War, and the world has had to wait eleven years for the twenty-third edition. Vol. 1, which has now appeared, is complete in itself and gives an account of practically all the drugs available in Great Britain and many foreign drugs as well. It contains more than a million words and looks like its immediate predecessor; but it is slightly larger in all dimensions and weighs about 40 per cent more. It incorporates an old rival in the form of "Squire's Companion to the British Pharmacopœia". This new edition includes four thousand abstracts, nearly three-quarters of which are from the past ten years, and a therapeutic index giving references to the medicines used in about seven hundred and fifty forms of illness.

Never has therapeutics advanced so rapidly as during the past ten years, and the editors are to be warmly congratulated on the way they have brought this book up to date. The official name of each drug is followed by its chemical name, molecular weight and trade names. Physical properties, such as solubility and stability, are briefly summarized. The dose is given and there are sections on toxic effects, antidotes, contra-indications and uses. The numerous abstracts give a clear idea of the value of the evidence about the effects of the different drugs in practical medicine. There are, for example, about forty abstracts on methonium compounds which give a clear picture of the rather uncertain state of our knowledge about them. Up-to-date information of this kind is given about all the latest drugs, the names of which are too numerous to mention. It has not been possible to give a list in the preface of all the new substances included, but a select list of about a hundred and fifty of them looks most impressive. Special sections are devoted to antibiotics (ninety-nine pages), immunological products (fifty pages), blood transfusion (thirty-one pages), ligatures and legislation.

This great work has been produced under the editorship of T. O. Denston, followed by K. R. Capper, with half a dozen assistants and a few expert advisers—S. L. Ward has been associated with this book since 1923. It is wonderful that so much has been done so well by so few.

J. H. GADDUM

# INTERNATIONAL SCIENTIFIC RADIO UNION

## MEETING IN SYDNEY

THE tenth general assembly of the International Scientific Radio Union (U.R.S.I.) was held in Sydney during August 11–21, 1952, followed by a visit, reception by the Commonwealth of Australia Government, and closing ceremonies at Canberra during August 22–23. This was followed by a two-day meeting of the Mixed Commission on the Ionosphere, also in Canberra, at which matters of common interest to the Union and the corresponding International Astronomical and Geophysical Unions were discussed. The proceedings of this Mixed Commission will be reported separately. Furthermore, advantage was taken of the presence of a number of British radio scientists to hold a meeting in Sydney of the Commonwealth Specialist Conference on Radio Research.

The assembly of the International Scientific Radio Union was attended by some seventy delegates representing fourteen countries, and by a large number of Australian scientific workers and engineers who, as observers, were interested in being present at the first meeting of an international scientific union to be held in Australia. The general organization of the work of the Union under seven Commissions, and the constitution of the British delegation have been given previously[1]. This article presents a general description of the Sydney meeting and a summary of the proceedings of the various Commissions.

### Measurements and Standards

The president of Commission 1 of the Union, Dr. J. H. Dellinger (United States), made an introductory statement on the progress of international work in the field of standards and measurements, and this was followed by two sessions of the Commission: the first on frequency and impedance measurement, under the chairmanship of Prof. M. Boella (Italy); and the second on power and special receiver measurements, under Dr. R. L. Smith-Rose (Great Britain). Twenty-eight papers, of which eleven were reports from national committees, were available and were considered according to the subject-matters of these sessions. Of great interest was a paper by C. J. Grebenkemper and J. P. Hagen (United States) which described the results of measurements on resonant cavities at very low temperatures, 1–3° K., in an investigation of superconductivity in metals at microwave frequencies. For a tin-plated resonator, the $Q$-value increased from $5 \times 10^4$ to more than $10^8$ as the temperature was reduced to the values mentioned. A discussion took place on the use of this technique for studying skin-effect in different metals, and on the influence of surface finish on the results.

Several papers dealt with various aspects of measuring power at ultra-high frequencies. These included a description by A. L. Cullen (Great Britain) of the radiation pressure method of measuring 10–60 W. at wave-lengths of 3 and 9 cm., and an account of a micro-calorimeter by A. C. Macpherson (United States) for the absolute measurement of a power of 1–15 mW. at a wave-length of 9 cm. A novel method of calibrating field-strength measuring equipment was described by H. E. Dinger and W. E. Garner (United States), in which the calibrating voltage from a signal generator is applied across the gap in the shield surrounding the loop antenna.

At the close of its work, Commission 1 confirmed its previous resolutions concerning the study of reception of standard-frequency transmissions and time signals, and the international comparison of methods of measuring power at radio frequencies. Also, mainly as a result of a paper by Dr. L. Essen (Great Britain), the following resolution was put forward and adopted by the general assembly of the Union: "As a result of investigations made in recent years by several different methods, it is recommended that the following value of the velocity of electromagnetic waves in vacuum be adopted for all scientific work: 299,792 ± 2 km./sec.".

### Troposphere and Wave Propagation

Under the presidency of Dr. C. R. Burrows, Commission 2 held four meetings at which some fifty papers and reports were discussed, dealing principally with the subjects of very-short-wave propagation both over optical paths and to distances beyond the horizon, and with the influence of meteorological conditions on this propagation. Particular note was taken of the requests made at the Geneva meeting (1951) of the International Radio Consultative Committee (C.C.I.R.) for co-operation in the study of tropospheric wave propagation in view of the importance of short radio waves (all wave-lengths less than 10 m.) in the development of broadcasting, television and communications generally. Results of the observation of fading on centimetre wave-lengths made in New Zealand, Sweden and the United States for distances up to about 100 km. were described and discussed, and it was generally agreed that it is difficult in many cases to explain the depth of fading in terms of the variations of the refractive index modulus over the whole path. Dr. J. B. Smyth (United States) emphasized the need for obtaining and studying micro-meteorological data, and claimed that in this way the main characteristics of radio-wave propagation over distances up to more than 100 km. could be predicted with a considerable measure of agreement with the experimental results.

Among the resolutions adopted by this Commission were recommendations that the scattering of radio waves by fluctuations in the lower atmosphere should be studied in different countries, with particular reference to the dependence of this scattering on latitude, climate and terrain. The statistical characteristics of fluctuations in atmospheric refractive index should also be explored, making use of recent developments in micro-meteorological measuring technique. In addition, it was recommended that at all frequencies above 30 Mc./s. research should be directed towards establishing a better understanding of the correlation between readily available synoptic meteorological data and radio propagation characteristics. While the Union takes all possible steps to ensure that national meteorological authorities are aware of the need of radio scientists for aerological observations, it has specially asked the Joint Commission of the International Geophysical Year (1957–58) to take into consideration the needs of radio meteorology when planning its programme of meteorological measurements.

## Ionosphere and Wave Propagation

Sir Edward Appleton presided over the sessions of Commission 3, which had about one hundred documents before it relating to various aspects of research on the ionosphere and the propagation of waves over a wide range of frequencies. A discussion on "Movements in the Ionosphere" was opened by Dr. G. H. Munro (Australia), followed by Dr. W. J. G. Beynon and Profs. L. G. H. Huxley and L. Manning among other speakers. It was clear that there is considerable interest in the study by radio methods of regular and irregular movements in the ionosphere. Knowledge of these movements is rapidly accumulating and is of great interest from the point of view of upper-atmospheric meteorology.

One of the most interesting topics discussed concerned the effective conductivity of the atmosphere. At the second session of the Commission, papers were presented by Drs. W. G. Baker and D. F. Martyn (Australia)[2], with additional contributions by Prof. T. G. Cowling and K. Hirono, all of whom showed how, in spite of the presence of the earth's magnetic field, the conductivity could reach a magnitude of the order required in the theory of geomagnetism. This was followed by a discussion on "Ionospheric Storm Phenomena", opened by Dr. Martyn[3] and continued by Sir Edward Appleton and others. This subject is of considerable interest not only to scientific workers interested in relating ionospheric disturbances to other geophysical phenomena, but also to the radio engineers who are seeking reliable forecasts on the progress of ionospheric storms around the world, so that they may anticipate the considerable interruption of communication circuits which accompanies such storms.

Considerable interest was also aroused in a discussion, opened by J. C. W. Scott (Canada), on the propagation of very-high-frequency radio waves over distances of the order of 1,000–1,500 km., by way of scattered reflexions in the ionosphere. The relationship between scattering at normal and at grazing incidence was emphasized, and it was pointed out that, for frequencies exceeding the normal maximum usable frequency, the reflexion coefficient may be determined by a very thin layer rather than by a general increase in ionization. Reference was made to the observations taken in Great Britain, Australia, New Zealand and the United States on the scattering of very-high-frequency radio waves due to the incidence of meteors in the ionosphere. It appears that meteor showers add to a fairly constant level of meteoric activity which is always present at a height of about 110 km., the diurnal variation resulting from such showers being much more marked in the winter than in the summer months, at any rate in the southern hemisphere.

A discussion on wave-interaction was opened by Mr. R. A. Smith (Australia), deputizing for Prof. V. A. Bailey, who was prevented by illness from being present, and was continued by Dr. M. Cutolo (Italy), Prof. L. G. H. Huxley (Australia) and Mr. J. A. Ratcliffe (Great Britain). This was followed by a presentation by Dr. R. A. Helliwell (United States) of some papers dealing with an investigation of the characteristics of the ionosphere at a frequency of 150 kc./s. and the corresponding propagation of low-frequency waves. Some of this work was concerned with a study of turbulence in the lower region of the ionosphere and with stratification in the sporadic-*E* layer.

The following resolutions were formulated as a result of the deliberations of Commission 3: a world-wide study of movements in the ionosphere should be made; attention should be given to the method of measuring ionospheric absorption using galactic noise signals; attention should be given to the study of aurorae by the radio-echo method and to the effects of aurorae on galactic noise radiations; there should be an extended study of the development and morphology of ionospheric storms; and experiments should be made in all parts of the world on the propagation of very-high-frequency waves by ionospheric scattering.

## International Geophysical Year

In 1950 the Mixed Commission on the Ionosphere put forward a proposal for a Third International Polar Year to be held during 1957–58, the previous Polar Years having been held during 1882 and 1932–33. Subsequent discussion had made it clear that the former emphasis on the polar nature of the project would need modification, since observations in tropical latitudes are now also of great interest. Accordingly, it has been agreed to change the title to "International Geophysical Year 1957–58"; and during the Sydney meeting the International Scientific Union established its own committee, under the chairmanship of Sir Edward Appleton, to advise on all aspects of radio work during this year. The Union also suggested that each country should establish a Geophysical Year Committee.

In connexion with proposals made for a new world determination of longitude during the Geophysical Year, a sub-commission of the Union, under the chairmanship of Prof. M. Boella, was appointed to study the propagation time of radio signals over long distances, and to collaborate with the International Union of Geodesy and Geophysics and with the International Astronomical Union.

## Terrestrial Atmospherics

In the absence of Prof. H. Norinder (Sweden) the meetings of Commission 4 were presided over by Mr. J. A. Ratcliffe (Great Britain) and were chiefly devoted to discussions on the wave-forms and mean level of atmospherics, and on the characteristics from which the interference to different types of communication system can be determined. On the first subject, Dr. R. Rivault (France) pointed out that the wave-form of atmospherics received over the same distances depend to some extent upon the geographical location of the lightning strokes from which they arise. Mr. Ratcliffe gave an account of recent work on 'whistling atmospherics' and of a tentative theoretical explanation of these. Dr. R. A. Helliwell (United States) said he had recorded such 'whistlers' simultaneously at two places about 1,500 km. apart.

On the measurement of the general level of atmospheric noise, the meeting agreed with the recommendation by the International Radio Consultative Committee to continue to use the subjective method of measurement due to H. A. Thomas until an objective method is in use and is found to be satisfactory. In this connexion, it was opportune that Mr. H. E. Dinger (United States) described the American plans for a world-wide measurement of atmospheric noise by an objective method at some fifty stations to be installed during the next two years. In the meantime, it was urged by the chairman that measurements in the high-frequency range by the subjective method should be resumed in Australia and New Zealand; and attention was directed to the British plans to extend the world survey to lower frequencies. Mr. F. F. Gardner (Australia) gave an account of noise measurements made on a frequency of 2 Mc./s. at a place remote from sources of man-made interference. He said that by day the only noise measured was that corresponding to the thermal noise from the ionosphere, while at night the prevailing noise arose from man-made sources in a city 50 km. away. Mr. Dinger stated that at high latitudes noise due to precipitation is very important and can interrupt traffic for several hours on frequencies between 18 kc./s. and 18 Mc./s. In addition, interference is often associated with storm clouds even when there is no actual precipitation.

Concerning the future, it was agreed that at the next general assembly of the Union discussions would be held on the following topics: wave-forms and propagation of atmospherics; meteorological aspects of atmospherics; world-wide 'noise surveys'; and atmospherics as a source of interference to communication systems.

National committees were asked to encourage research in these subjects, and in particular to endeavour to provide an answer to the following question posed by the International Radio Consultative Committee: "What are the most easily measured characteristics of terrestrial radio noise from which the interference to different types of communication system can be determined?" Finally, the Commission recommended that, during the International Geophysical Year, three lines of work should be undertaken: measurements, of a high standard, of the radio noise at as many places as possible, including the polar and auroral regions; observations of the wave-forms of atmospherics, including 'whistlers', at several places, including the equatorial and polar regions; and optimum use to be made of organizations set up for the location of thunderstorms and lightning flashes.

## Radio Astronomy

Commission 5 formerly defined its scope by the title "Extra-terrestrial Radio Noise"; but at the general assembly in Zurich during 1950 it was renamed as the Commission on Radio Astronomy, and its scope was extended to include such subjects as meteors and the moon when observed by radio techniques, as well as the investigation of radio emissions from the sun and stars. The meetings of this Commission in Sydney were of particular interest in view of the large amount of research in this field which has been conducted in Australia during the past few years under the auspices of the Commonwealth Scientific and Industrial Research Organization. The visit of the Union provided a most valuable opportunity for the research workers in this field in the northern and southern hemispheres to discuss their experiences and results.

At the first of four sessions, Mr. W. N. Christiansen (Australia) described observations of solar radiation made on a wave-length of 21 cm. (frequency 1,420 Mc./s.) using a linear array of thirty-two parabolic reflector aerials along an east–west line some 240 m. long. The radiation diagram of this system comprised lobes 3′-arc wide and 1·5° apart; and continuous record was obtained as the sun passe through several lobes. The observations showed th presence of disturbed areas on the sun, closely associated with sunspots and persisting for one o two revolutions of the sun. The distribution o radiation across the disk was deduced: this showe limb-brightening corresponding to a coronal temperature of $2{\cdot}5 \times 10^6$ °K. Dr. J. L. Steinberg (France) reported observations made on solar eclipses on wave-lengths of 178 m. and 3 cm., and these could only be explained on the assumption that the solar corona was not circularly symmetrical. These results were confirmed by other observers on various frequencies between 225 and 10,000 Mc./s., and in most cases there was evidence of limb brightness. Dr. F. G. Smith (Great Britain) described interferometric measurements of the distribution of brightness across the sun on four wave-lengths between 60 cm. and 7·9 m. in an attempt to determine the distribution of temperature in the corona. It was shown that no simple model of the solar atmosphere can explain results on these wave-lengths, it being difficult to interpret the observed radiation from regions at two or three times the solar radius from the centre of the disk.

At the second session, which, like the first, was presided over by Dr. D. F. Martyn, a discussion on the dynamics of ionized media was opened by Prof. H. S. W. Massey (Great Britain), followed by contributions by Dr. Martyn, by Drs. K. C. Westfold and J. H. Piddington (Australia) and by Dr. N. Herlofson (Sweden). Some of the particular problems considered were the nature of modes in a plasma and the setting-up of oscillations with consequent radiation from plasma. It was shown that reflexion from dense meteor trails when the electric vector is not along the trail is not fully understood.

The subject of the third session was interstellar gas, and at this meeting Dr. H. I. Ewen (United States) described his work on the reception of the line radiation at 1,420 Mc./s. originating in the neutral hydrogen atoms in the galaxy. The frequency and intensity of the line were shown in the early experiments to depend on the direction of the observation. Mr. Christiansen and Dr. C. A. Muller (Netherlands) described their investigations of the variations of frequency and of the deductions which could be made about the movements of the emitting portions of the galaxy.

At the last session, Dr. B. Y. Mills (Australia) surveyed the techniques which have been used for the observation of discrete sources of cosmic radio waves. Observations made in Sydney on a frequency of 100 Mc./s. show that the more intense radio stars are concentrated towards the galactic plane. R. Hanbury Brown (Great Britain) reported results obtained on a frequency of 160 Mc./s., in which a source was discovered near the position of the supernova observed by Tycho Brahe; other sources were tentatively identified with clusters of extragalactic nebulæ. Dr. J. G. Bolton (Australia) described an extension of the sea interferometer experiments, and a new instrument for determining azimuth. He has been able to show that the angular diameter of some radio stars can be resolved.

Among the thirty-three documents distributed to this commission were several reports from national committees which present useful surveys of the very rapid progress made in recent years in this general field of radio astronomy.

### Waves, Circuits and Electronics

The interests of Commission 6 are considered to cover such fields as theory of information; theory of non-linear oscillations; linear circuit theory; and diffraction theory, antennæ and wave-guides. Various working parties were set up at Sydney to report on progress in these fields, and national committees were recommended to give serious consideration to a number of matters relevant to the theory of information and its practical application to communication matters in which the International Radio Consultative Committee had expressed particular interest.

Three sessions of the Commission concerned with electronics were held, at the first of which new developments in vacuum tubes were discussed, while the second dealt with such subjects as the dielectric properties of solids, the thermionic constants of metals and the electrical properties of thin films. The final session dealt with the fundamentals of gas discharges, the interaction of electromagnetic waves with plasma, and the radiation of micro-wave noise from gas discharges.

### Publications

Hitherto the proceedings of the General Assemblies of the Union have been published with the detailed texts of all documents. On the present occasion, the executive committee of the Union decided to discontinue the publication of the individual papers, which are either incomplete summaries of the papers presented at the sessions or are papers which are or will be published in the recognized scientific journals. A more useful objective to be pursued is to publish additional special reports on selected radio topics, and to make these universally available. Two such reports have already been published, one on "Solar and Galactic Radio Noise" and the other on "Tidal Phenomena in the Ionosphere"; and a third, on "The Dynamics of Ionised Media", is in the press. Among the subjects proposed for future reports are ionospheric storms, radio investigation of meteors, ionospheric wave interaction, interstellar hydrogen, discrete sources, and the distribution of radio brightness on the solar disk.

### Officers

At the closing meeting of the general assembly, the following officers were elected: *Honorary presidents*, Sir Edward Appleton, Dr. J. H. Dellinger and Dr. B. van der Pol; *President*, Father P. Lejay; *Vice-Presidents*, Dr. C. R. Burrows, Dr. D. F. Martyn and Prof. B. D. H. Tellegen; *Treasurer*, Prof. C. Manneback; *Secretary General*, Col. E. Herbays; and *Chairmen of Commissions*, (1) Dr. R. L. Smith-Rose, (2) Dr. C. R. Burrows, (3) Sir Edward Appleton, (4) Mr. J. A. Ratcliffe, (5) Dr. M. Laffineur, (6) Dr. L. C. Von Atta, and (7) Prof. G. A. Woonton. Delegates of the Union were also appointed to serve on various other international organizations.

In addition to the scientific meetings described above, the delegates participated in an extensive programme of technical visits and social events which displayed both the intention and the ability of their Australian hosts to make the occasion as instructive and pleasant as possible. The University of Sydney, the National University at Canberra, the Commonwealth Observatory at Mt. Stromlo, the various laboratories and field stations of the radio and electrical divisions of the Commonwealth Scientific and Industrial Research Organization were all visited, as well as some of the laboratories and works of firms in the associated industry. On such occasions, chiefly at week-ends, when no formal business sessions were on the programme, all the delegates were provided with excellent opportunities for enjoying the beautiful scenery around Sydney and farther afield in New South Wales. The hospitality shown by the Commonwealth Government and by private organizations and individuals has left a memorable impression of this visit to the only continent which lies wholly in the southern hemisphere.

# PLANKTON OF THE BENGUELA CURRENT

By Dr. T. J. HART

National Institute of Oceanography

During the two surveys of this area in 1950 that yielded the hydrological results described in a recent article by Currie[1], extensive plankton collections were made. Preliminary sorting of the zooplankton material is not yet complete—in addition to its being nearly as rich as that of polar waters in quantity, it is much more diverse in quality—and a greater expenditure of time than that required for this phase of the work on material from most other regions is therefore unavoidable. Moreover, the full value of the material can only be assessed when specialists working independently on the various groups have completed their reports. At this stage, therefore, only major features of group-distribution, rendered clear by the preliminary work on material from the first survey, have been considered.

With the phytoplankton we can already proceed much further. In dealing with it, a conservative choice of method was necessitated by practical considerations (to be stated in the main report), and our estimations for all stations on both surveys are now complete. These were made by Hensen methods from 100–0 m. hauls of the Gran net. When plotted logarithmically, they seem adequate to show up the grosser quantitative differences; for it was found that the concentrations of phytoplankton in this area were such that, whether dealing with important individual species, groups or grand totals, a 50 per cent alteration of values assigned to the contours in either direction made but little difference to their position on the chart. Moreover, scores of individual species, only one or two of which can be cited here, showed distributional patterns in good agreement with the hydrological features. The latter were, of course, quite independently assessed.

Close similarity to the conditions off Lower California in 1941, as described by Sargent and Walker[2], working from W. E. Allen's counts, is evident. They found a succession of three "plankton elements" in a large eddy of the upwelling current, with Chaetocerids predominating in the richest, most recently upwelled and coldest water, and a sparse warm-water element offshore. This last, however, was in the oldest surface water from the eddy, not in a distinct, more oceanic,

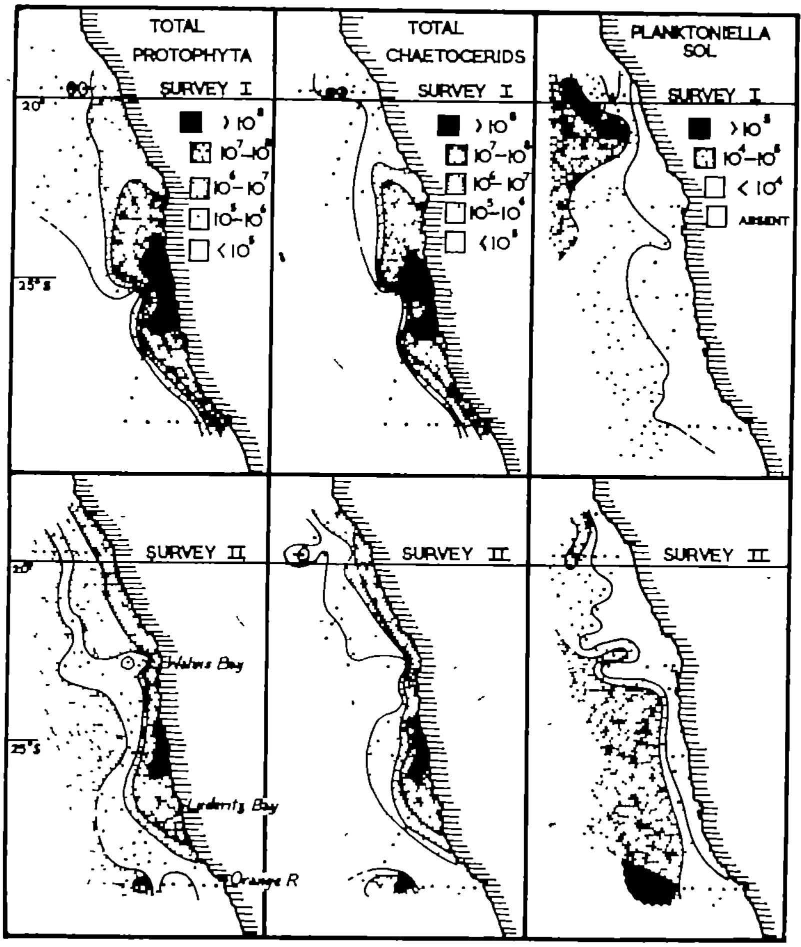

Fig. 1

body of surface water as here. It seems that in relatively narrow eddies set up in the Benguela Current, the whole circulation is more rapid, so that some 'ageing'—which involves heating—of the upwelled water must take place before peak phytoplankton production becomes possible. Even so, many of the cosmopolitan species we found so abundantly were present off California also, and though through lack of seasonal data we cannot generalize so far as Sargent and Walker have done, the close analogy between the two regions seems clear.

In the Benguela Current we found the rich catches concentrated on the shelf some 10–45 miles from the coast, in the central area from Luderitz Bay northwards, as shown to the left of Fig. 1. Species of *Chaetoceros* were so far dominant that their distribution (centre) forms an essentially similar pattern. They formed 60–90 per cent of the catch at most of the richer stations. Currie's[1] computations show that upwelling activity is normally greatest in this area.

Higher average values, and restriction of the rich area to the northward combined with a greater extension of it seaward, were features distinguishing the autumn observations (first survey) from the spring ones (second survey). Together with some marked qualitative differences, it is these which suggest that the slackening of upwelling in autumn (demonstrable from the physical data) allowed peak development of the succession. The hypothesis that such a peak may not be attained locally when the whole circulatory complex is speeded up follows as a corollary from the spring observations; for there must be a time-lag before the diatoms seeding the rich water newly arrived within the photic zone can proliferate sufficiently.

Of the various species, *Chaetoceros compressum*, *Ch. curvisetum* and *Ch. didymum* were most important, closely followed by several more (of the section Hyalochaete) of that difficult genus. *Asterionella japonica* was the most abundant pennate form able to flourish among them; but close inshore *Fragilaria karsteni* was more important. On the first survey *Eucampia zoodiacus* was quite numerous in the rich diatom zone; but on the second survey we saw none, though it was present farther south, and in colder water at that time. This may be an extreme example of the succession effect postulated above. Possibly a more directly seasonal effect was the great abundance of resting spores of *Chaetoceros didymum* in autumn, and a great scarcity of them in spring (though plenty of the normal vegetative phases were present).

The sparse phytoplankton of the offshore surface water contained relatively large numbers of *Planktoniella sol*. This distribution is shown to the right of Fig. 1. It fits the intrusions of offshore water determined by physical and chemical means very closely. The most striking example is the tongue of *Planktoniella*—rich water from the north, projecting southwards and shorewards towards the colder *Chaetoceros* zone during our first survey. Rayner (quoted by Gunther[3]) had found a similar relationship in the Peru Current, working from the same ship twenty years earlier. Clearly *Planktoniella* is a good indicator in such regions, provided that the phytoplankton is considered *in toto*.

Fig. 2 is partly a repetition emphasizing this point, but also showing another important feature. An isolated area with moderate quantities of Chaetocerids can be seen to the north of the intrusion from offshore, probably a relic of previous continuous distribution; but in the area between the two strongly contrasting diatom floras, the Dinophycean *Goniaulax spinifera* predominated. The phytoplankton here was not rich, but it is noteworthy that this was the only area sampled during the survey, more than twenty miles offshore, where Dinophyceae predominated over the diatoms. It is probably significant that here, where the distance between the two strongly contrasting types of surface water was least, one might expect lateral mixing between them to have been strongest.

On arrival at Walvis Bay during the first survey, we found that a fish mortality had occurred. Leaving

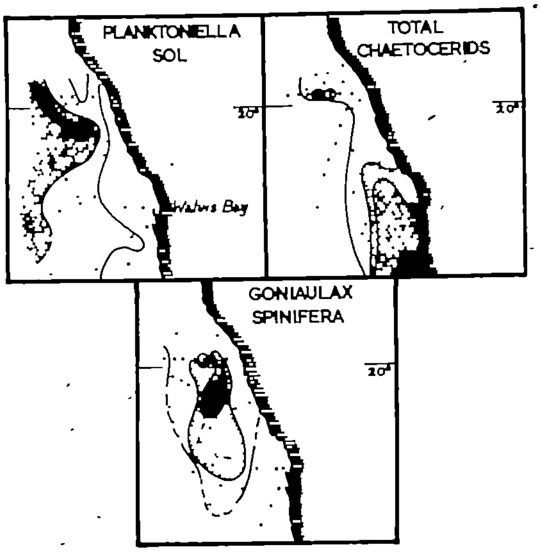

Fig. 2

next day on a south-west course we passed through large areas of discoloured water, some of them extending as far as fifteen miles seaward of Sandwich Harbour. Some of the more intensely coloured areas formed narrow bands with streaks of foam and Ctenophores disintegrating at the surface, like the wind lanes often formed in *Trichodesmium* blooms in warmer waters. Considerable congregations of sharks, sea-birds and seals were seen near by. They did not seem to be adversely affected. A series of surface samples was examined by centrifuge and drop method. *Gymnodinium* and *Gonioulax* spp. (two genera of Dinophyceæ already known to include 'lethal' species) were present, but only in very small numbers. Detailed counts of preserved material afterwards showed that a rich mixed plankton was present in the 'khaki' or 'olivaceous' areas. There were some half-million cells per litre: *Peridinium triquetrum* 39 per cent, the diatom *Asterionella japonica* 33 per cent, *Procentrum micans* 14 per cent, and most of the remainder quite large diatoms. Areas appearing more definitely brown or reddish at a distance showed *P. triquetrum* clearly dominant—more than 85 per cent of the numerical totals, which reached three to six million cells per litre. Equally heavy blooms of this very cosmopolitan, but usually more strictly neritic species, have been recorded from Scottish lochs and from inner Oslo Fjord, the latter in definitely polluted water (Marshall and Orr[5], Braarud[6]). Can it be that here this type of bloom follows rather than precedes mortalities? There is, however, one record associating this organism (under the name *Heterscapsa triquetra*) with a fish mortality at Rostock in the Baltic in 1917 (Lindemann, quoted by Brongersma-Sanders[4]). The Walvis Bay mortality had already occurred when we arrived there; but as we worked in towards the land by night, we do not know whether the bloom was already present offshore. However, it is now clear that water-blooms due to several quite different organisms may recur within this one sea area.

In some seas, blooms may be a direct cause of mortalities (as when caused by certain species of *Gymnodinium*, *Gonioulax* and other genera), but they are often quite harmless and not even coincident in point of time (*Prorocentrum*, *Amphidinium*). This is already clear from such work as that of Allen[7], Graham[8], and others. Thus Dr. Brongersma-Sanders's hypothesis[4], that mortalities near Walvis Bay are due to *Gymnodinium* poisoning, may prove quite justified, though none of the blooms I have yet been able to examine from the South African coast have belonged to that genus. We cannot yet say whether the relation between water-bloom and mortality here is causative, coincident or resultant. But we can say, from the evidence so admirably marshalled by Dr. Sanders, that bloom has often been seen at about the same time as a mortality.

For the present, Currie and I prefer to guess that the mortalities may be due to a combination of adverse factors, with oxygen shortage (below the extreme surface layer) perhaps the most important, the whole set in train by large-scale meteorological and hydrographic changes leading to slackening or temporary cessation of upwelling; the latter may involve incursions of warm surface water into the area from the north and west, though local heating must also figure largely under such conditions.

That the zooplankton of the Benguela Current is rich in quantity is obvious from the bulk appearance of the samples. Qualitatively it is much like that off Lower California and off Peru. Group sorting led to demonstration that considerable spawning of *Sardinops sagax* took place on the shelf, near the richest diatom area, early in March (Hart and Marshall[9]). Both economically and ecologically, this is the most important pelagic fish of the region. Post-larvæ reached a peak one station farther seaward than the egg-maximum on each line of stations, in accord with known water movement. Both eggs and young stages coincided with extraordinarily large catches of Cumacea in the plankton nets. Elsewhere, these mainly bottom-living crustaceans are usually subordinate to Mysidacea, except in some arctic localities. Their persistent presence here, in very large numbers, in the plankton, may have been due in part to oxygen deficiency in the lower water-layers. In March, Mysidacea predominated over the Cumacea at one station only—inshore off the Orange River.

While many cosmopolitan species abounded in the zooplankton, such as *Thalia democratica* and *Salpa fusiformis* among offshore Tunicates, and *Evadne nordmanni* among inshore Entomostraca, the important Euphausian species are more typically South Atlantic. Even so, Dr. Boden, who is now working up our Euphausians, and who has already studied Californian material, informs me that the distribution of genera and comparable species in the two areas seems most strikingly similar. The largest catches of Euphausians, especially the young stages, were taken with the richest phytoplankton (though not, of course, in the 'bloom' area) some 20–50 miles offshore.

The Ostracods from the first survey have already been reported on by W. J. Iles (in the press). They clearly formed an essentially mid-water, offshore group. Possibly their marked absence from stations over the continental shelf was due to the decrease in upwelling at that time. We already know that a few strayed farther in during the second survey.

Notable examples of group dominance were a great concentration of the Pteropod *Limacina bulimoides* offshore and near the shelf edge to the south, where we have some evidence that the phytoplankton had been heavily grazed. Large Aulacanthid radiolaria were very abundant offshore to the north, and *Acanthometron* at one shallow-water station to the south.

These examples are but a foretaste of the distributional data that we hope ultimately to extract from the material. The distribution charts I have included were redrawn for reproduction by Mr. Currie, to whom I am deeply grateful. Both of us are greatly indebted to the Director and staff of the Marine Biological Association's Plymouth Laboratory for providing unrivalled working facilities before the new premises of the National Institute of Oceanography were available.

# OBITUARIES

## Prof. J. H. Orton, F.R.S.

James Herbert Orton, emeritus professor of zoology in the University of Liverpool, died on February 2, less than four years after his retirement from the Derby chair and the directorship of Port Erin Marine Biological Station.

Before going to Liverpool in 1929, Orton had spent nearly twenty years as naturalist (latterly, chief naturalist) at the Plymouth laboratory of the Marine Biological Association. Both at Plymouth and at Port Erin, Orton conducted vacation classes in marine biology and became known to large numbers of students, among whom his infectious enthusiasm proved a means of starting many on a career of marine biology.

During his tenure of the Liverpool chair of zoology, Orton was a popular figure with his students and the younger members of his staff. He did not, however, come into very close academic touch with his students, either by lecturing or otherwise, until their later honours or research years; but at this period they found him to be a wise guide and friendly counsellor in their studies. He was ever on the look-out for potential research workers in his chosen subject, and, having found them, never hesitated to demand from them the highest standards of technical ability and assiduity. These demands never went unheeded, for they never exceeded the standard he so obviously set for himself.

Though primarily a marine biologist, Orton was keenly alive to the importance of freshwater biology; he was an active member of the Dee Fishery Board, and had served on the Council of the Freshwater Biological Association. At Liverpool, he succeeded in establishing a lectureship in freshwater biology and an active school from which important studies in pollution problems and in the life-history of the salmon have issued.

In the marine sphere, Orton produced, over a period of forty years, a succession of papers, reports and notes covering a wide range; but it was upon the biology and economics of the marine mollusca that he became an acknowledged authority, whose opinion was sought by government departments and by commercial oyster-fishing interests alike. His papers on the biology of the 'native' or European flat oyster include studies of its growth, shell-formation, sex-change, food and feeding, environment, predators and culture-methods, and together form a corpus of knowledge for one species which has scarcely been equalled in the whole realm of zoology. His other molluscan papers include work on the cockle and the limpet, and on this latter he was engaged at the time of his death. The value of his researches was recognized, in 1948, by his election as a Fellow of the Royal Society.

Orton was appointed director of the Port Erin Marine Biological Station in 1939, ten years after his taking up the chair of zoology at Liverpool. The dual task, though a heavy one, was accepted gladly because it afforded him the opportunity of guiding the destinies of a marine station—a task for which his long experience at Plymouth had fitted him. At Port Erin, Orton was manifestly at his best—always eager and cheerful; but his well-laid plans for the establishment of 'Port Erin' as a first-rate centre of biological oceanography in the Irish Sea were delayed and partly frustrated by the onset of the Second World War, during which he took up active military service. After the War, limited expansion became possible, and this was greatly aided by the provision, from University funds aided by the Development Commission, of the M.V. *William Herdman*. Plans for structural changes in the buildings of the Port Erin station were also drawn up, but these have not yet been carried into effect.

The name of James Herbert Orton will remain honoured, at Port Erin as in his department at Liverpool, as that of a man who pursued his life-work with acknowledged success, tireless devotion and utter singleness of purpose. J. R. Bruce

## Dr. A. N. Zavaritzky

Alexander Nikolaevich Zavaritzky, who died at his home in Moscow on July 23, 1952, was one of the most prominent petrologists in the U.S.S.R. He was born on March 14, 1884, in the town of Ufa, being educated at the gymnasium (grammar school) there, and then he graduated in 1909 from the St. Petersburg (now Leningrad) Mining Institute. In his capacity as lecturer in the Mining Institute, he assisted E. S. Fedorov and K. T. Bogdanovich in the work on petrology and ore deposits, and much of his subsequent scientific career was devoted to welding these two subjects together.

In 1921 Zavaritzky became a professor in the Mining Institute, but, as is usual in Russia, he combined teaching with a very active participation in the work of the official Geological Survey. At first he concentrated on the study of the magnetite ores of the Ural Mountains, especially on the ores of Mount Magnitnaya, which eventually played such an important part in the development of Soviet industry. The results of his research on the occurrence and modes of origin of these ores were published in a three-volume work in 1922–27. This work was followed by a number of publications, dealing with a great variety of subjects, among which may be singled out the ultrabasic rocks of the Urals, platinum deposits, alkaline rocks and pyrite deposits. In 1931, Zavaritzky began the exploration of the distant and difficult region of Kamchatka. He not only published valuable papers on Kamchatka's volcanoes but also organized an extensive survey of this region, and he eventually became the head of the newly established Volcanological Laboratory in Moscow and of its branch in Kamchatka. He also studied the volcanic rocks of Armenia and Manchuria. From 1945, in collaboration with L. G. Kvasha, he began the reorganization of the extensive meteorite collections of the Soviet Union. He also published a number of papers dealing with minerals, microscopical methods and apparatus. In addition to several text-books, Zavaritzky published two important books dealing with the physico-chemical principles of the formation of igneous rocks (1926) and the petrochemistry of igneous rocks (1944). A general account of his scientific work has already appeared in *Nature* (157, 378; 1946), and a number of his works have been abstracted (*Min. Abstr. Min. Mag.*). A summary of recent work on the volcanoes of Kamchatka has been published in the *Bulletin Volcanologique* (Ser. 2, 8, 87; 1949).

In 1939 Zavaritzky was elected a member of the Academy of Sciences and moved to Moscow, where he occupied a number of important scientific posts, combining administration, research, editorship and teaching. All his published work is characterized by a remarkable thoroughness and by lucidity of exposition. He was a first-class petrologist and an outstanding specialist on ore deposits. As a teacher, research worker and organizer, Zavaritzky will long be remembered in the U.S.S.R. and his death lamented by his numerous friends, colleagues and pupils.

S. I. TOMKEIEFF

## Dr. J. A. Hewitt

THE death on March 10 of Dr. James Arthur Hewitt robs preclinical circles in the University of London of a figure well known for more than thirty years. He was born in 1889, and after being at Glasgow High School and Hutcheson's Grammar School, he took a B.Sc. in St. Andrews in 1911, with special honours in chemistry, natural history and physiology. He became assistant to Prof. P. T. Herring and later senior assistant, acting as head during the prolonged absence of the professor.

On the outbreak of war in 1914, he joined the Royal Artillery, in which he had a very varied career, being attached at first to the Royal Flying Corps. Later he became a staff officer, Southern Command, specially concerned with anti-gas warfare. He was himself seriously gassed earlier, a fact which led to much subsequent ill-health.

On his return from service, Hewitt joined Prof. W. D. Halliburton at King's College, University of London, and collaborated with him in the first production of *Physiological Abstracts*, a landmark in medical literature. At first, he was a biochemist, obtaining his D.Sc. for researches in carbohydrate metabolism, but he was so extremely versatile that he was able at a later date to take over the teaching of histology from the late Dr. Da Fano. As a teacher he was superb, and he picked up new material easily. At one time, he even gave a course of advanced lectures on the nervous system before the work of Sherrington was so generally appreciated. His election to the chairmanship of the Board of Physiology of the University of London was eloquent of the appreciation of his personal qualities. This was the first time a non-medical man had been elected. He was elected F.R.S.E. in 1947.

He became increasingly popular with young people. While evacuated to Birmingham during 1941, he became a squadron-leader in the A.T.C., and on leaving was given a complimentary dinner. Many will remember, too, his enthusiasm for motor-cars, especially old crocks which he loved to take to pieces and get into working order. Only two years ago he took part in an important rally.

Hewitt will be remembered by his kindly way with students. As adviser to medical students at King's College, he was ever zealous in their interests, and many owe their careers to his insistence with difficult authorities. We all regret his passing.

R. J. S. McDOWALL

# NEWS and VIEWS

### Presidency of the Royal Aeronautical Society: Sir William Farren, C.B., F.R.S.

SIR WILLIAM FARREN has been elected president of the Royal Aeronautical Society for the year 1953–54 and will take office at the annual general meeting of the Society to be held on May 7. Sir William was born in Cambridge in 1892 and was educated there at the Perse School and afterwards in the University at Trinity College. After a short spell as an electrical engineer, he joined the Royal Aircraft Factory at Farnborough in 1915 and was in charge of the experimental and design aspects of aerodynamics there until the end of the First World War. From 1920 until 1937 he worked in university circles, being a lecturer at various times in engineering, aerodynamics and aircraft structures at Cambridge and at the Royal College of Science, London. Sir William then abandoned academic work and became deputy director of scientific research at the Air Ministry, rising to the post of director of technical development at the Ministry of Aircraft Production in 1940. The succeeding year he returned to Farnborough as director of the Royal Aircraft Establishment, and the five and a half years during which he held this post (in which he incidentally found the time to take up active flying again) were marked by a great increase in the staff, buildings, equipment and general activity in the Establishment. After the War, it was fitting that Sir William should decide to employ his energies in the aircraft industry, and since 1947 he has been technical director of A. V. Roe and Co., Ltd. His many achievements were acknowledged by his election to the Royal Society in 1945 and by a knighthood last year.

### Royal Geographical Society: Awards

THE Queen has approved the award by the Royal Geographical Society of Royal Medals as follows: *Founder's Medal*, Mr. P. D. Baird, director of the Montreal office of the Arctic Institute of North America, for explorations in the Canadian Arctic; *Patron's Medal*, Count Eigil Knuth, leader of the Danish Expedition to Peary Land in 1948–50, for explorations in northern Greenland and for contributions to Eskimo archæology.

The Council of the Society has made the following awards: *Victoria Medal*, Sir John Myres, emeritus professor of ancient history in the University of Oxford, for contributions to the geographical history of Greek lands and for his services to the development of geography in education; ***Murchison Grant***, Mr. G. B. Stigant, hydrographic department of the Admiralty, for studies and mapping of the Japanese coasts; ***Back Grant***, Mr. G. de Q. Robin, senior British scientist on the Norwegian–British–Swedish Antarctic Expedition of 1949–52, for geophysical explorations in Queen Maud Land; ***Cuthbert Peek Grant***, Mr. Duncan Carse, leader of the South Georgia (Antarctic) Expedition of 1952, for exploratory surveys and mapping; ***Gill Memorial***, Mr. B. H. Farmer, Fellow of St. John's College, Cambridge, for studies of the use of land in Ceylon.

### Secondary Technical Schools and Industry

In his presidential address on March 21 to the Association of Heads of Secondary Schools, Mr. H. B. Brown, headmaster of the Bordesley Green Technical School, Birmingham, referred to the development and present position of secondary technical schools, and pointed out that these schools demand of their pupils a very exacting standard of mental activity with an application tending to combine a comprehensive theory with sound practice. He suggested that industry could feel that the time a pupil spent in such a school after the normal school-leaving age is a real contribution to his or her training and might provide the background for later employment in administration, supervision or design. He recommended that training of a young person for a responsible post in industry or commerce should be regarded as divided between full-time school attendance, instruction within industry and special training, either in industry or in further-education establishments, the whole directed towards developing suitability for a position requiring special skills, aptitudes and responsibility. Mr. Brown looked for more co-operation between industry and the technical schools and expressed concern at the inadequacy of the present supply of teachers of science, applied science and crafts, a shortage which threatens the whole of the science and craft teaching in schools, and which may have repercussions on industry itself. He insisted on the need for technical schools to keep their methods of teaching and curricula, their relations with industry and the needs of the cultural world constantly under review and to anticipate and meet changing demands. It is a principal function of the Association, he maintained, to assist in co-ordinating the professional outlook of its members.

### Investigation at Cambridge of the Feldspar Minerals

The Nuffield Foundation has offered a grant of £4,150 in aid of a research project on phase equilibrium relations and atomic structure of the feldspar group of minerals to be undertaken jointly by the Department of Mineralogy and Petrology and the Crystallographic Section of the Cavendish Laboratory at Cambridge. The application of recently developed techniques for feldspar synthesis under controlled conditions and for the rapid X-ray identification of crystalline phases, principally at the Geophysical Laboratory of the Carnegie Institution of Washington, has opened up a fruitful field of research of the first importance, not only for the understanding of the intimate relations within this great mineral group but also for the elucidation of the genetic history of feldspathic rocks, both igneous and metamorphic. The grant provided by the Nuffield Foundation will be utilized at Cambridge for the provision of equipment devised for the application of the new techniques in the investigation of the hydrothermal synthesis, polymorphism and unmixing relations of feldspar phases, and for fundamental crystal analysis studies, especially of synthetic feldspars of known thermal history.

### Enzymic Systems in Root Apices

An account of a method for determining the development of the enzyme complement in growing root cells has been given by E. Robinson and R. Brown (*J. Exp. Bot.*, 3, 9, 356; 1952). On corresponding successive segments from the root apex backwards, the water and protein contents and the activities of dipeptidase, glycine oxidase and invertase have been measured, together with the number of cells in each segment. From these data it has been possible to indicate how the quantities involved change during cell growth. Four phases can be distinguished in the early cellular development. During a cell's development in the meristematic region its volume increases slightly, the protein content probably decreases, and the activities of three of the enzymes studied decrease. During the second phase there is a large increase in cell volume and protein content, and all enzymic activities increase considerably. In the third phase, the cell increases in volume by increase in breadth, but its protein content and enzyme activities decrease. The fourth phase is marked by cessation of growth and a continued decrease in protein content and enzyme activity. In discussing their results, the authors point out that the enzyme activity varies directly with the protein level during all four phases, and that the enzymatic constituents account for, if not the whole, at least a considerable part of the total protein content. The possibility is considered that during cell growth there are changes in the composition and structure of the protein complex and that such changes are causally related to variation in the relative activities of the different enzymes. Whether cell growth is determined by changes in the protein contents and other related topics are discussed.

### Stop-watches and Chronographs

Instruments capable of measuring and recording intervals of time to a fine degree of accuracy are required in many walks of life and particularly by the engineer and scientific worker in modern industry. Stop-watches and chronographs are mainly used; but few people understand the underlying mechanism, the degree of accuracy that can be expected and how to select the most suitable type for the work to be measured. The completely revised and reprinted catalogue of high-precision Swiss stop-watches and chronographs, recently issued by the firm of Camerer Cuss and Co. (54–6 New Oxford Street, London, W.C.1), which has specialized in horology since 1788, is, in spite of its small size, particularly valuable because it contains, in a preface, just those details which will assist the purchaser in the selection of the correct instrument. The function and action of the escapement is explained, how inaccuracies are reduced by proper choice of materials and arrangement is discussed, and the necessity is stressed for a periodical overhaul if a watch is to maintain a steady state. Where it is necessary to have a certificate of accuracy, the Metrology Division of the National Physical Laboratory, Teddington, will undertake an independent test. Watches required for the testing of electric meters are tested under the Electricity Supply (Meters) Act, 1936, to a specification issued by the Ministry of Fuel and Power. The instruments illustrated and described in the catalogue are of various types, including three-pressure action, instantaneous fly-back and restart, and split-second stop-watches and chronographs with time of day and of the wrist pattern. All Camerer Cuss instruments contain the jewelled pallet-lever escapement, a superior pattern, and are jewelled in all the principal bearings.

### Wave-lengths for Radial-Velocity Determinations of Stars

A PAPER on "Wave-Lengths for Radial-Velocity Determinations based on Measures of One Hundred F- to M-type Stars" has been published by K. O. Wright in *Publications of the Dominion Astrophysical Observatory, Victoria, B.C.* (9, No. 3, 167–180; 1952. Ottawa: Queen's Printer. 25 cents), which gives the results of the author's investigations begun in 1936 when he went first to the Dominion Astrophysical Observatory. Most of the plates that were measured had been previously taken for the absolute magnitude programme of Young and Harper, an account of which appeared previously in the *Publications* (3, 1; 1924), and were well exposed in the range 4000–4500 A. As many of these observations covered epochs not observed elsewhere, it was decided that the plates should be measured for radial velocities. Unfortunately, Wright's activities were transferred elsewhere when he had completed the measurement of about one-half of the plates; but the results obtained have proved very useful. One object of the measurement was to check the wave-lengths used in radial-velocity measurements of late-type stars, and preliminary velocities were derived by using Petrie's system of wave-length standards (described in *Contrib. Dom. Astrophys. Obs.*, No. 4, 1946). The results for each line have been averaged for each spectral type from *F*4 to *M*8 on the Young and Harper system (*Pub. Dom. Astrophys. Obs.*, 3, 1; 1924), and the variation of velocity difference with spectral type has been the chief criterion in selecting the lines used in the investigation. The general results confirm that the "Lick Catalogue" (*Pub. Lick Obs.*, 18; 1932) and the "New General Catalogue" (*Pub. Lick Obs.*, 16; 1928) are, effectively, on the same scale and show that the velocities obtained are, on the average, 0·9 km./sec. more negative than the Mount Wilson velocities in the new catalogue. A list of nine stars is given of which the radial velocity may be variable, and only one of these has been previously announced by the Lick Observatory. The range of velocity in these stars is at least 8 km./sec., and, as an individual measurement should not be in error by more than 2 or 3 km./sec., it is considered probable that the variation in these stars is real.

### Conference on Organic Evolution

THE National Institute of Sciences of India, encouraged by Dr. S. S. Bhatnagar, recently celebrated the presence in India of the distinguished German biologist, Prof. Bernhard Rensch, by organizing a conference on organic evolution at New Delhi during March 6–8. The programme and abstracts issued by the convener, Dr. Sunder Lal Hora, show that more than fifty papers were read and discussed, half of them being by non-Indian contributors. Four of the papers are by Prof. Rensch and his colleagues on problems of relative growth; four more are by eminent Western scientists, including the veteran French zoologist, Dr. Louis Fage (on subterranean evolution), and the American pioneer on fœtal behaviour, Dr. Lester W. Sontag; and eighteen are by leading British biologists, including Prof. J. D. Bernal, Dr. W. E. China, Prof. J. B. S. Haldane, Mrs. Haldane (Dr. Helen Spurway), Dr. S. M. Manton, Prof. P. B. Medawar, Dr. Joseph Needham, Dr. C. F. A. Pantin, Dr. O. W. Richards, Dr. E. S. Russell, Dr. W. R. Thompson and Prof. F. E. Zeuner. The preface notes that all the British contributions, and some of the others, were secured by Mr. Cedric Dover. These names are by themselves a guarantee of a lively and important symposium, and the abstracts indicate that some of the most fundamental concepts of biology are directly attacked or implicitly discarded by the proposal of new approaches. Some papers, led by those of Drs. Pantin and Manton, are concerned with functional morphology; and several Indian contributions are obviously inspired by Dr. Hora's biogeographical theories. The gene theory is not favoured by some authors, while others have written within its conventions; and, though the idea of adaptations in one way or another is almost a keynote of the symposium, it is also seriously criticized and modified, especially by Drs. Russell and Thompson. Indian biologists are not as well represented as they might have been if the organization could have been more leisurely; but the abstracts suggest that papers of wide general interest have been provided by Drs. E. K. Janaki Ammal, C. P. Gnanamuthu, A. K. Ghosh and A. Bose, Sunder Lal Hora, K. and C. Jacob, H. K. Mookerjee, Sivatosh Mookerjee and M. L. Roonwal. A whole number of the *Bulletin of the National Institute of Sciences of India*, which will be published within the new few months, will be devoted to this symposium.

### Society for the Bibliography of Natural History

THE annual general meeting of the Society for the Bibliography of Natural History was held at the British Museum (Natural History) on March 30. Mr. Walter Necker spoke on "The Unsystematic Systematist, and Other Random Observations on Bibliography in England and America". It was reported that preparations were actively going forward for the production of the first part of the third volume of the Society's *Journal*. The following officers of the Society were declared elected: *President*, Dr. J. Ramsbottom; *Honorary Secretary and Treasurer*, Mr. A. C. Townsend, British Museum (Natural History), Cromwell Road, London, S.W.7; *Committee*, A. G. Davis, W. N. Edwards, F. C. Fraser, F. J. Griffin, W. T. Stearn and C. Kirke Swann.

### Laboratory Animals Bureau Congress

THE sixth Laboratory Animals Bureau Congress was held at the Royal Veterinary College, London, during March 27–28. Some two hundred and fifty technicians from all parts of Great Britain attended. The Congress was opened by the secretary of the Medical Research Council, Sir Harold Himsworth. Six short papers were read by technicians, and one long one, on reproduction in mammals, by Dr. I. W. Rowlands, of the Agricultural Research Council Institute of Animal Physiology, Babraham. Visits were paid to the National Institute for Medical Research, Mill Hill, and to the Lister Institute at Elstree, and a programme of films of zoological interest was shown at the College. Chairmen at the four sessions were Prof. S. P. Bedson, Dr. L. Harrison Matthews, Dr. R. Lovell and Prof. R. E. Glover. As in previous years, the Animal Technicians Association held its annual general meeting at the time of the Congress. The proceedings of the Congress will be published in full in the *Journal of the Animal Technicians Association*.

### Applied Microbiology

MICROBIOLOGY is now well established as a scientific discipline, and the publication of the results of fundamental research is fairly well catered for in the journals of the scientific societies. In recent years the application of microbiology to the manufacturing and food industries, to agriculture, and to the many fields in which control of micro-organisms is demanded, has resulted in the presentation of many papers of undoubted value which would, however, be out of place in journals devoted to fundamental research. Many industries, and even branches of industries, now publish the results of applied research, including microbiology, in their own journals. The Society of American Bacteriologists, by sponsoring a new journal, *Applied Microbiology* (The Williams and Wilkins Co., Baltimore 2, Maryland, U.S.A., 6 numbers, bimonthly, per volume annually 63*s*.), evidently considers that there is a place for yet another journal designed, to judge from the general statement of aims and from the list of members of the editorial board, to embrace all fields except animal and plant disease. The project is ambitious, and to achieve the apparent object there will have to be careful selection of papers, to avoid wandering into territory already catered for. The first number (January 1953) contains a catholic collection of papers, of which some at least have that wide appeal necessary to justify the appearance of another journal which must be read.

### New York Zoological Society: Aid for Biological Research in Europe

THE New York Zoological Society has renewed for 1953 its 'Point Four' programme of aid to biological research in Europe. In 1952 the Society made grants for research to individuals and institutions in Austria, Belgium, Denmark, England, France, Germany, Holland, Italy, Spain, Sweden, Switzerland and Turkey. This year funds will again be made available to research departments or individual investigators in universities, natural history museums, zoological parks, aquariums and non-profit biological laboratories. The use of funds is limited to the purchase of specific items of research equipment, books and technical journals, and the costs involved in providing experimental material. It is not intended to provide assistance to personnel of medical institutions, commercial laboratories, government-sponsored programmes or any programme concerned primarily with applied or economic biology; however, individuals or groups in such organizations are eligible for aid in connexion with any fundamental studies of their own which are being carried out simultaneously but separately. Applications for grants should be addressed to Dr. Ross F. Nigrelli, chairman of the New York Zoological Society European Research Fund, Zoological Park, New York 60, N.Y.

### Insects of Micronesia

THE Bernice P. Bishop Museum, Honolulu, is now supporting the project known as "Insects of Micronesia" which was hitherto carried on by the Pacific Science Board of the United States National Research Council with funds from the Office of Naval Research of the United States Navy; the National Science Foundation, Washington, D.C., has made a grant of 15,200 dollars to the Bishop Museum to help in continuing the work for the next eighteen months. The project is under the direction of J. Linsley Gressitt, and the results will be published by the Museum as a special series. About four hundred thousand specimens have been assembled from Micronesia, and these are being studied by more than a hundred specialists representing some fifty institutions in a dozen countries. J. F. Gates Clarke, N. L. H. Krauss and Dr. Gressitt have been completing the field-work in the Caroline Islands during 1952–53 under a contract by the Office of Naval Research.

### Announcements

THE Stas Medal of the Société Chimique de Belgique was presented to Prof. F. A. Paneth, professor of chemistry in the University of Durham, on the occasion of the general meeting of the Society on March 22.

PROF. JEAN LERAY, of the Collège de France, Paris, has been elected a member of the Mechanics Section of the Paris Academy of Sciences in succession to the late Prof. E. Vessiot. Prof. Christian Champy, professor of histology in the University of Paris, has been elected a member of the Anatomy and Zoology Section of the Academy in succession to the late Prof. C. Pérez.

THE National Coal Board has appointed Mr. A. Whitaker to be director of extra-mural research. In addition to its own research establishments at Stoke Orchard and Isleworth, the Board has extensive research interests in several research associations and also sponsors projects at a number of universities and with commercial firms. This work will in future be directed by Mr. Whitaker, who will be responsible to the director-general of research at headquarters, Dr. W. Idris Jones. Mr. Whitaker is a physicist; during the War he was with the Parnall Group of companies and was awarded the O.B.E. for work in connexion with aircraft equipment.

THE Zoological Society of London is offering a limited number, not exceeding six, of research studentships to senior undergraduates reading zoology, tenable during the summer vacation for a minimum period of four weeks at the Society's Gardens, Regent's Park, or at Whipsnade Park, where laboratory and other facilities are provided. Work which includes observations on living animals will be given preference; experiments requiring licences are not allowed. Grants in aid of travelling expenses and a subsistence allowance for those living away from home may be awarded. Applications, giving particulars of the applicant's age and attainments and a brief outline of the work proposed, and supported by the head of the department in which he or she works, should be sent before April 30 to the Director, Zoological Society of London, Regent's Park, London, N.W.1.

IN a paragraph in *Nature* of February 21, p. 332, entitled "A Dominant Sex-linked Mutation in the House Mouse", summarizing a paper by E. D. Garber published in *Science*, 116, No. 3004 (1952), the gene 'bent-tail' and its morphological effects were described. Dr. D. S. Falconer points out that he had already recognized a sex-linked gene, 'tabby', with morphological effects in the mouse (see *Nature*, 169, 664; 1952).

# DISTRIBUTION OF ANIMALS AND PLANTS IN AFRICA

A WHOLE-DAY meeting of the Linnean Society of London was held in the Society's rooms at Burlington House on January 29. The subject for discussion was "Problems of Distribution of Animals and Plants in Africa". In opening the meeting, the president of the Society, Lieut.-Colonel R. B. Seymour Sewell, stressed the importance of a sound taxonomic background to studies on distribution. Only when one knew with what species one was dealing was it possible to answer questions regarding its place of origin, method of spread and eventual isolation. Other studies of importance to the biogeographer were palæontology and climatology, including the study of past climates.

The first paper was read by Mr. E. Milne-Redhead, of the Royal Botanic Gardens, Kew, who dealt with the distributional ranges of flowering plants in tropical Africa. Of the three arid regions, the Sudanese is by far the poorest and the south-western the richest floristically. The northern savannas exhibit drier (Sudanese) and wetter (Guinean) zones characterized by the presence, in the former, of numerous species of *Acacia* and, in the latter, of *Isoberlinia*. *Brachystegia*, which is abundant in the wetter part of the southern savanna, is absent from the corresponding zone of the northern. An additional feature of the southern savannas is the presence of a thicket vegetation in the dry areas of central Tanganyika. The Kakamega forest marks the extreme eastern limit of the Congo forest, which was at one time much more extensive in Uganda than it is to-day. The vegetation of Uganda is now largely secondary and very difficult to classify. The existence of a complete gap in the dry area of the Gold Coast and Togoland is to be noted, as is the constriction of the Congo forest in the neighbourhood of the 15th meridian, which may mark the site of a former route for migration between the northern and southern savannas. The extension of forest into the savannas in the form of fringing forests along the rivers should also be noted. The small relict areas of lowland forest along the east coast are floristically different from the Guinean and Congo forests. Mr. Milne-Redhead concluded by describing distributions of individual species illustrating points of special interest. He ended with an appeal to zoologists to restrict the term 'Ethiopian' to the territory formerly known as Abyssinia instead of applying it, as now, to tropical Africa as a whole.

Mr. R. E. Moreau, of the Edward Grey Institute, Oxford, followed with a paper on the distribution of African evergreen-forest birds. He began by stating that, contrary to general belief, birds are excellent zoogeographical material. Those of tropical Africa are very strictly confined to their habitats, so much so that where the latter form isolated ecological islands the avifauna frequently shows a high degree of subspecificity, an indication of the thorough reproductive isolation of populations even when these are in close geographical propinquity. Over most of tropical Africa the 5,000-ft. contour forms the lower limit of the montane forest birds; but in certain areas, as in the mountains near the Indian Ocean, the transition takes place at altitudes as low as 3,000 ft. Broadly speaking, it may be said to take place between the annual isotherms of 18° C. and 21° C. Owing to the present very great restriction of most of the African montane forests and their isolation from the lowland forests, due partly to a dry climatic cycle and partly to human exploitation, it can only be studied in unbroken series in some areas of the eastern Belgian Congo and, on a smaller scale, on hills near the Indian Ocean. It is a remarkable fact that even in such areas as these the avifauna of the montane forest is almost as different from that of the lowland forest as it is from that of the savanna. Despite this, however, many montane species have a wide distribution in isolated forests. (An extreme example is afforded by the resemblance of the Cameroon Mountain avifauna to that of East Africa.) As against this the Abyssinian mountain fauna is much poorer than might be expected, while the degree of subspeciation even on closely adjacent mountains in East Africa is high. In conclusion, Mr. Moreau suggested some possible features of the climatic history of the continent which might help to account for these facts. Viewed *in toto*, however, the problem of the origins of the present distribution of forest birds remains a most baffling one.

The last paper of the morning session was read by Dr. A. T. Hopwood, of the British Museum (Natural History), on the origin and history of the African mammalian fauna. He began by stressing the difficulty of dating the available fossil remains. This arises mainly from two causes, the virtual absence of marine deposits and the difficulty of distinguishing ecological differences from differences of age. Like the birds, the mammals tend to be closely restricted to their preferred habitats, and in consequence distinct savanna and forest forms may be found in close geographical proximity. Oligocene deposits are rich in Hyracoidea and Proboscidea, both of which are probably African in origin, although the Oligocene Proboscidea of Baluchistan have some very primitive features. The Oligocene of the Fayum and of Baluchistan is also very rich in anthracotheres. Large collections are available from the Lower Miocene of Central Africa. These have not yet been fully worked out; but the fauna is known to have contained primitive mastodons, very close to those of the Upper Oligocene of Baluchistan, well-developed chrysochlorids (an apparently autochthonous group) and many rodents and creodonts as well as the earliest known fossil aardvark. The latter may possibly have been a Lower Miocene or Oligocene invader. The Miocene fauna of Kenya shows a close resemblance to that of south-west Africa, except that the latter contains no primates. No Pliocene remains are yet known. The Pleistocene fauna shows a very close resemblance to that of the recent era, many forms being scarcely even specifically distinct. Hippopotamus and giraffe first appear in Africa in the Lower Pleistocene and were almost certainly invaders from Asia, perhaps from India.

In the afternoon the chair was taken by Dr. W. E. Swinton. Mr. P. F. Mattingly, of the British Museum (Natural History), opened the session with a paper on the distribution of African mosquitoes. He began by discussing the climatic limits of Chapin's faunal districts, speaking mainly with reference to the subgenus *Stegomyia*. Only two species of this subgenus are naturally distributed throughout the Upper and Lower Guinean Forest districts, an example of the exclusive nature of the evergreen forest. Both species extend into the surrounding savannas. To the north they are limited by the 40-in. isohyet which here seems to form the natural boundary of the West African subregion. To the east they extend into the Kakamega forest, and the limit here seems to be an altitudinal one, about 5,500 ft. in the case of one species and about 6,000 ft. in the case of the other. To the south this difference allows one species to spread up on to the Rhodesian plateau, while arresting the other at about 3,500 ft. and confining it to the western subregion. Evidence was brought to show that the effect of rainfall on distribution may be largely indirect, the operative factor being the subsoil water-level which determines the nature of the vegetation, and so of the microclimate. The existence of a West African savanna species with a discontinuous distribution in the coastal area of Natal and Zululand indicates a former much wider extension of the central African forests. The affinities and distribution of the East African Highland fauna were discussed, and attention was directed to the existence of a typical member of the African group of *Stegomyia* in a restricted area of eastern Asia. This was discussed in relation to the origins of the African fauna, and notes were given on geographical variation and the zoogeography of introduced species.

Prof. P. C. C. Garnham, of the London School of Hygiene and Tropical Medicine, then read a paper on the distribution of blood protozoa in Africa. He said that, with the exception of a few groups of special importance, this was practically a virgin field. In addition to the two factors discussed by previous speakers, the organism and its environment, it was necessary to take account of two more, the host and the vector. There could be no zoogeography of the blood protozoa *per se* but for the fact that there occur cases in which the host and the vector are present but the parasite is not. The factor of human interference was of special importance because man could act separately on parasite, host or vector, exterminating or reducing them or increasing their numbers by importation, domestication or transportation to more suitable environments. The best parasites to study would be those whose hosts are static or have a limited range. Unfortunately, data concerning these are scanty. Examples were then given from the malaria parasites, of which the human forms occur throughout Africa, except in deserts and above certain altitudes (about 9,000 ft. in equatorial latitudes), the related Hæmoproteidæ, the hæmogregarines, the trypanosomes and the piroplasms, all of which show interesting examples of discontinuous or restricted distributions.

Dr. W. E. Kershaw, of the Liverpool School of Tropical Medicine, followed with a short paper on the distribution of human filarial parasites in West Africa. He said that the distribution of these parasites could be related in varying degrees to the vegetational zones, though less clearly than in free-living animals. The human parasite *Loa loa* occurs, it is believed, also in monkeys. It is transmitted by biting flies (*Chrysops*), which feed on monkeys in the canopy and on man either on the ground or in houses built on ridges level with the canopy. The parasite is confined to the evergreen forest and disappears as soon as the forest fringe is crossed. *Acanthocheilonema perstans* is also ubiquitous in the forest and absent from the mountain grassland, despite the presence there of one of its vectors (*Culicoides* spp.). It is also abundant, however, in the arid, eroded grasslands of the Bauchi plateau. It seems, therefore, that, in this case, very different vegetational zones can provide suitable conditions for the maintenance of the parasite.

This session concluded with a paper by Dr. E. B. Worthington, of the Conseil Scientifique pour l'Afrique au Sud du Sahara, on the distribution of freshwater organisms. He said that the continent could be divided into ten aquatic regions, but confined his remarks mainly to the eastern and central area comprising six regions, the Nilotic, Victorian, Tanganyikan, Nyasan, Zambesian and East Riverain, pointing out that these were not all coincident with drainage basins because in some cases differences in ecological conditions formed more potent barriers than dry land. Small freshwater organisms and even fish may become airborne at times. Discussing the mode of origin of present-day distributions, he suggested a hypothesis, based on past tectonic and climatic changes, to account for the picture now presented by the great lakes of East Africa. This hypothesis, he said, had first been put forward twenty years ago, but it had stood the test of time and still seemed worth restating. Active work was in progress and details were continually being filled in. Finally, he directed attention to the great interest of studies on such phenomena as the *Haplochromis* species swarms of Lake Victoria for general evolutionary theory and for our understanding of the mechanism of speciation. He said that, despite criticism, he still adhered to his opinion regarding the importance, in this connexion, of the absence of predators. He concluded by referring to the factor of human interference. This had a long history but had recently been intensified by such developments as fish farming and the use of fish in the control of disease. In some cases it was irretrievably altering local conditions before sufficient had been learnt about them.

The whole of the evening session was devoted to an open discussion. Contributions of the principal speakers will be published in full, with a report on the discussion, in the *Proceedings of the Linnean Society*.

P. F. Mattingly

# THE BIRTH OF FLIGHT*

### By the Right Hon. LORD BRABAZON OF TARA, P.C.

ALTHOUGH from earliest times smoke must have been noticed to arise from fire, it was not until the eighteenth century that the brothers Montgolfier realized the principle of using hot air to make a balloon rise. Yet such a primitive people as the Australian aborigines invented the boomerang, which aerodynamically shows three remarkable characteristics: the lift obtained from a surface which is flat on the underneath but curved on the top; the recession of the axis of rotation due to a force on one side of the rotating body; and the auto-rotating effect of a boomerang due to the change of kinetic energy into rotational energy (at the end of its flight the boomerang rotates more violently than when launched).

Nature provides a varied selection of methods of flight. Thus there are the gliding seeds, of which a number among the conifers give remarkably long glides, and auto-gyration in Nature is illustrated by the fall of an ash seed which, with but one wing, rotates at a high speed and can be carried a long way by the wind. The flapping wing is the most obvious mechanism of flight observed in the animal world; but the position occupied by birds both in normal flight and in landing clearly shows the impossibility of designing a machine along these lines by an engineer.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on February 20.

Mr. R. T. Parham, of the Society of Model Aeronautical Engineers, has built two remarkable flying models (demonstrated during the Discourse): one a helicopter which remains almost stationary in mid-air, and another of the flapping wing type, weighing complete less than ¼ oz., which performs most creditably.

It is curious that nobody seems to have studied the gliding of birds with wings of high aspect ratio (that is, long and narrow), such as the gull or albatross, which can achieve a gliding angle of about 1 in 12 (though modern gliders can now exceed this, the limit being about 1 in 42); had this type of gliding in Nature been studied earlier, there is nothing that our ancestors could not have constructed along these lines, even with the materials available two thousand years ago.

Sir George Cayley (1774–1857) was a pioneer who should be remembered, for not only did he invent the hot-air engine and the tension-spoke wheel, but he also made very remarkable model gliders. Cayley had correspondence with Stringfellow regarding the building of a big machine with steam engines, and a quotation from one of his letters—"We must go slow, I assure you before flight is safe a hundred necks will be broken"—is a classical understatement in prophecy.

The Royal Aeronautical Society was born in 1866; but it was not until 1896 that Lilienthal, a very great man, started his series of glides which may be looked upon as the basic beginning of modern flying. Chanute biplanes with movable surfaces were the inspiration of the experiments in gliding made by the Wright brothers, and in 1902 they made more than a thousand glides, some as long as 600 ft. in winds up to 36 m.p.h.

Putting to one side the flights of Santos Dumont with powered airships early this century, the history of power flight is marked by the experiments in 1894 of Sir Hiram Maxim and by the machine which S. P. Langley built in the United States. After efforts had failed to launch the Langley machine from the air off a scaffolding instead of along the ground, the experiments were abandoned on December 8, 1903, and nine days later, on December 17, the Wright brothers made their first flight; whether Langley's machine would or would not have flown is problematical, but if it had been launched another way it certainly should have risen.

Remarkable developments in the construction of engines were made by the French with their rotary radial engine and the V-type *Antoinette*. The great *Antoinette* machine flown by Latham only just failed to cross the English Channel on two occasions, and this feat was achieved by the Blériot machine in 1909 with its three-cylinder air-cooled engine. Although the Americans and French would appear to have dominated the early stages of power flight, yet the British achievements with machines flown by Cody, Roe, Moore-Brabazon and others should not be overlooked, and remarkable work was done by Edward Busk at the Royal Aircraft Establishment well before the First World War.

# PARLIAMENTARY AND SCIENTIFIC COMMITTEE

## ANNUAL REPORT FOR 1952

THE annual report of the Parliamentary and Scientific Committee for 1952* lists addresses and discussions at meetings of the general committee during the year. Included among these addresses are that by Lord Woolton on government organizations concerned with research and technology, by Dr. J. B. Conant on Anglo-American scientific relations, by Mr. T. M. Herbert on "The Present Scope of the Railway Research Programme" and by Sir Andrew McCance on "Application of Research in the Steel Industry". Addresses were also given on "Management and the Better Use of Science and Technology in Industry", and, followed by discussions, on "Foot-and-Mouth Disease" and the "Shortage of Science Teachers and its Consequences".

The report records the motion tabled on December 5 by Mr. Austen Albu but not debated; this motion, after recording the necessity for a great expansion in exports—particularly of those goods which require for their design and manufacture a high degree of research, technological development and scientific organization of production—urged the Government to take all possible steps to accelerate the more intensive application of the results of research and scientific discovery. For that purpose, it recommended that particular attention should be paid to the importance of ensuring: (1) adequate and long-term arrangements for financing industrial and agricultural research, whether by individual firms, research associations, government establishments or other means, and all consequential action necessary to ensure the fullest appreciation and application of the results of that research; (2) the use of the capital investment programme to encourage more rapid and effective applications of the results of scientific research in the agricultural, industrial and Colonial fields, with adjustments of taxation to assist small businesses engaged on work of scientific development; (3) the provision of the best possible scientific advice at high levels in connexion with all policy decisions relating to capital investment, industrial re-organization and controls concerned with the use of man-power and materials; and (4) an increase both absolute and relative in the number of scientific workers and technologists in all industries and accordingly the most rapid possible expansion of the facilities for their education in the universities, technical colleges and other educational establishments by the provision of sufficient money and materials and by steps to improve the supply of science teachers for the schools.

As a result of further meetings of the Colonial Sub-Committee, a memorandum dealing with questions relating to education, agriculture and fisheries, health, forestry and the future of the Colonial Development and Welfare Fund was prepared, and approved by the General Committee on December 16. In connexion with the last-named Fund, the memorandum included the following statement.

"All plans for the effective application of science and technology in the Colonial territories depend to a large extent on the availability of funds from this source, and as most of these plans are inevitably of a long-term nature it appears desirable that the funds should not only be increased in volume but that arrangements should be made for sufficient monies from them to be available for several decades ahead. This is particularly important so far as assistance to Colonial education is concerned. Our review of the evidence which we have heard leads us to the conclusion that progress towards the better application of science and technology in Colonial territories depends primarily on opportunities for elementary education being widely extended. Until education is so broadly based that the vast majority of the indigenous population has become literate there will be no chance of obtaining technically trained field workers in sufficient numbers; nor will such field workers as do exist be able to obtain from villagers and peasantry that degree of intelligent co-operation without which theory, however sound, can never be translated into practice.

---

* Annual Report of the Parliamentary and Scientific Committee. Pp. 24. (31 Palace Street, London, S.W.1.)

"It appears unquestionable that the successful development of the Colonial Empire depends chiefly on the more efficient application of modern scientific knowledge and methods in such fields as agriculture, forestry, medicine or veterinary science and in other activities connected with the development of natural resources. But such efficient application depends in its turn very largely upon the technical competence of the indigenous populations and their ability to take an active part in the process."

---

# BUDGETS OF THE SCIENTIFIC DEPARTMENTS OF THE UNIVERSITY OF CAMBRIDGE

By Sir LAWRENCE BRAGG, O.B.E., F.R.S.

AN analysis has recently been made of the recurrent annual expenditure for seventeen scientific departments in the University of Cambridge. A brief summary of the figures is given below, as they may be of general interest. I am much indebted to the University treasurer, Dr. H. M. Taylor, for providing me with the material and assisting me in preparing this summary. The figures relate to the financial year 1950–51.

Some explanation of the basis of the analysis is necessary. For some years an analysis has been made of the expenditure in the Cavendish Laboratory, and a reasonable allocation of the budget between research and teaching shows that one research worker costs as much as ten full-time undergraduates. In arriving at this figure it is reckoned that the time of the staff is divided equally between teaching and research, and other items, such as assistants' wages, materials and apparatus, are allowed for. The 'cost per effective research worker' is arrived at by adding to the number of staff, holders of research fellowships and scholarships and Ph.D. students, one-tenth the number of full-time undergraduates (due allowance being made when undergraduates only get a part of their teaching in the Laboratory), and dividing the total itemized costs by the total number so obtained. In the Cavendish Laboratory, for example, an estimated cost of £755 per 'effective research worker' implies a cost of £75 a year for an undergraduate student. It must be remembered that the last figure only represents the University's contribution to his teaching, a very substantial part of which is provided by his College.

The expenditure includes the contributions to research made by outside bodies such as the Department of Scientific and Industrial Research and other government bodies, and by industry; in other words, the complete budget of each department. The capital cost of buildings and of large items of equipment such as the cyclotron is not included; but the recurrent expenditure of maintenance and of providing assistants to run apparatus has been taken into account. A proportionate share of the cost of the central administration and of the services of the Buildings Syndicate is added to the budget of each department.

For the scientific departments as a whole the staff and students are made up of: graduate staff, 340; research students, 561; undergraduates, 2,870; research assistants, 80; and assistant staff, 745. The volume of the buildings is 12·797 million cu. ft., the volume per 'effective research worker' being 15,000 cu. ft. The current expenditure during the financial year 1950–51 for the scientific departments is as follows:

| | Totals | Per effective research worker |
|---|---|---|
| Administration | £82,244 | £69 |
| Teaching and research salaries | 411,266 | 346 |
| Assistant staff wages | 156,095 | 131 |
| Supplies | 149,386 | 125 |
| Heat, light, water* | 32,185 | 27 |
| Repairs and maintenance* | 49,673 | 42 |
| Totals | £880,849 | £740 |

* The annual cost of heat, light and water per thousand cubic feet is £2·5, and that of repairs and maintenance £3·9

When a research student is admitted to one of the Cambridge laboratories, he is therefore in effect being given a research grant of £740 a year. This does not, of course, imply that, if an extra research worker is taken on, the budget is automatically increased by this amount, or vice versa if the number drops, since many of the charges are fixed charges which can only be altered by a general expansion or contraction of the department taking place over a long period. The figures do not include the fellowships, scholarships or maintenance allowances paid to research workers who are not on the staff. If we take these grants to be on the average £500 a year, the cost to the community of maintaining a scientific research worker at Cambridge is, in round figures, £1,250 a year.

The figures for individual departments vary considerably, but most lie in the range £600–900 a year. The costs of physics and chemistry, which are the largest scientific departments, are very close to the average value. For the Cavendish Laboratory the staff and students are made up of: graduate staff, 32; research students, 117; undergraduates, 544; and assistant staff, 88 (including research assistants). The expenditure for the Cavendish Laboratory is as follows:

| | Total cost | Cost per research worker |
|---|---|---|
| Administration: | | |
| Departmental £5,506 | | |
| Central £6,600 | £12,106 | £70 |
| Salaries | 44,752 | 257 |
| Wages | 25,694 | 148 |
| Supplies | 33,419 | 192 |
| Heat, light, water | 7,277 | 41 |
| Repairs and maintenance: | | |
| Departmental £4,496 | | |
| Central £3,723 | 8,219 | 47 |
| Totals | £131,467 | £755 |

As might be expected, costs for the literary faculties are considerably lower. When calculated on the same basis of one research worker being equivalent to ten undergraduates, the average figure is £416 a year as compared with £740 a year in the scientific faculties. Assistants' wages, supplies and services are expensive items in the scientific budgets.

# DEPOPULATION AND RURAL LIFE IN SCOTLAND

IN 1948, the Social Survey of the Central Office of Information was asked by the Department of Health for Scotland to carry out, in selected areas of Scotland, an investigation into rural living conditions and the causes of rural depopulation. The three areas were the Solway counties of south-west Scotland, the Tweed Basin, and north-east Scotland, within the counties of Aberdeen and Banff.

The Solway area was the subject of a detailed report. In the other two areas the results of the investigations showed that conditions there differed only slightly from those obtaining in the south-west. A cursory examination of the three sets of results revealed that, in the districts that were surveyed, the main problems of rural life remained the same, although sometimes presented with slightly different emphases. It seems possible, therefore, that the same kind of remedial measures would be applicable to all the survey areas. On the other hand, the analyses of the results from the Solway survey left in doubt the fundamental factors that had caused the decline of the population of the area. An attempt has therefore been made to isolate these factors with the aid of material from the Tweed and the Aberdeen inquiries, together with the results of a postal questionnaire sent to persons known to have migrated in the preceding twenty years[*].

A summary of the major findings showed that, in the rural areas studied, a tenth of the adult population said they would prefer to move away; but the proportion varied from county to county. Wigtownshire and Peeblesshire showed a rather higher proportion of potential migrants (those counties being more isolated and less well served with modern amenities than others), while in the better-served counties of Selkirk and Berwick the proportion was somewhat lower than the average. Only a small minority (17 per cent) of the potential migrants had actually made plans to move within a year of the date of interview, giving an average of 1·7 per cent of the adult population of the survey areas whose desire to move had reached the stage of action. People related to earlier migrants tended to become potential migrants themselves slightly more often than people who were not so related. They were also rather more conscious of the advantage of urban forms of life.

Analysis showed that national and local government, the building industry and the personal service industries produced a rather higher than average proportion of potential migrants. In contrast, there was a significantly smaller proportion of potential migrants from among those employed in agriculture, and from people who were retired or had no occupation. On the other hand, the desire to migrate was most frequently found among professional workers, clerical workers and the managerial and executive grades. The supervisory and skilled operative grades produced a smaller than average proportion of potential migrants. Within agriculture, farmers, bailiffs and foremen showed the smallest proportion of potential migrants of all occupations.

The desire to move was expressed rather more often by the young and the single people than by the old and the married. Thus, while of the general population of the survey areas 20 per cent were under thirty years of age, among the potentially migrant group 37 per cent were of this age.

The situation of the informant's dwelling had only a small degree of association with his desire to move or to remain. Thus, people living in an isolated house, or in a house situated in a small lonely group, were less likely to wish to move away than people living in the burghs. Similarly, people whose houses had no road access were less likely to wish to move than people living on main and other metalled roads. There was a greater degree of association, however, between the informant's subjective estimate of the convenience of the location of his home and the desire to move. Nearly three times as many people who said their homes were situated inconveniently as of those who thought them conveniently located said they wished to move to a town. The majority of houses thought 'inconveniently' placed, however, were in burghs or villages. An analysis of some of the actual conditions of housing and amenity in the survey areas showed that the households of potential migrants were, slightly more often than the average, enjoying a main water supply and main drainage, and were more often provided with gas, electricity, telephone and refuse collection services.

Visits to burghs were rather more frequent among potential migrants than among other people. The reasons for their visits laid a rather greater emphasis upon social calls and entertainments than upon business and marketing, compared with the rest of the rural population.

The reasons which potential migrants gave for their preference appeared to fall into the following major categories: the desire for a better job; the desire to escape rural loneliness and stagnation; the wish for change and new experience; and miscellaneous answers of which a considerable proportion referred to factors such as marriage, transfer by employer, and personal family reasons. Replies to a postal questionnaire showed that migrants had made a considerable advance in occupational skill and position after leaving rural areas. As many as 50 per cent of past migrants said they would not have moved away from the countryside had a better choice of jobs been available there.

From these findings it is difficult to point without hesitation to any single factor which has led to the process of depopulation. The explanations given by past and potential migrants for their wish to migrate offer the most solid indications as to the causes of rural depopulation. Both in the past and to-day the desire for occupational advance appears to have been the most frequent cause of migration, while evidence suggests that migration has, in fact, been accompanied by a rise in occupational status. Secondly, there was a desire to escape from the stagnation and solitude of rural life, a desire for new experience and the more vivid social life of the towns. Thirdly, there was the migration brought about by rural–urban intermarriage (probably accelerated by the War) resulting in homes being set up in the towns where the husband or wife was already living. Fourthly, some moved or wished to move for a number of circumstantial reasons, such as ill-health, family reasons, transfer by employer, and so on. Finally, there was a miscellaneous group of reasons such as bad climate in the rural areas, or children's education.

[*] Depopulation and Rural Life in the Solway Counties. By Bertram Hutchinson. (N.S. 120.) Pp. iv+110+25 plates. Depopulation and Rural Life in the Tweed Valley. By Bertram Hutchinson. (N.S. 120b.) Pp. ii+60. Depopulation and Rural Life in Aberdeen. By Bertram Hutchinson. (N.S. 120c.) Pp. 63. Depopulation and Rural Life in Scotland. (N.S. 120d.) Pp. ii+36. (London: Social Survey, 1949.)

These answers make little reference to the general environmental conditions of rural life, such as housing, public services, entertainments, and transport. A careful analysis of the environmental conditions of informants showed that in many respects potential migrants were no worse off than the remainder of the population, and in some ways were actually better equipped on an average. There is, in fact, a suspicion that small improvements in housing and amenities in rural areas have served to whet the appetite of those who have profited by them rather than to satisfy it. It cannot be said that material factors at any time take the centre of the stage in the examination of the causes of depopulation.

The aim, therefore, must be to make possible a satisfactory mode of life for the rural people on a standard which can be compared favourably with urban conditions. In this way any sense of inferiority among rural dwellers can be avoided, while fulfilling their need for self-respect. Such an outcome can be achieved in part by the provision of a more varied field of rural employment; but it must probably be accompanied by fundamental improvements in rural amenities. Better jobs in the country, it seems, must have their counterpart in the possibility of a standard of living that the people have come to expect.

# ABSORPTION OF POLYMYXIN BY BACTERIA

By Dr. A. V. FEW and Dr. J. H. SCHULMAN
Department of Colloid Science, Free School Lane, Cambridge

THE five members of the polymyxin group of antibiotics, *A*, *B*, *C*, *D* and *E*, have been shown to possess similar antibacterial spectra and potency[1]. Considerable evidence has accumulated[2–4] indicating that the polymyxins are rapidly bactericidal and not bacteriostatic, although in one paper[5] it was suggested that polymyxins *A* and *B* are bactericidal for small inocula and bacteriostatic for large inocula. In assay experiments, the marked dependence of the minimum lethal concentration of polymyxin upon the size of the inoculum[3,4,6,7] suggests that bacterial absorption of the antibiotic is high.

This communication describes experiments on the absorption of polymyxin *E* by washed suspensions of several Gram-negative and -positive bacteria. The release of soluble cell constituents, initiated by the presence of the antibiotic, and possessing an absorption maximum in their ultra-violet spectra at 260 mμ, has been followed concurrently. Free purines and pyrimidines contribute to this maximum[8,9]. Since microbiological assay of polymyxin is both tedious and not capable of high precision, a simple and accurate method has been developed based upon the observation[10] that the polymyxins form stable unimolecular films at the air/water interface when spread upon 70 per cent (w/w) ammonium sulphate solution. Fig. 1 shows the force/area curves for polymyxin *A*, *B*, *D* and *E* obtained using a standard Langmuir–Adam surface balance. Full details of the properties of these films and estimations of the molecular weights of the antibiotics have been described elsewhere[10]. To determine the concentration of polymyxin in aqueous or buffered solution, an aliquot is spread upon the ammonium sulphate solution, and the area at a surface pressure of 16 dynes/cm. (where compressibility is at a minimum) is compared with that of the standard force/area curve of the particular polymyxin at the same surface pressure. The concentration of the polymyxin solution then follows by proportion. The method is rapid, requires less than 0·5 ml. of solution, and can detect the polymyxins at a concentration of less than 5 μgm./ml. to ± 10 per cent and at 100 μgm./ml. to ± 1 per cent.

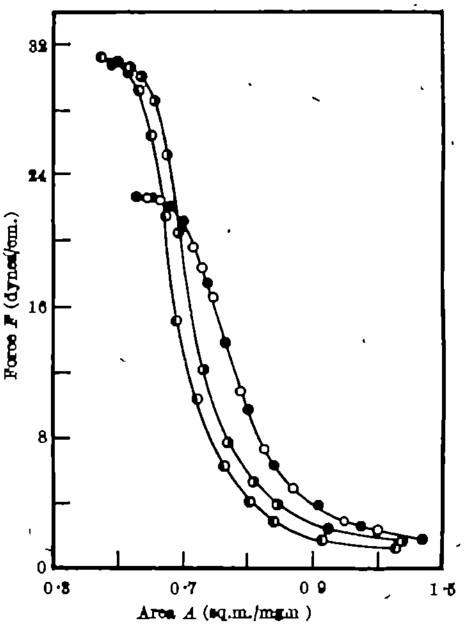

Fig. 1. Force/area curves for polymyxins *A*, ○—○—; *B*, —◐—; *D*, —●—; and *E*, —◒—, spread upon 70 per cent (w/w.) ammonium sulphate solution, *p*H 4·5, at 20° C.

For the absorption experiments the bacteria were harvested after 16 hr. growth at 37° C. and washed four times with 0·01 *M* phosphate buffer, *p*H 6·3,

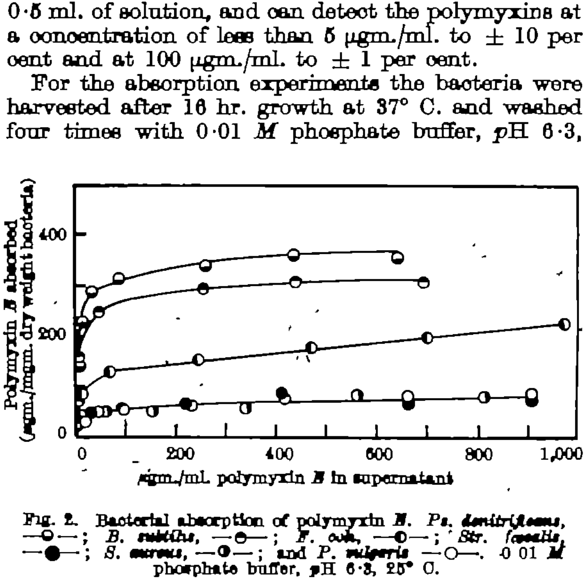

Fig. 2. Bacterial absorption of polymyxin *E*. *Ps. denitrificans*, —◒—; *B. subtilis*, —⊖—; *E. coli*, —◐—; *Str. faecalis*, —●—; *S. aureus*, —◑—; and *P. vulgaris* —○—. 0·01 *M* phosphate buffer, *p*H 6·3, 25° C.

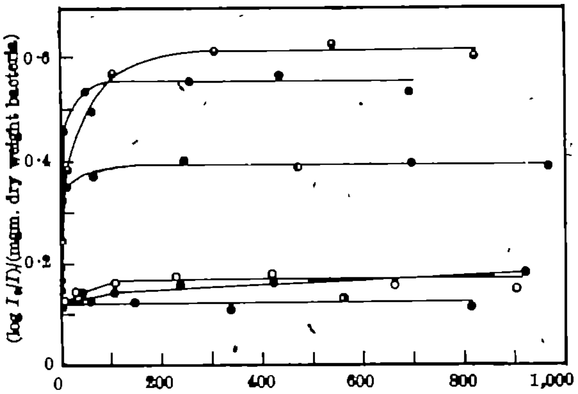

Fig. 3. Release of bacterial cellular material possessing an absorption maximum at 260 mμ. The curves are corrected for the 260-mμ absorption due to free polymyxin E. *Ps. denitrificans*, —◓—; *B. subtilis*, —○—; *E. coli*, —○—; *Str. faecalis*, —●—; *S. aureus*, —○—; and *P. vulgaris*, —○—. 0·01 *M* phosphate buffer, *p*H 6·3, 25° C.

using the centrifuge, care being taken to remove any autolysed organisms present. The bacteria were resuspended to 1 mgm./ml. dry wt. in 0·01 *M* phosphate buffer alone and buffered solutions of polymyxin *E* sulphate. 3-ml. samples were incubated for 20 min. at 25° C. The organisms were then removed by centrifugation and the supernatant solution finally cleared by recentrifuging. Aliquots of these solutions were then assayed for (*a*) residual polymyxin by the above method, and for (*b*) the presence of released cell constituents absorbing at 260 mμ, using a Unicam photoelectric spectrophotometer. The control experiments in the absence of polymyxin showed that the amount of cellular material released during the incubation period and forming an insoluble monolayer on the ammonium sulphate was very small, but where necessary was allowed for in the calculation of polymyxin absorbed. Also with certain organisms (*M. lysodeikticus* and *B. subtilis*) almost complete absorption of polymyxin was obtained at low antibiotic concentrations, giving rise to trough areas no greater than those of the control. This indicated that the cellular materials released did not form monolayers upon the salt solution and hence did not interfere in the assay method.

The polymyxin *E* absorption isotherms and released cellular material isotherms for six organisms are shown in Figs. 2 and 3. Determination of the sensitivities of the organisms by streaking 24-hr. broth cultures upon nutrient agar containing increasing quantities of polymyxin *E* showed that *Ps. denitrificans*, *B. subtilis* and *E. coli* were all inhibited by 5 μgm./ml., whereas *S. aureus*, *P. vulgaris* and *Str. faecalis* were not inhibited by 100 μgm./ml. The results indicate that more polymyxin is absorbed by the sensitive organisms than the highly resistant bacteria. The initial absorption process is complete at polymyxin concentration in the supernatant of 100–150 μgm./ml., after which further absorption is slight. Of four strains of *E. coli* investigated, three showed agglutination phenomena which were maximal at supernatant concentrations of 150 μgm./ml. Similarly, Latterade and Macheboeuf[11] have shown that the *R* form of *E. coli* is agglutinated, whereas the *S* form which contains the *O* antigen is not. Suspensions of *Ps. denitrificans* containing the antibiotic exhibit an increase in optical density also maximal at 150 μgm./ml., and may be due to formation of an insoluble complex between bacterial components and polymyxin similar to those demonstrated between polymyxin and yeast ribonucleic acid[11] and serum albumen[12,5]. Fig. 3 shows that, in the case of the highly resistant organisms, polymyxin causes no significant increase in the release of material showing absorption at 260 mμ when compared with untreated control cells. With sensitive bacteria, however, the presence of polymyxin causes a rapid release of cellular material which is complete at low concentrations of polymyxin in the supernatant. Experiments with *B. subtilis* showed that the absorption of polymyxin and release of material showing absorption at 260 mμ were rapid and unaffected by incubation times between 5 and 60 min.

It is evident that one of the effects occurring immediately after the exposure of sensitive bacteria to polymyxin is a disturbance of the osmotic properties of the organisms and consequent rapid release of cell materials. In this connexion, it has been shown that the injection of polymyxin *E* to a concentration of 0·5 μgm./ml. beneath certain oriented monolayers results in absorption and rapid penetration of the monolayer, although the depression of surface tension of a polymyxin *E* solution at this concentration would be less than 0·1 dyne/cm.

We wish to thank the Wellcome Research Laboratories for the polymyxins, Dr. E. F. Gale for certain bacteria, the Department of Pathology, Cambridge, for culture media and the Medical Research Council for a personal grant to one of us (A. V. F.).

# CHROMATOGRAPHY OF THE GROWTH SUBSTANCES IN PLANT EXTRACTS

By Prof. T. A. BENNET-CLARK, F.R.S., and
N. P. KEFFORD

King's College, London

A METHOD for the chromatographic separation of plant growth substances was described by Bennet-Clark and Tambiah at the Society of Experimental Biology conference in January 1951. Later, they published details of this method[1], which Luckwill[2] has also employed.

For the successful routine chromatography on paper of plant extracts, the original technique has been modified. The plant tissues examined have usually been seedlings, which were chosen for their possible use in subsequent growth studies, and since

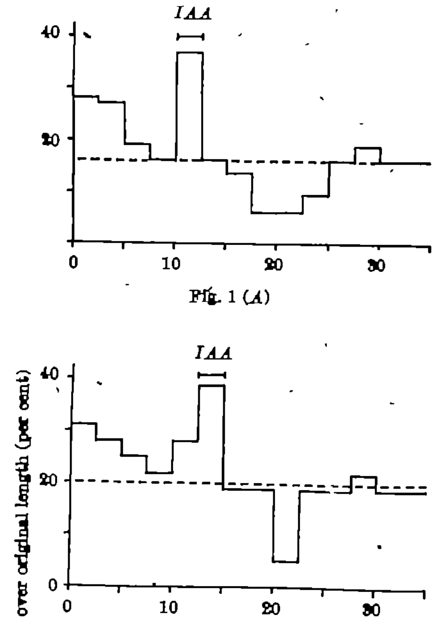

Fig. 1 (A)

Fig. 1 (B)

Activities in coleoptile extension, shown as histograms, of squares cut from chromatograms of etiolated broad bean shoot extract (1 A) and broad bean root extract (1 B). Broken lines represent the extension of controls, and the position of an indole-3-acetic acid guide-spot is marked *IAA*.

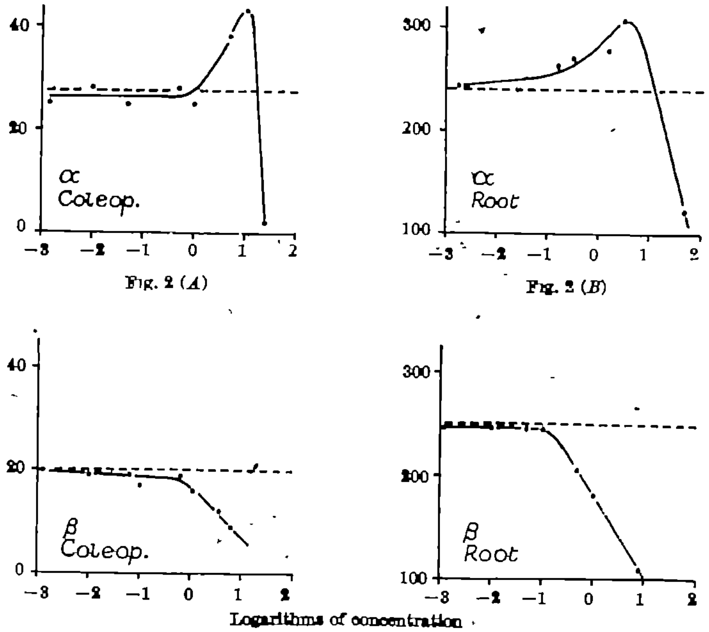

Fig. 2 (A)

Fig. 2 (B)

Fig. 2 (C)

Fig. 2 (D)

Activities in coleoptile extension (2 A) (2 C) and root extension (2 B) (2 D) of a series of concentrations of accelerator-α (2 A) (2 B) and inhibitor-β (2 C) (2 D). Unit concentration is roughly that of the hormone in the tissue (see text). Broken lines represent the extension of controls.

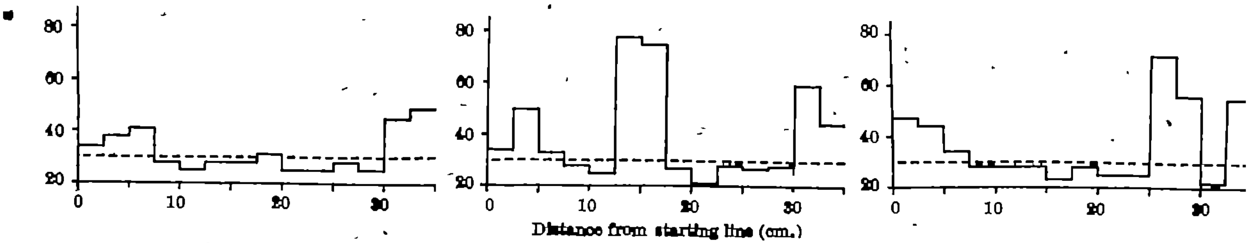

Fig. 3 (A)

Fig. 3 (B)

Fig. 3 (C)

Activities in coleoptile extension, shown as histograms, of squares cut from chromatograms of *Aegopodium podagraria* rhizome extract after rhizom had been treated with water (3 A), indole-3-acetic acid (3 B) and 2 : 4-dichlorophenoxyacetic acid (3 C). Broken lines represent the extens of controls. The 15-cm. band is due to indole-3-acetic acid, the 27·5-cm. band to 2 : 4-dichlorophenoxyacetic acid, and one 32·5-cm. band indole-3-acetonitrile

these were found to be relatively poor in growth substances (compared, for example, with many members of the Cruciferæ), considerable purification was found to be necessary before the extracts could be successfully chromatographed. In order to simplify purification, etiolated tissues were used, and then it was found that the extract fraction containing the acidic substances could be chromatographed without further purification; however, the fraction containing the neutral and alkaline substances usually would have required treatment to remove oils.

The methods used were as follows: macerated plant tissue was extracted with alcohol for twenty-four hours at − 5° C. The alcoholic extract was separated by centrifugation, concentrated under reduced pressure and the aqueous residue extracted with ether at $pH$ 3. The ether extract was treated with sodium bicarbonate solution, which was separated and then acidified and re-extracted with ether. The ether-soluble acidic substances from the plant extract, obtained in this final ether extract, were suitably concentrated and applied to the starting line of a chromatogram, as a spot or a strip, from a dropping pipette in a stream of nitrogen. The chromatograms were developed in isopropyl alcohol : water :: 10 : 1, with ammonia in the base of the tank and, parallel with the extract, guide spots of the known growth substances indole-3-acetic acid and indole-3-acetonitrile could be run and their positions detected at the conclusion of the development by spraying with a ferric chloride – perchloric acid mixture and nitrous acid – nitric acid mixture respectively.

The biological testing of developed chromatograms using subapical sections of *Avena* coleoptiles was described previously[1]. A second biological test has been used in which the section 1·5–3·0 mm. from the tip of pea (*Pisum sativum* var. The Pilot) radicles, grown in moist sawdust for four days at 22° C., were shaken at 25° C. for twenty-four hours with 2 ml. 1 per cent sucrose solution containing the growth substances, and their length extension growth measured. Since the presence of paper squares in the test liquid, as used in *Avena* coleoptile bioassay method, could interfere with the pea root bioassay method, the latter was mainly used for testing solutions of growth substances eluted from chromatograms. To obtain these eluted solutions a large amount of plant extract was applied to paper as a strip and was developed parallel with a spot of the same extract. The chromatogram developed from the spot was cut into 2·5-cm. × 2·5-cm. squares and bioassayed, thus locating the active areas; the parallel active areas were cut from the large chromatogram and eluted by boiling with alcohol and ether.

The results described below have been obtained with a variety of etiolated seedlings and roots, of which the following are examples: pea (*Pisum sativum*) shoots and roots, broad bean (*Vicia faba*) shoots and roots, sunflower (*Helianthus annuus*) shoots, maize (*Zea mays*) roots, potato tubers and shoots, and *Aegopodium* rhizomes.

On all the chromatograms of the acidic fractions of ether extracts of shoot and root material which have been bioassayed, three active areas have been clearly detected. Figs. 1 *A* and 1 *B* show the results, in the form of a histogram, of bioassays with *Avena* coleoptile sections of chromatograms of extracts of broad bean shoots and broad bean roots, respectively. The position of an indole-3-acetic acid guide spot is shown as *IAA*.

The central active area ($R_F$ = approx. 0·3) corresponds with indole-3-acetic acid, which can be detected in this position as a characteristic coloured spot when a chromatogram of an extract of plant material rich in this substance is sprayed with $Fe^{+++}$ – perchloric reagent. In addition, serial dilutions of eluates of this area, when tested for *Avena* coleoptile section extension and pea root section extension, give typical growth-concentration curves. Assuming that the active area with $R_F$ value less than that for indole-3-acetic acid, as shown in Figs. 1 *A* and 1 *B*, corresponds to one substance, the term accelerator-α is suggested for it, and if the same applies to the area with $R_F$ value greater than indole-3-acetic acid, then the term inhibitor-β is suggested for that substance. Accelerator-α and inhibitor-β have been eluted from chromatograms and serial dilutions of the eluates have been assayed for *Avena* coleoptile extension and pea root section extension; and in Fig. 2 the percentage extension of the sections over original length has been plotted against the logarithm of concentration. The concentration scale was arbitrary, normal or unity being the concentration obtained if all of the eluate were dissolved in the same number of ml. of solvent as grams of plant material were extracted to give the eluate. The shape and the position relative to the axes of the curves shown in Fig. 2 are typical of eluates obtained from several different sources. It may be noted that accelerator-α has a very considerable root-growth promoting effect in 'physiological concentrations'.

Two points of interest arose from an application of the chromatography of plant extracts to a growth study involving the rhizomes of *Aegopodium podagraria*, regarding which we possess special information[5]. Fig. 3 *A* expresses as a histogram the results of a bioassay of a chromatogram of the acidic fraction of an ether extract of these rhizomes. Accelerator-α was clearly detected together with an accelerator, not previously encountered except possibly in traces, which runs very close to the solvent front. This new accelerator has been shown by $R_F$ comparison, also by the characteristic colour reaction on spraying with nitrous – nitric acid and by similarity in growth effects of a series of dilutions, to be very probably indole-3-acetonitrile[4], which although not an acid is carried to some extent from an ether solution into sodium bicarbonate solution and back to ether on re-acidification. Although the chromatogram recorded in Fig. 3 *A* did not show it, chromatograms of larger quantities of rhizome extract indicate the presence of indole-3-acetic acid and inhibitor-β; however, from the evidence shown it is clear that the activity of the indole-3-acetonitrile in these rhizomes is greatly in excess of the activity of the indole-3-acetic acid.

The *Aegopodium* rhizomes can be fed artificially with indole-3-acetic acid or with 2 : 4-dichlorophenoxyacetic acid; each of these treatments causes a characteristic and very considerable modification of their growth-rates and geotropic response[5]. These feeding treatments caused a marked change in the chromatogram of the extract as shown in Fig. 3 *B*, which is of an extract of rhizomes grown in indole-3-acetic acid, and Fig. 3 *C*, which is of rhizomes grown in 2 : 4-dichlorophenoxyacetic acid. Indole-3-acetic acid clearly entered the rhizomes, considerably increasing their normal content, and 2 : 4-dichlorophenoxyacetic acid, which runs on the chromatogram at an $R_F$ value between those for inhibitor-β and indole-3-acetonitrile, also entered in quantity. Neither treatment produced any obvious change in the concentration of accelerator-α, inhibitor-β or indole-3-acetonitrile.

Of particular interest is the occurrence in *Aegopodium podagraria* rhizomes of indole-3-acetonitrile, which previously has been reported only in members of the Cruciferæ. Activity due almost certainly to the nitrile has also been found in chromatograms from potato tuber extracts and has been identified by spraying with nitrous – nitric acid and biological assay.

Since activity in the region 27·5–30 cm. due to indole-3-acetonitrile has been detected clearly in *Aegopodium* and potato, it now appears possible that the small humps shown in this region in Figs. 1 *A* and 1 *B* (bean) are also due to nitrile. Such activity has not always been noticed; but this may be due to its being obscured by impurities running near the solvent front and the fact that the biological testing of the region near the solvent front was often omitted in our earlier assays.

Obviously, investigations under conditions of chromatography favourable to the running of indole-3-acetonitrile should be carried out on the fraction of plant extracts containing the neutral substances where the bulk of the nitrile should be located. Of interest also is the detection and possibility of estimation of the synthetic growth substance 2 : 4-dichlorophenoxyacetic acid in a plant extract.

Without going into detail which will be published *in extenso* elsewhere, it may be stated that all shoot and root materials studied have contained hormones α and β and indole-3-acetic acid. We have no information at present on the nature of either α or β; however, one cannot dismiss the possibility that α is auxin-*a*, the real existence of which is often doubted. No active substance of $R_F$ similar to accelerator-α has yet been detected on chromatograms of extracts of urines of various origins. [Dec. 16.

## Use of Tracers in Chemical Dosimetry

The action of X-rays and gamma-rays on a solution of ferrous sulphate in 0·8 *N* sulphuric acid has been studied by a number of investigators[1]. The iron is oxidized to the trivalent state, and the amount of trivalent iron is proportional to the radiation dosage. For this reason the ferrous sulphate solution has been used for radiation dosimetry. The amount of ferric ion is usually measured colorimetrically, photometrically or volumetrically. In the present investigation, some experiments have been carried out to measure the ferric ions radiometrically in order to increase the sensitivity of the dosimeter.

Ferrous ammonium sulphate was dissolved in redistilled water and acidified with sulphuric acid, and iron-59 was added to the solution as a tracer. This solution was irradiated with gamma-rays from a cobalt-60 source. After irradiation, the ferric ions formed were separated from ferrous ions by extraction of the ferric thiocyanate with *iso*amyl alcohol. The activity of the organic phase and of the water phase was then determined with a liquid Geiger–Müller counter tube. From these measurements one obtains the percentage of ferric ions in the irradiated solution.

The radioactive isotope iron-59 used as a tracer in this experiment was made with the Werner synchro-cyclotron by bombardment of copper with 185-MeV. protons. The iron formed was separated by extraction with *iso*propyl ether.

The measurements can easily be carried out with an accuracy of more than 2 per cent. By changing the concentration of the ferrous ammonium sulphate in the solution, one obtains different dosage ranges. It seems possible, for example, to measure the radiation dosage in the range 0–100 r. with an accuracy of ± 2 r. The sensitivity can probably be increased still more. The amount of tracer used must not be so large that it gives a radiation dosage which cannot be neglected in comparison with the dosage to be measured.

Experiments have also been carried out to investigate the suitability of an acid or neutral solution of potassium iodide for chemical dosimetry. The action of ionizing radiation on solutions of potassium iodide has been studied by Lefort[2]. In the present experiments the radioactive isotope iodine-131 was added as a tracer to a neutral, hydrochloric or sulphuric acid solution of potassium iodide, which was then irradiated with cobalt-60 gamma-rays. After the irradiation, the solution was extracted with carbon disulphide and the activity of the organic phase and of the water phase was determined as before.

At the beginning of the irradiation, the iodide is oxidized to iodine in an amount proportional to the radiation dosage. However, a state of equilibrium is soon reached because the radiation also reduces the iodine. This state of equilibrium is reached at 25 per cent iodine for a neutral solution, at 60–70 per cent iodine for a *N* hydrochloric acid solution and at about 35 per cent iodine for a sulphuric acid solution of *p*H 2. The number of iodide ions oxidized by a certain dosage of radiation is considerably lower than the corresponding number of ferrous ions in a ferrous sulphate solution. For this reason one has to use very dilute iodide solutions to get a dosimeter of high sensitivity. However, these dilute solutions do not seem to be stable enough to be useful as dosimeters.

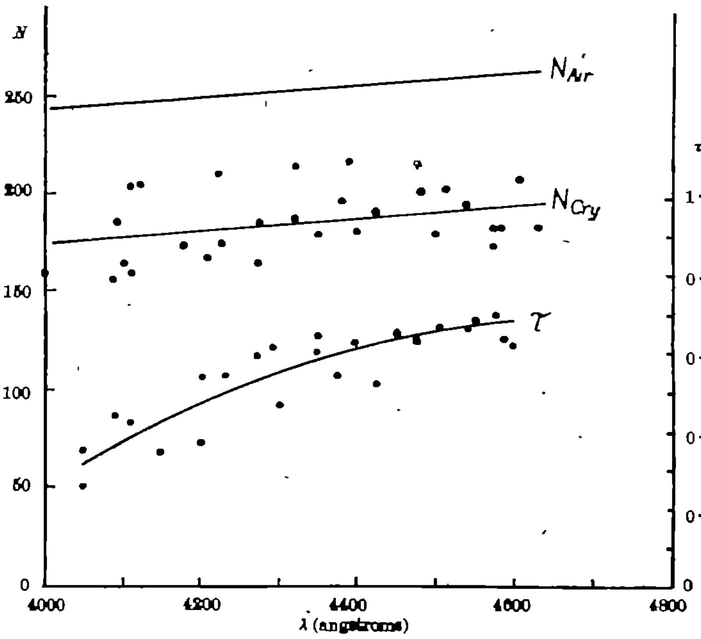
## Multi-layer Dielectric Reflecting Films at Wave-lengths between 4000 and 4600 A.

Recent correspondence[1,2] has directed attention to the lack of information about the efficiency of multi-layer dielectric reflecting coatings at wave-lengths shorter than 5200 A.; this prevents an assessment of the relative merits of dielectric and silver films as coatings for Fabry–Perot interferometer plates at these wave-lengths. To this end, multi-layer dielectric interference filters have been prepared, and their characteristics measured over the wave-length range 4000–4600 A.

Each filter was deposited on glass, and consisted of two reflecting films, both of seven λ/4 layers (four zinc sulphide and three cryolite), separated by a λ/2 spacing layer of cryolite, thus giving a first-order



pass-band at wave-length λ. By suitably orienting the glass support in the evaporation chamber, each layer was deposited in the form of a wedge such that λ varied over the filter between 4000 A. and 4600 A. In this way the pass-band at each point of the filter was made to centre on the wave-length for which the reflectivity of the seven-layer films was a maximum.

The half-intensity width and peak transmission of four such filters have been measured for several wave-lengths in the above range by scanning the pass-band, dispersed by a large glass spectrograph, using a multiplier photo-cell in conjunction with an amplifier and recorder. The results obtained are shown in the accompanying graph. *N* (middle curve) is the ratio of the wave-length of the pass-band to its half-width, and is the "effective number of interfering beams"[3], and $\tau$ is the fraction of the incident light transmitted at the peak of the pass-band. From these measurements the geometric mean values of the reflexion, transmission and absorption coefficients for the pair of films in each filter can be calculated, and values for three wave-lengths are shown in the accompanying table.

| λ | 4100 A. | 4300 A. | 4500 A. |
|---|---|---|---|
| Reflexion coefficient | 0·982 | 0·983 | 0·983 |
| Transmission coefficient | 0·011 | 0·012 | 0·014 |
| Absorption coefficient | 0·007 | 0·005 | 0·003 |

These values refer to the system cryolite/7-layer film/glass and would be altered if the spacing layer were air. Theory indicates that the reflexion coefficients would be increased by about 0·005 for the system air/7-layer film/glass, while the ratio of transmission to absorption remains constant. Values of *N* embodying this correction are shown in the upper curve of the graph.

A comparison of silver and dielectric films as Fabry–Perot interferometer coatings may now be made by comparing values of *N* for a given $\tau$, since *N* is directly proportional to the attainable resolution assuming perfectly flat plates. For $\tau = 0·45$ at λ 4200 A., new and aged silver films give $N = 16$ and 11, respectively[4], whereas for seven-layer dielectric films *N* is about 250. The theoretical resolution at this wave-length using dielectric films is thus fifteen to twenty times that obtained with silver films. In practice, of course, the resolution is limited by imperfections in the interferometer plates; but whereas silver films do not allow full advantage to be taken of good-quality flats, dielectric coatings are evidently more than adequate.

The performance of interference filters is not subject to this limitation, since irregularities of the glass support are of no account, and full use may be made of the superiority of dielectric coatings. For example, at λ 4600 A. a pair of seven-layer coatings separated by a first-order spacer gives a half-width of 22 A. and a peak transmission of 70 per cent, whereas a first-order silver interference filter might have a half-width of 150 A. and a transmission of 40 per cent[5]. Theoretically, a higher-order spacer would give an even narrower pass-band, but roughness in the spacing layer appears to limit what can be achieved by this means[6]. Improvement, however, is possible by increasing the number of dielectric layers, and a preliminary experiment with a pair of nine-layer coatings separated by a first-order spacer has resulted in a half-width of 15 A. and a peak transmission of 60 per cent at λ 4700 A.

We are grateful to Mr. J. E. Geake for the loan of the amplifier and recorder.

## The Sunspot Number Series

Sunspot numbers form a quasi-periodic series (see Fig. 1, upper curve) going back for eighteen cycles to 1750. Very numerous attempts have been made to analyse the series, with little success. It does not appear to contain a truly periodic term, as do tides and weather records. The fundamental Fourier component, as determined over a particular section of the series, yields only a poor estimate of the next cycle, both in duration and in phase. Very little regularity of any kind has been found.

The objects of analysis have been twofold: to discover a process which would yield a time series resembling the sunspot series, and to predict the future of the series, which incidentally would be very valuable in relation to telecommunications. No suggested process has been substantiated and predictions are made on an empirical basis. The range and accuracy of forecasting would presumably be improved if some hypothesis could be found which would give rise to series resembling the sunspot series.

The present communication presents an idea which could lead to such a hypothesis. According to Hale's well-known discovery, based on observations of the magnetic polarities of sunspots, the sunspot cycle lasts twenty-two, not eleven, years. The upper curve of Fig. 1 does not include this information; but as there is no known difference in the terrestrial effects between successive eleven-year cycles, its

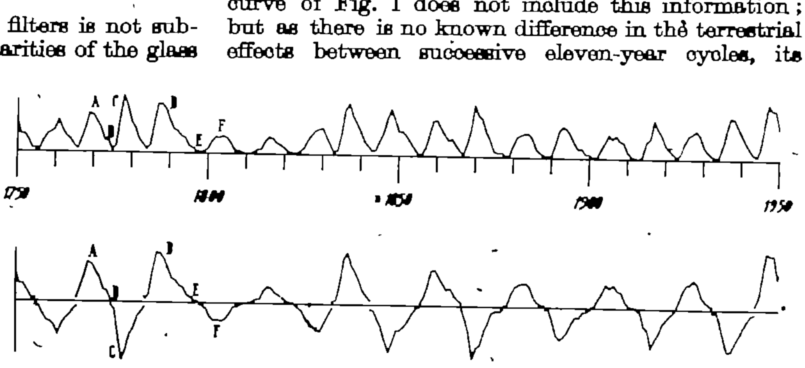

Fig. 1. (Above). Sunspot number series, 1750–1950
(Below). The same series, but showing alternate 11-year cycles reversed in sign

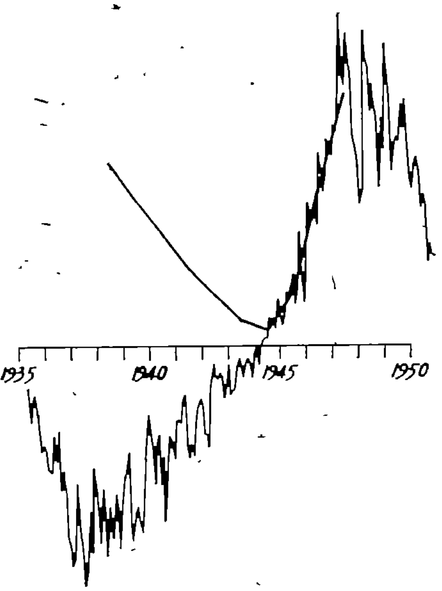

Fig. 2. Monthly means (—) and annual means (—) about the sunspot minimum of 1944

appropriateness has not hitherto been questioned. It is now proposed to plot alternate cycles, positive and negative, as in the lower curve of Fig. 1.

It may be objected that, in years of minimum spots, the sunspot number has not always been zero, whereas the alternating representation requires accurate zeros. In the years 1766, 1784, 1843 and 1944, the minima were very noticeably different from zero. This objection can be met with the aid of Fig. 2, in which the minimum of 1944 is shown in greater detail, by monthly means in addition to annual means. It is clear that the sunspot number actually passed through a very good zero in 1944, but that the taking of annual means obscured this fact. Any further difficulty vanishes when it is remembered that spots belonging to successive cycles are to be taken with opposite signs, and that it is possible to identify which cycle a spot belongs to by taking into account its latitude and magnetic polarity. In plotting Fig. 1 (lower), no attempt has been made to correct the minimum sunspot numbers.

The two curves of Fig. 1 look at least equally regular. In particular, the lower curve does not exhibit obvious discontinuities at the zeros, apart from the gaps due to the above-mentioned deviations of the minima from zero. It has attractive features, such as symmetry about its mean value, and a mean value which is practically zero (less than 1 per cent of mean maximum).

A hypothesis of Yule's[1] likens the sunspot series to the motion of a swinging pendulum which boys are pelting with peas, sometimes from one side and sometimes from the other. After lengthy analysis, Yule concluded that further work on this line seemed to be blocked. Yule, however, began by subtracting the mean value from the series. The series was thus asymmetrically distributed about its zero, and the maximum excursions in the negative direction were all practically equal. It is therefore perhaps not surprising that the stipulated mechanism failed. The present idea re-opens this promising line of investigation.

If the new presentation is significant, a correlation might be expected between the fall of one cycle to zero and the rise of the following cycle, that is, a steep rise might be expected to follow a steep fall to zero. It is found that the correlation coefficient between the average rate of fall from maximum to minimum and the average rate of rise from the minimum to the next maximum is 0·57. In comparison, if the rate of rise is correlated with the rate of fall of the following cycle and the preceding cycle but one, the values are − 0·03 and − 0·001 respectively. As particular examples of this correlation, the steep fall *AB* was followed by the steep beginning *BC*, and the gradual fall *DE* was followed by the gradual beginning *EF*.

The idea of representing the sunspot series as a twenty-two-year oscillation with zero mean value is offered to mathematicians, physicists and engineers sharing a common interest in sunspots. Some past attempts to analyse the sunspot number series may well have been near the truth, but may have foundered on the eleven-year version of the upper curve of Fig. 1.

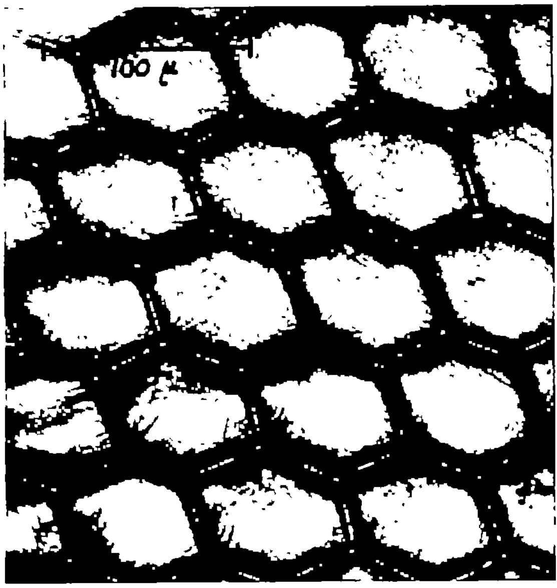
## A Special Kind of Growth Structure in Metal Single Crystals

The purpose of this communication is to describe and illustrate the growth of single zinc crystals, using a method in which the growth boundaries are examined, without etching, in their natural relief by means of a stereomicroscope.

The crystals are produced by a somewhat modified Czochralski–Gomperz method, in which the diameter of the single crystal wires is held at about 0·5 cm. If now the crystal wire is suddenly removed from the surface of the melt out of which it is growing, one gets as the termination of the wire a section which is more or less convex according to the temperature gradients prevailing in the region of growth, and which consists of small polygonal units, themselves individually convex.

In the case of zinc, under favourable conditions, remarkably regular hexagons are obtained, as may be seen in the accompanying photograph, which represents the appearance of part of such a termination grown under a steep temperature gradient. The zinc used had a purity of 99·99 per cent, the rate of withdrawal or growth was 30 cm./hr., and the hexagonal crystallographic axis was, in this case, inclined approximately 25° to the axis of the wire. Inside the hexagons there are small raised spots, sometimes only single, which are probably due to traces of dendrites growing out from the interface into the melt. Also there are, running across the whole section, parallel straight lines, traces of 0001 planes, not produced by later plastic deformation. Corresponding to the growth structure at the termination, there is also visible on the outer surface a structure which looks as if the wire had grown in parallel hexagonal strands, with their axes making a small angle (a few degrees) to the axis of the wire.



The growth structure obtained by the above method obviously bears a close relation to the structures which Buerger[1] has obtained by etching with strong hydrochloric acid the cleavage and outer surfaces of zinc single crystals grown by the Bridgman method. The method described here has been successfully extended to other metals; a fuller account of the results will be published elsewhere.

## Gloss of Papers

WE have completed a psycho-physical study of the gloss of several series of coated and uncoated papers differing widely in surface finish and in colour, ncluding a black, a green and a mauve, besides an assortment of shades of white, cream, yellow and brown.

Over such a wide range considerable disagreement s found between judgments of individual observers, and marked shifts in ranking occur when the conditions of illuminating and viewing the specimens are changed. Judgment appears to be based upon an appraisal of a physical situation taken as a whole. The factors of this physical situation are weighted differently by different observers under the same conditions and by the same observer under different conditions. Consequently it is possible only to devise a method of instrumental grading which shall satisfy the mean judgment of a large number of observers under certain average conditions of grading. Within these limitations, an extension of an empirical equation previously suggested[1] enables instrumental measurements to be fitted to visual gradings tolerably well. The general expression is:

$$G = AS(a+b \tanh 10/bL) - B \tanh [cS(P-1)/100]^2,$$

and is applied to papers illuminated by a nearly parallel beam incident at 45°, where $S$ is the intensity of light reflected at the specular angle (45°), $L$ the ntensity in the direction of the normal (0°) and $P$ is defined as the ratio of intensity at 45° to that at 40°. $A$, $a$, $B$, $b$ and $c$ are constants and $G$ is the numerical estimate of the visual gloss. All intensities are expressed as a percentage of the intensity reflected normally to a surface of magnesium oxide under the same incident beam.

It is seen that the equation represents a weighted mean of three factors. The first is $S$, the intensity at the specular angle. For papers of high luminance factor and moderate gloss, this factor predominates. The second is ($S \tanh 10/bL$) and provides a measure of the contrast observed when the eye is transferred from the specular angle to a direction remote from the specular angle: the hyperbolic tangent has no physical significance but is introduced in order to prevent $G$ from rising to abnormally high values for black and dark grey papers. The third term, $\tanh [cS(P-1)/100]^2$, is appreciable only for papers at the higher end of the gloss scale. For highly glossy papers having the same values of $S$ and $L$, the one having the more sharply peaked polar curve is adjudged the less glossy by most observers, and the third term of the equation makes allowance for this.

It appears that in order to get the best possible correlation between $G$ and visual observations, the weighting constants $A$, $a$, $B$, $b$ and $c$ must be adjusted to suit the individual observer and the prevailing conditions of observation. This is generally impracticable and undesirable, and for most purposes we find that the equation reduced to the form:

$$G = S(0{\cdot}390+0{\cdot}325 \tanh 20/L) - 100 \tanh [0{\cdot}115\ S(P-1)/100]^2$$

gives with visual observations product-moment and rank correlation coefficients of the order of +0·94 for all types of paper, and it is suggested that it may be made the basis of a practical method of gloss specification. For comparative work with similar papers where $P$ is small and $L$ nearly constant, the equation can, of course, be simplified. The incident and reflected beams used in this work were in the form of truncated wedges of vertical angle 0° 30′.

Our thanks are due to Prof. B. Steenberg of Svenska Träforskningsinstitutet, Stockholm, for supplying some of the papers, together with the visual gradings of 476 Swedish observers. A detailed account of this work is being prepared for publication elsewhere.

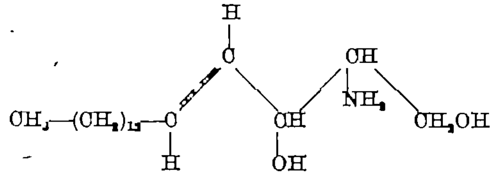
## Trans-Ethylenic Structure of Sphingosin

THE molecular structure of sphingosin (I) has been established with reasonable certainty by degradation[1] and by the synthesis of the dihydro derivative[2]. Concerning the spatial structure, however, no more can be inferred at present from the available data of optical rotations than that the compound would seem to belong to the D-(−)amino carboxylic acid series[3].

An attempt was made by Ono[4] to decide on the steric disposition of the substituents of the ethylenic double bond by conversion of the compound with lead tetra-acetate into hexadecenal, and hence to the corresponding hexadecenoic acid to which the author assigns the *trans* structure. Unfortunately, no experimental details of the selective oxidation of (I) are given, or the melting point of the 2-hexadecenal obtained and of the other geometrical isomer of hexadecenoic acid, or the principle used for establishing the configurations.

The investigation of the configurational correlation[5] of (I) to the four theoretically possible threoninol isomers is expected to disclose the configuration of both asymmetric centres in (I). The work being in progress at our laboratory, at present we offer the evidence on the spatial structure of the olefinic chain in (I).



(I)

Carter[6] has stated without further comment that triacetyl dihydrosphingosin melts at almost the same temperature as does triacetyl sphingosin, and the mixture of the two substances shows very little melting point depression. Now, according to the syncrystallization rule of Bruni[7], only the more stable of a pair of geometrically isomeric ethylenes would form mixed crystals with the corresponding dihydro derivative. Since the skeleton of the long aliphatic chain of dihydrosphingosin can have only the staggered orientation, sphingosin cannot be expected to enter the crystal lattice of the former unless it represents the *trans* form of the ethylene bond. Actually, we find that neither the triacetyl nor the tribenzoyl derivative gives a depression of melting point with the corresponding triacyl dihydrosphingosin, the observed values taken with mixtures of various proportions indicating strongly the formation of solid solutions ('mixed crystals') as evidenced by the accompanying photographs and graph. This suggests with a very high degree of probability that sphingosin has the *trans* ethylenic structure, which would seem to be well in line with the known stability of the compound toward heating and toward alkalis[8].

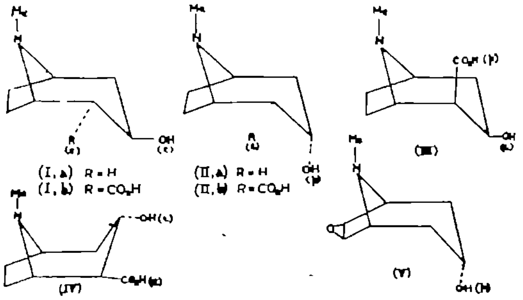
## Conformation of Tropane Alkaloids

It has become generally accepted that *cyclo*hexane compounds[1] and pyranosides[2] possess the chair conformation. By analogy we may assume that piperidine and its derivatives also exist in the chair conformation. Starting from this assumption, it is possible to determine the conformation of tropane alkaloids.

The sodium and alcohol reduction of tropinone leads mainly to ψ-tropine. This method of reduction of a ketone is known to afford an equatorial hydroxy substituent[3]. The hydroxy group in ψ-tropine should, therefore, be in the equatorial position and (I)*a* and (II)*a* should represent the conformation of ψ-tropine and tropine, respectively. The fact that tropine can be epimerized to ψ-tropine by the action of sodium amylate supports this view. Similar reasoning indicates an equatorial position for the hydroxy group in ψ-ecgonine. This conformation is in keeping with the observation that ecgonine, which should have the hydroxy group in the polar position, is more readily dehydrated than ψ-ecgonine.

The reduction of methyl tropinone-2-carboxylate leads to the methyl ester of *dl*-ψ-ecgonine, *dl*-ecgonine and a 'third racemate'—the first-named reduction product being obtained in a preponderant amount. Thus, ψ-ecgonine is the most stable of the four epimers possible for 2-carboxy-3-hydroxy-tropane. Both the hydroxy and the carboxy groups in the unknown epimer should therefore be assigned polar positions, whereas in ψ-ecgonine both these substituents should be equatorial. The conformation of ψ-ecgonine, ecgonine and the 'third racemate' can now be represented by (I*b*), (II*b*) and (III), respectively.



Fodor[4] has deduced the configuration of tropane alkaloids by an elegant investigation and shown that in ψ-ecgonine the hydroxy group is *syn* with respect to the nitrogen and *trans* with respect to the carboxyl group. The conformation (I*b*) is in accord with this configuration. If, however, instead of the chair conformation we assign the boat conformation to the piperidine ring, ψ-ecgonine will be represented by (IV) and the hydroxy will be *anti*-placed with respect to the nitrogen and will therefore be at variance with Fodor's findings.

In view of the ready conversion of scopine to scopolamine—a tetrahydrofuran derivative—the only reasonable conformation for scopine is (V), in which the piperidine ring is in the chair form[4]. This may be counted as indirect evidence in favour of the chair conformation of the piperidine ring in (I) and (II). The conformation of atropine, cocaine and other related alkaloids follows from (I) and (II). It is interesting to note that all the tropane alkaloids possessing mydriatic or anæsthetic properties have the ester group (in position 3) in the polar position.

## Organic Anion Binding by Denatured Bovine Serum Albumin

IN the course of investigations in progress in this laboratory on the binding of acidic phosphatides by bovine serum albumin, certain deviations from the commonly accepted properties of denatured bovine albumin prompted a closer study of the binding of an organic anion (methyl orange) by bovine albumin denatured with urea and guanidine hydrochloride. The view that bovine albumin loses its high affinity for methyl orange after denaturation seems to have arisen mainly from experiments employing heat as the denaturing agent[1]. Yet the persistence of high affinity for the dye has been used as evidence for the maintenance of the native state of bovine albumin[2].

It is to be expected that heat denaturation, especially if allowed to result in coagulation of the protein, would tend to decrease the binding power because of the formation of new intermolecular salt bridges and hydrogen bonds between adjacent uncoiled peptide chains. If, however, denaturation is restricted to changes in the spatial relationships of individual molecules with minimal secondary intermolecular associations, as in partial or complete uncoiling of a globular protein, the binding power should increase, since previously 'buried' binding sites would become available in the process. This appears to be true for the heat denaturation of egg-albumin[3]. If one considers the empirically derived binding index of Klotz[4], denaturation *per se*, without secondary aggregation, association and salt-bridge formation between molecules, should produce either no change or an increased binding affinity, as $\Sigma(\equiv NH^+)/\,|\,\Sigma(-OH)-\Sigma(-COO^-)\,|$ already probably represents a minimum value in the native state.

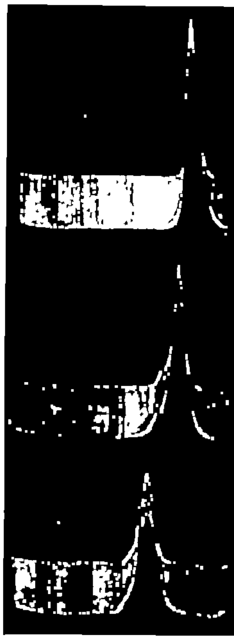
The binding properties of denatured bovine serum albumin have been investigated by comparing the effects of urea and guanidine hydrochloride denaturation on the binding of methyl orange after removal of the denaturing agents. Parallel experiments on bovine albumin denatured with urea and with guanidine hydrochloride were carried out.

The protein preparations used in these experiments consisted of purified bovine plasma albumin (given by Dr. Walter L. Hughes, jun., Laboratory of Physical Chemistry Related to Medicine and Public Health, Harvard University) and Armour crystalline bovine serum albumin. The latter proved to be electrophoretically pure and also homogeneous by sedimentation analysis in the Spinco analytical ultracentrifuge. The methyl orange was a reagent-grade product of the Allied Chemical and Dye Corporation (National Aniline Division).

The bovine serum albumin was mixed with appropriate amounts of powdered urea and guanidine hydrochloride in the dry state and denatured by the addition of water to produce a 40 per cent solution with respect to urea and an 8-*M* solution with respect to guanidine hydrochloride. The denaturing agents were rapidly removed by exhaustive dialysis in the cold, first against water and then against 0·1 *M* phosphate buffer at *p*H 6·5, using a modification of the system described by Wentzel and Sterne[5]. Maintenance of the original total nitrogen to tyrosine ratio of the aliquots at the end of dialysis was taken to indicate complete removal of the urea and guanidine hydrochloride, respectively.

Bovine serum albumin samples treated in the foregoing manner showed increases in relative viscosity, increased digestibility on incubation with trypsin and pepsin, and an increase in the intensity of the colour produced with Folin's reagent[6], as compared with the native albumin. Urea-denatured samples showed an increase in the available guanidinium groups detectable by the modified Sakaguchi reaction[7].

Electrophoretic patterns obtained in runs conducted at *p*H 6·5 (0·1 *M* phosphate buffer) and *p*H 8·6 (0·1 *M* diethylbarbiturate buffer) showed definite changes in the electrophoretic behaviour of denatured bovine albumin solutions, varying in extent



Patterns obtained from the descending limb showing the changes in the electrophoretic behaviour of urea-denatured bovine serum albumin. Perkin-Elmer Tiselius apparatus, 2·0 ml. cell, 165 V.-10 m.amp. current. Time of run in all cases, 86 min.
(a) 1·0 per cent native bovine serum albumin in 0·1 *M* diethyl barbiturate buffer, *p*H 8 6.
(b) 0·86 per cent urea-denatured bovine serum albumin in 0·1 *M* diethyl barbiturate buffer, *p*H 8 6.
(c) 0·86 per cent urea-denatured bovine serum albumin in 0·1 *M* phosphate buffer, *p*H 6 5

with different denatured aliquots, but characterized by decreased mobility and broadening of boundaries with double- and triple-notched peaks (see figure).

Aliquots which showed unequivocal denaturation effects, as determined by the foregoing criteria, were used in binding studies. Dialysis equilibrium experiments were carried out according to the method of Klotz and his associates[8] at 2° C., using a 24-hr. equilibration period. The outside dye concentration was varied in different experiments to bring $2 \cdot 45 \times 10^{-6}$ to $9 \cdot 8 \times 10^{-6}$ mole of dye per millilitre in contact with the protein molecules. The results uniformly showed a greater number of dye molecules bound by the denatured albumin as compared with the native. This is illustrated by the results in the accompanying table.

DATA FROM TYPICAL DIALYSIS EQUILIBRIUM EXPERIMENT
10 ml. 0·2 per cent protein solution inside bags except for control
Buffer: 0·1 *M* phosphate, *p*H 6 5, equilibration at 2° C. for 24 hr.

| | Residual free dye concentration (*M* × $10^{-6}$/ml.) | Moles dye bound per mole protein* |
|---|---|---|
| Buffer control | 6 72 | |
| Native bovine albumin | 5·76 | 24 |
| Guanidine hydrochloride denatured albumin | 5·22 | 32 |
| Urea-denatured albumin | 4·38 | 61 |

* Assuming a mol. wt. of 69,000 for bovine serum albumin.

It may be noteworthy that this effect appears to be much more marked when denaturation is effected by urea than when it is produced with guanidine hydrochloride. Different samples of bovine albumin denatured with guanidine hydrochloride also showed greater variation in the number of dye molecules (25–38 per mole albumin) bound in the presence of identical initial dye concentration than was observe with urea-denatured albumin (53–62 per mo albumin).

Assuming that partial reversal of denaturation the albumin takes place in spite of the rapid remov of the denaturing agents by dialysis, it appea significant that denaturation with urea and guanidin hydrochloride causes no decrease in the amount organic anion bound to the albumin; rather, i agreement with theory, it causes an increase in th number of bound dye molecules depending on th statistical distribution of uncoiled, partially coiled and 'native' molecules in a denatured protein solution. The loss of binding affinity for organic anion observed with heat-denatured albumin probabl represents a special case and not a general propert of 'denatured' bovine serum albumin.

The assistance of Mrs. Marilyn C. Harris an Mrs. Marian Spiro in these experiments is gratefull acknowledged. This investigation was supported i part by a grant of the U.S. Public Health Service National Institutes of Health.

## Decarboxylation of Collagen

INVESTIGATIONS in this department into the nature of the chrome tanning process have involved the preparation of various modified forms of collagen. Among possible modifications, the decarboxylation of collagen appeared to be of interest, although it has received scant attention from previous workers. Fox[1] reported that Grignard reagents had been used for decarboxylating an esterified polypeptide with the formation of a tertiary alcohol; more recently, Fromageot *et al.*[2] have used lithium aluminium hydride to reduce the terminal carboxyl groups of insulin to primary alcohols.

Collagen in the form of finely divided 'hide powder' was therefore treated with these reagents, and the dicarboxylic amino-acid content estimated by the method of Consden, Gordon and Martin[3]. Methylated collagen (0·86 m.mole OMe/gm. collagen) was treated with the Grignard reagent, methyl magnesium iodide, for 18 hr. Lithium aluminium hydride was dissolved in *n*-dibutyl ether and allowed to react with the hide powder for 12 hr. at 40° C. The metallo-protein complex formed in each case was decomposed by the addition of dilute mineral acid. The modified collagens produced were then washed with distilled water until free of salts. Analysis

| Treatment | Total side-chain carboxyl | Glutamic acid | Aspartic acid | Amide-nitrogen |
|---|---|---|---|---|
| None | 1·24 | 0·75 | 0·47 | 0·26 |
| Methyl magnesium iodide | 1·05 | 0·62 | 0·40 | 0·25 |
| Lithium aluminium hydride | 0·43 | 0·18 | 0·20 | 0·14 |

yielded the results shown in the accompanying table (expressed as m.mole/gm. dry protein).

It is seen that treatment of the methylated collagen with methyl magnesium iodide brings about a small reduction in the number of side-chain carboxyl groups. Lithium aluminium hydride, on the other hand, appears to effect more extensive reduction of the carboxyl group. In accordance with the work of Morrison *et al.*[4], some reduction of the amide groups was also observed.

It is hoped to publish full details of this work in the *Journal of the Society of Leather Trades Chemists*.

# Determination of Glycerol in Fermentation Solutions: a Rapid Chromatographic Procedure

A RAPID and simple chromatographic procedure has been developed in this laboratory for the determination of glycerol in solutions obtained by the sulphite-fermentation process of Cuban blackstrap molasses, and it is considered that the method may have wider applications. Neish[1] has described a chromatographic procedure for the determination of glycerol present in amounts up to about 5 mgm. in small samples of fermentation solutions. The present method is suitable for the determination of glycerol which may be present in amounts of the order of 500 mgm., thus permitting the use of a volumetric procedure for the final determination of glycerol.

It has been shown that glycerol is readily separated from sugars by partition chromatography on paper strips, and a number of solvents may be employed[2]. This was confirmed with acetone—a solvent easily separated from glycerol by distillation. It was found, however, that when the same solvent was employed in conjunction with large samples and columns of cellulose, glycerol could not be easily separated from sugars or the fermentable constituents of molasses; but excellent separation was obtained when alumina was used as adsorbent under the conditions described below, and the glycerol could be determined in the eluate by oxidation with sodium metaperiodate and direct titration of the formic acid produced[3].

The preliminary experimental work was carried out employing samples of molasses to which known amounts of glycerol were added. In addition to the unfermentable constituents and residual unfermentable organic impurities which are present in fermented liquors, molasses also contain large concentrations of fermentable sugars which cause serious interference with the 'periodate' procedure for glycerol. This imposed more rigorous conditions on the chromatographic procedure. In order to avoid strong retention of glycerol by the other constituents of fermentation solutions, it was found necessary to add a small amount of acetic acid to the solution of the sample and to the solvent employed for extraction.

The chromatographic method involves the preparation of a column of coarse-grade cellulose powder (2·5 gm.) (Whatman), which acts as a support for chromatographic alumina (5 gm.)[4]. Sufficient of the sample is taken to give up to about 0·5 gm. glycerol. It should contain about 3 ml. water, its volume being 5 ml. (approximately). Sulphite fermentation solutions analysed in this laboratory contained glycerol in concentrations up to 12 per cent. After addition of sodium sulphite (0·5 gm.), sodium acetate (1 gm.) (these compounds assist in the retention of sugars and impurities by the adsorbent) and acetic acid (0·1 ml.) to the sample, the resulting solution is mixed with alumina (15 gm.) and the mixture then transferred to the prepared column. The glycerol is eluted with 250 ml. of solvent (acetone containing 5 per cent v/v water and 0·05 per cent v/v glacial acetic acid).

It was found that there is a small but constant retention of glycerol by the alumina adsorbent; but this difficulty was easily overcome by standardizing the caustic soda solution for the procedure, using 1 gm. molasses to which a known amount of glycerol had been added.

Employing the procedures described, typical results for the recovery of glycerol from mixtures with Cuban blackstrap molasses are given in the accompanying table. Similar results were obtained for fermentation liquors to which known amounts of glycerol had been added.

| Weight of molasses (gm.) | Weight of glycerol added (gm.) | Titration (ml. 0·1 *N* NaOH) | Factor* (gm. glycerol ≡ 1 ml. 0·1 *N* NaOH) |
|---|---|---|---|
| 1 | Nil | 0·4 | — |
| 1 | 0·7500 | 80·4 | 0·0094 |
| 1 | 0·3333 | 35·8 | 0·0094 |
| 1 | 0·2499 | 27·0 | 0·0094 |
| 1 | 0·0833 | 9·1 | 0·0096 |

* Theoretical value = 0·0092 (value which would be obtained in the complete absence of glycerol hold-up).

A mixture of 0·1 gm. each of sucrose, glucose and mannitol gave a titration of only 0·3 ml. 0·1 *N* sodium hydroxide. The total amount of material extracted from a mixture of 0·3 gm. each of these compounds was less than 1 mgm., whereas when cellulose alone was used 80 mgm. was extracted.

The method has been applied to the analysis of solutions from the alkaline fermentation process of Eoff, Linder and Beyer[5].

Full details of this work will be published at a later date.

## An Occurrence of Aluminium Succinate in *Cardwellia sublimis* F. Muell.

ALUMINIUM succinate has been found as a massive deposit in a cavity in the heartwood of *Cardwellia sublimis* F. Muell. (Proteaceæ), commonly known as northern silky oak or bull oak. This is a commercial timber tree restricted to the rain forests of tropical Queensland. The deposit occurred in a so-called 'wind shake' in a log from Jarra Creek near Tully, North Queensland. Inquiries from foresters and saw-millers indicate that such occurrences are rare. The log was about 10 ft. in girth, and the deposit apparently extended from the base to at least 25 ft. up the stem of the tree. A similar occurrence of aluminium succinate has been previously recorded[1] in *Orites excelsa* R. Br. (Proteaceæ), popularly known as silky oak or prickly ash, a timber tree of the subtropical rain forests of New South Wales. Basic aluminium succinate was also identified as a white deposit in the galleries of a longhorn beetle in timber of *Qualea* sp. (Vochysiaceæ) from South America[2].

The present deposit was a loosely aggregated greyish-white powder, which lost 41·2 per cent by weight when dried at 100° C. The alumina content of the dried material was 40·9 per cent, and of the ash 99·9 per cent. The formula for basic aluminium succinate calculated by Smith (*loc. cit.*), which would agree with this result, is $Al_2(C_4H_4O_4)_3.Al_2O_3$, but Campbell *et al.* (*loc. cit.*) doubt its validity. Qualitative analysis, confirmed by Dr. F. N. Lahey of the Chemistry Department, University of Queensland, failed to reveal the presence of metals other than aluminium, or organic acids other than succinic acid. The succinic acid, purified by sublimation, was identified by melting point and mixed melting point with an authentic sample. Purification of the original sample by crystallization was impracticable, owing to its complete insolubility in a wide range of solvents; consequently the exact composition was not determined.

Samples of bark and wood from another log of *Cardwellia sublimis* from Tully contained approximately 1·09 and 0·86 per cent alumina and 2·8 and 9·7 per cent ash respectively on a dry-weight basis. The ash of bark and wood contained approximately 40·0 and 82·6 per cent alumina respectively.

The physiological significance of the accumulation of aluminium in large quantities by certain plants is obscure. Chenery[3] has suggested that this accumulation may have some value in taxonomy; and a survey was made of aluminium-accumulating species in the Queensland–New Guinea flora, using the aluminon test[3]. The occurrence of aluminium (>1,000 p.p.m.) in these plants exhibits a remarkable degree of specificity. Its taxonomic and ecological implications for the local flora will be discussed elsewhere.

## Alkaloids of *Datura innoxia*

THE brief reference in *Nature* of December 13, p. 1002, to a paper by James and Thewlis[1] on the separation and identification of solanaceous alkaloids in normal and grafted plants of *Atropa belladonna* and *Datura innoxia* prompts us to place on record certain results we have obtained in a similar study. So far as we are aware, the alkaloids of *D. innoxia* have not hitherto been fully characterized[2]. James and Thewlis state that they found hyoscine and hyoscyamine to be present and, from evidence of the hyoscine : hyoscyamine ratios in the two plants and in their reciprocal grafts, have deduced that alkaloid synthesis occurs mainly in the roots.

Three samples of *D. innoxia* Miller (see Timmerman[3]), one from the 1950 crop and the others from the 1952 crop, were analysed by the method described previously[4,5], and the presence of hyoscine (0·24, 0·30 and 0·37 per cent) was confirmed. The fraction at first considered to be hyoscyamine (0·035, 0·062 and 0·073 per cent) afforded a picrate of melting point considerably below that of hyoscyamine picrate. This material, on fractional crystallization from water, gave two picrates, one of melting point 162–164° C., undepressed on admixture with authentic hyoscyamine picrate, and the other, melting point 175–176° C., undepressed on admixture with authentic meteloidine picrate. It is therefore apparent that, in addition to hyoscine and hyoscyamine, *D. innoxia* contains meteloidine. There is indirect support for this conclusion in certain discrepancies between the acidimetric and colorimetric values for hyoscyamine[1]; meteloidine does not give a colour in the Vitali–Morin test. In *ad hoc* experiments, it has been confirmed that hyoscyamine and meteloidine are not separated by the chromatographic method employed both by us and by James and Thewlis.

From an extension[5] of our earlier experiments[6] on grafts within the same genus, the simplest conclusions with respect to *D. innoxia* are that the main site of alkaloidal syntheses are the roots for hyoscine and the aerial parts for hyoscyamine; the site of synthesis of meteloidine has not been located.

## Resistance of Hop Stems to Invasion by *Verticillium albo-atrum*

MOST fungi causing vascular wilts of plants enter through the roots and then invade systemically the xylem tissue of the root and stem. Their effects are usually judged by the severity of leaf symptoms, and on this criterion is based an assessment both of host resistance and of fungal pathogenicity. The extent and intensity of fungal growth in the xylem (particularly of the stem) parallels the severity of leaf symptoms, and is also used as an indication of host resistance and fungal pathogenicity[1–4].

If a host species or variety has high resistance to a particular strain of wilt pathogen, fungal invasion is slight. The xylem of the root is slightly invaded, and if the fungus enters the stem, its growth there is slight and attenuated. Conversely, the xylem of a plant of low resistance becomes extensively invaded, in both root and stem.

The hop varieties *OR55* and Fuggle possess respectively high and low resistance to the virulent race of *Verticillium albo-atrum* and demonstrate the phenomena described[1]. Similar effects are seen when plants of Fuggle are infected with one or other of the two races of *V. albo-atrum* of differing pathogenicity (one mild and the other virulent)[2]. The tomato varieties Pan America and Bonny Best have respectively high and low resistance to *Fusarium oxysporum lycopersici* and also display the phenomenon of differential fungal growth within them[4,5].

Roots of wilted plants are rarely studied, the assessments of disease usually being made on the stems. Since it is well known, however, that slight fungal growth in the stems is associated with slight fungal growth in the roots, and vice versa, the natural assumption appears to have been made that the whole plant (root and stem alike) provides a medium of uniformly high or low resistance to invasion. From this assumption arises a further one, namely, that the normal stems of plants of high and low resistance are intrinsically different in their reaction to the pathogen. This appears so axiomatic that it has been used as a basis for the study of the causes of resistance to wilt pathogens. Several workers have thus investigated the action of fungal toxins on healthy stems[6,7] or attempted to isolate compounds from stems of plants of high resistance which should not (theoretically) be present in stems of plants of low resistance[8]. Such studies have, in general, revealed no differences between the stems.

The present work on hops, at the East Malling Research Station, has attempted to differentiate between stem and root reaction, and to study the reactions of stems from varieties of differing resistance when grown under uniform conditions. If stems of such varieties are invaded from their own roots, their reactions are not being tested under identical conditions, since (*a*) they are growing on roots of differing varietal status and (*b*) these roots are differentially invaded. Two methods of studying the reaction of hop stems free from the effects of these factors have been used: (1) infection through rootstocks of another variety, and (2) direct stem inoculation of one variety with strains of *V. albo-atrum* to which plants of this variety show a differential response when root-inoculated.

*Grafting experiments*. Reciprocal rootstock–stem grafts were made of the varieties *OR55* and Fuggle (controls being grown on their own (grafted) roots). The plants were infected through these new roots by infesting the soil with a virulent strain of *V. albo-atrum*. When infected through Fuggle roots, both *OR55* and Fuggle stems became heavily invaded and died. When infected through *OR55* roots, both became lightly invaded and showed only mild symptoms. Thus under equal root-invasion conditions, the stems of both varieties showed an equal reaction. They were thus equally resistant.

*Stem inoculation experiments*. Stems of the Fuggle variety, growing on their own (healthy) roots, were directly inoculated with the two races of *V. albo-atrum* (mild and virulent). Two inoculation methods were used. When a small drop of spore suspension of either race of the fungus was introduced directly into the stem xylem, both races caused only mild wilt, and grew in an attenuated fashion in the stem above the point of inoculation. When a large amount of spore suspension of either race was put into a pith cavity, both races caused severe wilt, accompanied by extensive xylem invasion. The roots on all plants remained uninvaded. These results indicate that the reaction of the Fuggle stems was not determined by the race of fungus but by the conditions of invasion. When invaded from a small inoculum in the xylem, resistance of the stems was high; when invaded from a large inoculum in the pith cavity, this resistance was either reduced or overcome. The fact that stem reaction could thus be changed shows that, although not affected by fungal strain, the stems were not functioning as purely inert growth media for the pathogens.

Somewhat similar tests of inoculum dose have been made with the two races on Fuggle roots. In this case the size of the inoculum did not affect the severity of wilt or the growth of the fungus in the plant. The mild race invariably caused mild wilt and the virulent race caused severe wilt. Roots thus seem to differ fundamentally from stems in that their resistance is related to fungal virulence and not to dose of inoculum.

The results suggest the following conclusions on the mechanism of invasion of varieties of differing resistance. The site of differential resistance is in the roots. The stems of varieties of high or low resistance show equal resistance to both strains of the pathogen. Under conditions of mild root-invasion, this resistance is high; but in a variety of low resistance the host–parasite association in the roots causes stem resistance to be reduced or overcome. The following possible reasons for this are suggested as a basis for further study: (1) A reduction of stem resistance by: (*a*) diffusion of toxins from the invaded roots; (*b*) impairment of normal root-function. (2) Increase in the invasive power of the fungus by: (*a*) establishment of a suitable 'inoculum potential'; (*b*) diffusion of fungal accelerators.

The main conclusions may be widely applicable to vascular wilts. The results of Heinze and Andrus[5] suggest a similar relationship in the case of tomato wilt (although Scheffer and Walker[9] have recently disputed this). Wardlaw's observations[10] that the pseudostem of banana could only be infected through roots are also in agreement. If, in fact, the present conclusions are of general application, they may necessitate a re-orientation of previous views on the mechanism of parasitism by vascular pathogens and suggest a new approach to the study of host resistance. The experiments are to be reported in detail elsewhere.

## Use of Repellents to simplify Insecticide Field Trials

A DIFFICULTY frequently met in insecticide field trials is that although the insecticide application may kill the insects on the treated plots at the time, these plots may be re-invaded very quickly by insects from the control plots and surrounding untreated areas. This is particularly marked in the case of trials on the control of cotton *Lygus* (*Lygus vosseleri*, Popp.), where the greater part of the damage is done by an immigration of highly mobile adults into the crop. One method of avoiding this difficulty is to use large plots of several acres in extent; but the very size of the plots seriously reduces the precision of an experimental comparison, besides being very expensive in time, materials and labour. Recent work has shown that where the principal purpose of the experiments is to study the effect of *Lygus* upon the yield of cotton, the result may be obtained very much more simply by using the repellent effect of certain insecticides.

During 1951 it was noticed that where small units of cotton, two rows of twenty plants each, scattered at random throughout a largely unsprayed field, were sprayed to 'run-off' level each week with 0·1 per cent DDT, they were quite free from signs of *Lygus* damage, while untreated plants, even in adjacent rows, showed signs of very heavy damage. Since a DDT deposit of this type takes up to twenty-four hours to kill adult *Lygus*, it was felt that this protection must have been due to a repellent effect of the insecticide.

Following this indication, laboratory experiments were carried out to investigate possible repellent effects of DDT and 'Toxaphene' deposits. Adult *Lygus* of both sexes were placed in small cages and offered a choice of treated and untreated sorghum heads as food. Approximately every ten minutes the numbers of *Lygus* on treated and untreated heads were counted. After each count the cages were shaken to dislodge feeding *Lygus* and the cages rotated through 180°.

Table 1. TOTAL NUMBERS OF VISITS MADE BY ADULT *Lygus* TO TREATED AND UNTREATED *Sorghum* HEADS

| | Treated | Untreated | |
|---|---|---|---|
| Trial 1 | 50 | 165 | Treated *Sorghum* dipped in 0·1 per cent DDT and dried. Ten *Lygus*/cage. Two cages per trial |
| Trial 2 | 34 | 71 | |
| Trial 3 | 20 | 62 | |
| Trial 4 | 20 | 51 | |
| Means | 31 | 87 | |
| Trial 5 | 24 | 180 | Treated *Sorghum* dipped in 0·2 per cent 'Toxaphene' and dried. Ten *Lygus* per cage. Two cages per trial |
| Trial 6 | 11 | 38 | |
| Trial 7 | 46 | 162 | |
| Means | 27 | 127 | |

Assuming that in the absence of repellent effects the numbers of visits to treated and untreated heads would have been similar, the $\chi^2$ test shows that DDT and 'Toxaphene' deposits are highly significantly repellent to adult *Lygus* of both sexes ($P < 0{\cdot}001$).

This effect was confirmed in the field during the 1952 cotton season. Ten single rows of twenty plants each were marked out at random in a two-acre cotton strip. Five of these were sprayed to 'run-off' level with 0·2 per cent 'Toxaphene' and five with 0·1 per cent '*C.R.* 686', a systemic phosphorous insecticide. Insecticide applications were made at weekly intervals during the period of *Lygus* immigration. For the purpose of comparing damage on sprayed and unsprayed plants, the tenth row to the right of each sprayed row was taken as a control.

Towards the end of the *Lygus* attack the third, fourth, fifth and sixth leaves from the top of the plant were graded on an arbitrary scale of damage ranging from 0, for no signs of damage, to 4 for a leaf completely shredded and tattered. Counts were made on fifteen plants on each treated and control row. The results are shown in Table 2.

Table 2. MEAN GRADE OF DAMAGE PER LEAF

| | |
|---|---|
| Rows sprayed with 'Toxaphene' | 0·79 |
| Rows sprayed with '*C.R.* 686' | 0·33 |
| Untreated control rows | 1·91 |

Analysis of the detailed records showed that differences between treated rows and untreated controls were highly significant ($P < 0{\cdot}001$).

A detailed examination of 15 plants in each row was also made, and the percentage of fruiting points formed up to that date which had been shed was calculated (see Table 3).

Table 3. MEAN PERCENTAGE OF FRUITING POINTS SHED

| | |
|---|---|
| 'Toxaphene' sprayed rows | 7 per cent |
| '*C.R.* 686' sprayed rows | 7 per cent |
| Control rows | 13 per cent |

For the analysis of the shedding records an angular transformation was used and the differences between treated and control rows shown to be highly significant ($P < 0{\cdot}001$).

Thus it has been shown that in a cotton field where large numbers of more attractive unsprayed plants are readily and closely available the deterrent effects of certain insecticide deposits are sufficiently strong to keep the treated plants free from *Lygus* damage. Conversely, the yield loss due to *Lygus* in unsprayed cotton may be readily estimated by using this method to protect a small proportion of the plants in the field.

This relatively simple and economical method of studying the effects of *Lygus* upon cotton yield is now being developed, and a detailed paper will be published elsewhere at a later date.

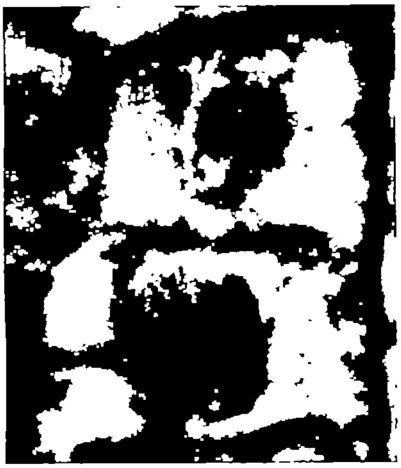
## Virus-induced Nucleolar Abnormalities in Tomato

IN view of current opinions on the nature of virus particles[1], recent work carried out in this department on the effect of the 'aspermy' virus upon nuclear, and especially nucleolar, behaviour in plant cells may have a special significance. Caldwell[2] reported prophase collapse in diseased pollen- and embryo-sac mother cells in tomato, accompanied by peculiarities of nucleolar behaviour, and Wilkinson[3] has observed similar meiotic abnormalities in *Nicotiana glutinosa*. Recent examination of somatic divisions in diseased tomato and tobacco plants has revealed the occurrence of widespread nucleolar and other abnormalities, some of which recall the aberrations regarded as typical of the cell-divisions found in malignant animal tissue; for example, arrested metaphase, collapse at metaphase, spindle malformation and breakdown, tendency to form giant nuclei, etc. In particular, abnormal persistence of the nucleolar material, and sometimes an apparent multiplication of nucleolar bodies during the mitotic cycle, have been very striking. Thus, in dividing cells of root tips obtained from tomato shoots heavily infected with the 'aspermy' virus, the nucleolar material,



Cells from root tissue of diseased tomato showing collapsed metaphase and (lower) nucleolar vesicle and one-sided spindle at early anaphase. × 1,000

instead of dispersing during prophase, persists through anaphase in the form of one or more prominent and somewhat elongated vesicles. The accompanying photograph shows a typical dividing nucleus at early anaphase, with the nucleolar vesicle in a central position upon the somewhat distorted spindle; incidentally, in the cell above can be seen an example of metaphase collapse. Similar results have been obtained in tobacco species infected with the same virus.

This postponement of the utilization of nucleolar material by the contracting chromosomes, normally completed by early metaphase (when the pellicles which invest the chromosomes are fully formed), provides further support for the view that there is competition between the virus particles and chromonematal material for nucleoprotein contained in the nucleolus. This view was formulated by me at a meeting last year of the Society for the Study of Fertility and mentioned in *Nature* (August 9, 1952). A detailed account of the work is being prepared for publication.

## Polyploidy in *Primula farinosa* L.

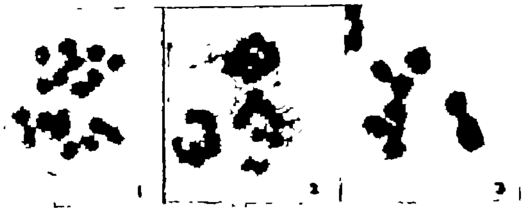
THE discovery of a tetraploid form of *Primula farinosa* on the Baltic island of Gotland during the summer of 1950 was somewhat unexpected, as hitherto this plant has seemed a well-defined diploid species ($n = 9$), at least in Central and Northern Europe. This tetraploid form revealed $n = 18$ at meiosis (Fig. 1), and the plant appeared morphologically distinct from the British *Primula*, with more elongated spatulate leaves (Fig. 4).

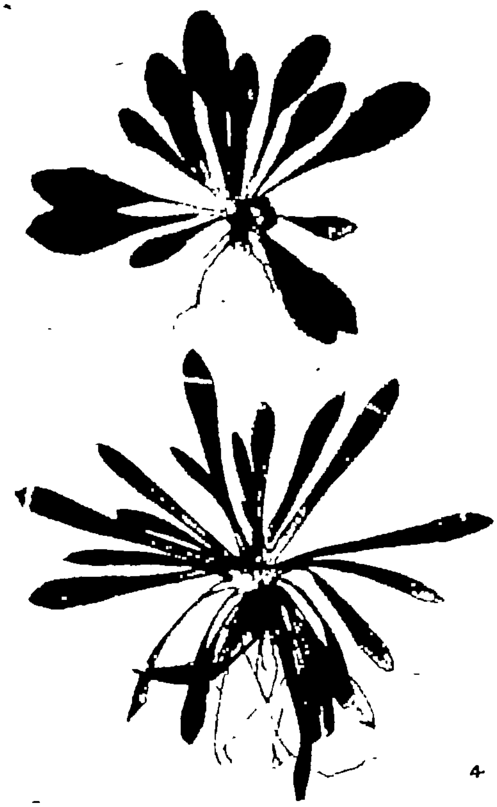
This led to a more comprehensive study of *P. farinosa* in Great Britain. However, all specimens collected on Widdybank Fell, Teesdale, in May 1952 proved to be diploid with $n = 9$ (Fig. 2); and a further survey of the *Primula* from other limestone areas in Yorkshire, Durham and Westmorland has so far revealed the same result; but in every case the chromosomes seemed smaller than those of the tetraploid form.

However, the intricacies of this species are considerable, and indicate a cytological complexity that was not visualized in the first instance, for plants of *P. farinosa* var. *acaulis* collected on Gotland, and kindly sent to me by Dr. Bengt Pettersson, have also proved to be diploid with $n = 9$ (Fig. 3). However, the chromosomes of this plant are considerably larger than those of the British diploid and the Swedish tetraploid (Figs. 1, 2 and 3), and a gene difference for chromosome size is therefore suspected. Thus the diploid and tetraploid forms of this species are both represented on the Baltic island of Gotland, which has for many years been renowned for its peculiar and interesting flora, rich in endemics.

These preliminary results indicate the complexity of the problem, and the tetraploid plants produce an interesting connecting link between the original diploid form of *P. farinosa* and the other members of the sub-section Farinosae, which give rise to a very long polyploid series: *Primula farinosa*, $n = 9$; *P. farinosa*, $n = 18$; *P. scotica*, $n = 27$; *P. scandinavica*, $n = 36$; *P. stricta*, $n = 63$.

However, it is now clear that a more detailed cytological survey of this group, from all over its geographical range, is desirable. I should be most





(Above) Meiotic metaphases in acetocarmine of forms of *Primula farinosa*. × 1,200. (1) Tetraploid from Gotland; (2) diploid from Teesdale; (3) diploid from Gotland.
(Below) (4) *Primula farinosa*, above from Teesdale, below from Gotland

grateful for any living plants or seeds of *P. farinosa*, *P. scotica*, *P. scandinavica*, *P. stricta* and *P. finmarchica* from Great Britain, Europe and North and South America.

## Habitat of *Polycelis felina* (= *cornuta*) and *Crenobia alpina* in the British Isles

THE few text-books on freshwater biology which refer particularly to the British Isles regard *Polycelis felina* and *Crenobia alpina* as stenothermous, stream-dwelling species. Beauchamp[1], however, showed that *C. alpina* inhabited suitable shores of some Cumberland lakes during the winter; but he considered that summer temperatures were too high for their occurrence in lakes at this season. The generally accepted view is that in the British Isles these two species cannot establish themselves where the temperature exceeds 13°–15° C. in the case of *C. alpina*[1,3] and 16°–17° C. for *P. felina*[3]. On the Continent, Theinemann[4] considered that the widest range of *C. alpina* and *P. felina* was 0·7°–15° C. and 0·5°–15·75° C. respectively. It has been reported several times from the Continent that *Crenobia alpina* is a permanent member of the fauna of Alpine and other mountain lakes where a suitable substratum occurs (for references see Beauchamp[1]).

During a survey of the freshwater triclads of the lochs on Islay (Argyll), *Polycelis felina* was found in six of them in July 1952 during a spell of warm weather when the average maximum air temperature, as recorded on Colonsay, was 20° C. and the average 16° C., following a June of average warmth. Its abundance varied from a small to an exceedingly large population (see table). Twenty-three lochs in all were examined, and of these eleven were judged to provide a stony, wave-washed shore suitable for *P. felina*. These lochs are listed in order of concentration of calcium ions in the accompanying table—the number of *P. felina* and the total triclad population (*P. nigra* and/or *P. tenuis*) taken per unit hour of collecting is also recorded. It is clear that this supposedly typical stream species occurred in some lochs in great abundance, and in four was numerically the dominant species. There can be no question that here it formed a typical component of the lake fauna and was not restricted to areas near streams; there is no reason for supposing that it is not a permanent member. It is also interesting to note that *P. felina* reached its greatest abundance in the more calcareous lakes. According to Carpenter[2], this is contrary to the view expressed by Bornhauser, who observed that this species was markedly absent from streams with a high lime content. The explanation, however, may lie in the interpretation of the term 'high'. Loch Finlaggin, and to a lesser extent Loch Gorm also, are exceptions to the calcium ion – *P. felina* trend. The former had a relatively high population of *P. tenuis*, and competition may explain the absence of *P. felina*; while Loch Gorm had a shore of stones lying on sand which would be disturbed during wind action and become most harmful to soft-bodied triclads.

| Loch | Calcium (mgm./l.) | *P. felina* (1 hr. collecting) | Total triclads | Loch type | Height above sea-level (ft.) |
|---|---|---|---|---|---|
| nam Ban | 1·6 | Nil | Nil | Hill loch | 350 |
| Cam | 2·8 | Nil | 20 | Hill loch | 300 |
| Ardnahoe | 2·8 | 81 | 162 | Hill loch | 200 |
| nan Gillean | 4·4 | Nil | 248 | Hill loch | 300 |
| Gearach | 4·8 | Nil | Nil | Peaty hill loch | 250 |
| Gorm | 8·8 | 8 | 16 | Coastal loch—sandy | 50 |
| Skerrols | 9·6 | 140 | 216 | Lowland loch | 75 |
| Finlaggin | 15·6 | Nil | 210 | — | 170 |
| Lossit | 16·4 | 324 | 324 | Hill loch | 300 |
| Cadharn | 19·2 | 346 | 442 | Hill loch | 230 |
| Ballygrant | 23·2 | 228 | 264 | Hill loch | 230 |

Considering now *Crenobia alpina*, this species was not recorded from the Islay lochs, but was collected from Loch Baile à Ghobhain and Loch Fiart on Lismore Island, and from Loch Restil (Argyll) in July 1951. The former two are low-lying, calcareous lochs (calcium, 50 mgm./l.) and the triclads were taken from exposed, stony shores. In more sheltered bays, *C. alpina* was absent and *Polycelis nigra* occurred. Loch Restil is a small, lime-poor (calcium, 2·4 mgm./l.) hill loch at approximately 800 ft. above sea-level. At the time, the records were considered as examples of aberrant behaviour, perhaps due to the drying-up of streams. However, on the clear-cut evidence of the Islay records for *P. felina*, they may be better regarded as examples of the lake-dwelling habit of *C. alpina* in the British Isles.

It is generally considered that these two triclads are limited in their distribution by their stenothermy, or associated oxygen tension[5]. Examination of average maximum July air temperatures for the British Isles (1901–30) shows that Islay, by virtue of its maritime position, lies north of the 62° F. (16·7° C.) isotherm; Lismore is 1°–2° F. warmer. Allowing for the lower temperature of lake water and the certainty of periods of average temperature greater than 16·7° C. (average annual maximum temperature for Islay, 1901–30, was approximately 22·5° C.), the habit may still fit with the physiological explanation, particularly in the case of *P. felina*. (It is hoped to arrange for water temperatures to be recorded in one of the Islay lochs during the summer.) Thus *P. felina* and perhaps *C. alpina* may be permanent lake-dwellers in the northern part of the British Isles, but confined to streams farther south. *P. felina* was recorded from a stony beach in Windermere during August 1950, but during a period of heavy rainfall and near the entry of a stream.

Different varieties of *P. felina* have been described by Theinemann, and it will be interesting to compare the Islay loch specimens with stream-dwelling forms. Living collections of Islay material have been submitted to Mr. Anders G. Dahm, University of Lund, Sweden, who is working on the taxonomy and ecology of this species.

I am grateful to the Nature Conservancy for defraying expenses for the field-work, and to the Meteorological Office for supplying data of temperatures for Colonsay.

T. B. REYNOLDSON

Department of Zoology,
University College of North Wales,
Bangor. Oct. 25.

# FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

## Monday, April 13

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Relative Merits of Broad-Band Transmission by Beam, Cable and Waveguide" (to be opened by Mr. E. C. H. Organ).

Society for General Microbiology (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. D. D. Woods: "The Integration of Research on the Nutrition and Metabolism of Micro-organisms" (First Marjory Stephenson Memorial Lecture).*

## Monday, April 13—Thursday, April 16

Ergonomics Research Society (in the Department of Human Anatomy, The University, Oxford).—Symposium on "Human Performance—its Measurement and Limitations".

## Monday, April 13—Friday, April 17

Physical Society (at the Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7).—37th Exhibition of Scientific Instruments and Apparatus

Tuesday, April 14

At 6.45 p.m.—Dr. E. C. Bullard, F.R.S.: "Seismic Study of the Ocean Basins".

Wednesday, April 15

At 6.45 p.m.—Dr. L. A. Jordan: "Particles, Pellicles; Pigments, Paints and Physics".

Thursday, April 16

At 6.45 p.m.—Prof. W. V. Mayneord: "Scintillation Counting and its Medical Applications".

## Tuesday, April 14

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. G. G. Haselden: "The Fractionation of Liquid Air".

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. T. Kilburn, Mr. G. C. Tootill, Mr. D. B. G. Edwards and Mr. B. W. Pollard: "Digital Computers at Manchester University"; Mr. B. W. Pollard and Mr. K. Lonsdale: "The Construction and Operation of the Manchester University Computer"; Dr. T. Kilburn and Mr. G. Ord: "Universal High-Speed Digital Computers—a Decimal Storage System"; Prof. F. C. Williams, F.R.S., Dr. T. Kilburn, Mr. G. N. W. Litting, Mr. D. B. G. Edwards and Mr. G. R. Hoffman: "Recent Advances in Cathode Ray Tube Storage".

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Annual General Meeting; at 7 p.m.—Films: "Basic Principles of Lubrication", "Krilium".

Society of Public Analysts and Other Analytical Chemists, Polarographic Discussion Panel of the Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Papers on "Polarography".

## Wednesday, April 15

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. L. Landon Goodman: "Materials Handling and Processing".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Maurice Black: "The Constitution of Chalk".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Annual General Meeting; Sir Charles Normand: "Monsoon Forecasting" (Presidential Address).

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Prof. B. K. Johnson: "Microscopy in the Region of Wave-length $\lambda = 2000$ A. to 1000 A."; Mr. R. J. King and Dr. E. M. F. Roe: "Optical Conditions for Quantitative Ultra-Violet Microspectroscopy".

Society of Chemical Industry, Corrosion Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. F. C. Porter: "The Corrosion of Aluminium and its Alloys in Supply Waters".

## Thursday, April 16

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. K. A. Kermack: "A Biometrical Study of *Micraster coranguinum* and *Isomicraster senonensis*"; Mr. B. Nicolai and Mr. R. D. Preston: "Cell Wall Studies in the Chlorophyceae".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Shiou-Chuan Sun: "Frothing Characteristics of Cresylic Acids in Flotation"; Dr. J. S. Webb: "A Review of American Progress in Geochemical Prospecting and Recommendations for Future British Work in this Field".

London Mathematical Society (at University College, Cardiff), at 5 p.m.—Dr. G. Higman: "p-soluble Groups".

Society of Chemical Industry, Road and Building Materials Group (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Annual General Meeting; Mr. A. W. Christie: "Road Surfaces as Reflectors of Light, from the Point of View of Street Lighting".

Society of Chemical Industry, Microbiology Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p.m.—Dr. Lois Dickinson: "The Use of the Bacteriophage in the Study of Viruses"; Mr. L. J. Meanwell: "Bacteriophages of the Lactic Streptococci".

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Dr. A. E. Jones and Dr. A. Gluckmann: A Discussion on "The Carcinogenic Effects of Radiation".

## Thursday, April 16—Saturday, April 18

Faraday Society (at the Royal Institution, 21 Albemarle Street, London, W.1).—Fiftieth Anniversary Celebrations, and General Discussion on "Equilibrium Properties on Solutions of Non-Electrolytes".

## Friday, April 17

Institution of Chemical Engineers, Graduates' and Students' Section (in the Large Chemistry Theatre, University College, Gower Street, London, W.C.1), at 10 a.m.—Symposium on "Effluent Disposal".

Association of Applied Biologists (in the Surveying Lecture Theatre, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 11 a.m.—Annual General Meeting; at 2.30 p.m.—Mr. R. W. Marsh: "The Past and Future of the *Annals of Applied Biology*" (Presidential Address)

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Discussion of Geophysical Papers received during the Session.

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Annual General Meeting; at 7.30 p.m.—Dr. Wm. Mitchell: "Isolation of Fine Chemicals from Natural Sources"

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer in the Department of Pharmaceutics, University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (April 18).

Speech Therapist (part-time) to the Godalming Clinic—The County Medical Officer, County Hall, Kingston-upon-Thames, Surrey (April 18).

Lecturers in Anatomy, Physiology and Pathology, and Lecturers or Assistant Lecturers in Civil Engineering and Mechanical Engineering, at University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (April 20).

Research Assistant in the Department of Chemistry, for work on ionic melts—The Professor of Chemistry, Queen's University, Belfast (April 20).

Light Current Electrical Engineer at the Royal Aircraft Establishment, Farnborough, for development of variety of precision electrical equipment and its application to research problems in aircraft flight control—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.114/53A (April 25).

Physical Chemist or Physicist (Scientist, Grade I) to take charge of investigations on the structure of coke—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, Glos, quoting TT/611 (April 25).

Assistant Lecturer in the Department of Chemistry—The Secretary and Registrar, University College of North Wales, Bangor (April 27).

Director of the Tasmanian Museum and Art Gallery—The Agent-General for Tasmania, 457 Strand, London, W.C.2 (April 30).

Research Officers (Scientific Officer grade) to work on sugar beet breeding and cereal breeding—The Secretary, Plant Breeding Institute, School of Agriculture, Cambridge (April 30).

Research Studentships to senior undergraduates reading zoology—The Director, Zoological Society of London, Regent's Park, London, N.W.1 (April 30).

Senior Lecturer in the Department of Veterinary Pathology—The Secretary of University Court, The University, Glasgow (April 30).

University Lecturer and one or more University Assistant Lecturers in Mathematics—The Secretary of the Faculty of Mathematics, Arts School, Bene't Street, Cambridge (April 30).

Assistant in Physical Chemistry at University College, Dundee—The Secretary, The University, St. Andrews (May 1).

Lecturer or Assistant Lecturer in Chemistry at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 1).

Senior Lecturer in Inorganic Chemistry, and Lecturers or Assistant Lecturers in Botany, Chemistry, Mathematics, Parasitology, and Zoology, at University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 1).

Lecturer in Public Health Engineering—The Head of the Department of Civil Engineering, Imperial College of Science and Technology, South Kensington, London, S.W.7 (May 2).

RESEARCH ASSISTANT TO WORK IN BEEKEEPING RESEARCH DEPARTMENT on problems relating to honey bees and their management—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (May 5).

ASSISTANT LECTURER IN CHEMISTRY, and an ASSISTANT LECTURER IN ZOOLOGY—The Registrar, University College, Cathays Park, Cardiff (May 9).

LECTURER IN THE HISTORY OF SCIENCE—The Secretary of Faculties, University Registry, Oxford (May 9).

ENGLISH ELECTRIC CO. STUDENTSHIP IN AERONAUTICS—The Deputy Registrar, City and Guilds College, Exhibition Road, London, S.W.7 (May 15).

ENTOMOLOGIST, and a RESEARCH OFFICER—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (May 15).

MAHENDRALAL SIRCAR PROFESSOR OF PHYSICS—The Registrar, Indian Association for the Cultivation of Science, Jadavpur, Calcutta 32, India (May 15).

ORGANIC CHEMIST (Senior Research Officer grade)—The Director, Laboratory of Human Nutrition, Oxford (May 16).

SCIENTIFIC OFFICER IN THE ENTOMOLOGY DEPARTMENT, to work probably on problems of soil arthropods or other invertebrates—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (May 16).

SENIOR RESEARCH OFFICER to undertake research on the kinetics of the gasification reactions of coal under high pressure, a RESEARCH OFFICER to undertake research on the influence of ash catalysis on the reactions which occur during the complete gasification of coal, a RESEARCH OFFICER to undertake research directed at the improvement of methods for the analysis and testing of brown coal, and gas mixtures which result from its gasification, a TECHNICAL OFFICER to undertake the analysis and testing of coal, ash, fuel gases, and other materials associated with the pilot plant investigation of the gasification of brown coal, a TECHNICAL OFFICER to assist in pilot plant research on the gasification of coal under high pressure, and a TECHNICAL OFFICER to develop techniques for the investigation of the sintering and fusion of coal ash; in the Chemical Engineering Section of the Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Ref. 590/439 (May 16).

UNIVERSITY DEMONSTRATOR IN BOTANY—Dr. A. S. Watt, Department of Botany, Downing Street, Cambridge (May 16).

ASSISTANT LECTURER IN ARCHÆOLOGY—The Registrar, University College, Cathays Park, Cardiff (May 30).

COATS FELLOWSHIP IN CHEMISTRY or PHYSICS—The Clerk of the Senate, The University, Glasgow, W.2 (May 31).

ORNITHOLOGIST (Professional Officer grade), an ENTOMOLOGIST (Assistant Professional Officer grade) and a HERPETOLOGIST (Assistant Professional Officer grade)—The Director, Transvaal Museum, P.O. Box 413, Pretoria, South Africa (May 31).

ASSISTANT LECTURER IN BOTANY—The Registrar, University College, Exeter.

ASSISTANT TECHNICAL SECRETARY (with a degree in metallurgy) TO THE METALLURGY (General) DIVISION—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Technical Secretary'.

ENTOMOLOGIST to develop a field technique to control biting midges, and a TECHNICAL ASSISTANT graduate or technician to assist in investigating the larval ecology of midges—Dr. D. S. Kettle, Department of Zoology, West Mains Road, Edinburgh 9.

EXPERIMENTAL OFFICERS (preferably biologists, but chemists or physicists with interest in biological research acceptable) at a Ministry of Supply Research Establishment near Salisbury—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting G.90/53A.

EXPERIMENTAL OFFICERS in R.A.F. Signals Establishments at (a) Ruislip, for general experimental work and tests in connexion with design of radio communications and radar systems, (b) Medmenham, for work on installation design of airfield communications and landing aid systems, equipment, investigations and siting problems, (c) Henlow (Assistant Experimental Officers only) for experimental work on calibration of transfer standards, involving bridge, frequency, and pulse measurements—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.90/53A.

LECTURER (Grade B) IN THE HYGIENE AND PUBLIC HEALTH DEPARTMENT—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W 11.

MECHANICAL ENGINEER or PHYSICIST (with first- or second-class honours degree or equivalent in mechanical engineering or physics) to undertake experimental and theoretical work with light mechanisms, at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.169/53A.

METALLURGIST or PHYSICAL CHEMIST (with university degree or equivalent qualification) to carry out research involving particular emphasis on vacuum melting of pure iron and special alloys (location of work: Sheffield)—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Vacuum Melting'.

RESEARCH ASSISTANT (with experience in algology, preferably with unicellular algæ) for work in biophysics IN THE DEPARTMENT OF BOTANY—Dr. R. D. Preston, Department of Botany, The University, Leeds 2.

RESEARCH ASSISTANT (with honours degree in engineering) for measurements for the elastic and plastic states for a metal-working process—Prof. Ford, Mechanical Engineering Department, City and Guilds College, Exhibition Road, London, S.W.7.

RESEARCH ASSISTANT (Inter.B.Sc. standard) for chemical investigations on the interaction of ink and paper—The Printing, Packaging and Allied Trades Research Association, Randalls Road, Leatherhead, quoting C.2.

# ACADEMIC FREEDOM AND THE UNORTHODOX

PROF. A. MACBEATH, of the Queen's University, Belfast, delivered an evening discourse to the British Association last September, putting forward a plea for 'heretics' as he termed them; and his thoughtful diagnosis of the contemporary situation has been published in *The Advancement of Science* (vol. 9, No. 35; December 1952) almost simultaneously with the delivery of Dr. J. B. Conant's last report as president of Harvard University, on his appointment as United States High Commissioner to Germany. In that report Dr. Conant likewise stoutly champions the right to dissent, and threw the full weight of his authority against any large inquiry in the McCarthy spirit into teaching systems and courses of instruction in colleges and universities. Dr. Conant himself believes that Communists should be banned from appointments in any school, college or university, and supports the discovery and prosecution of any subversives. He is not opposed to security investigations even in the academic world, provided it is conducted with "due process of law"—and Prof. W. Gellhorn and Mr. Alan Barth's books have provided sufficient evidence that many investigations have failed to observe this condition or to be conducted with the restraint that is necessary to avoid doing more harm than good. Nevertheless, said Dr. Conant, "It would be a sad day for the United States if the tradition of dissent were driven out of the universities. For it is the freedom to disagree, to quarrel with authority on intellectual matters, to think otherwise, that has made this nation what it is. . . . An industrial society was pioneered by men who were dissenters . . . the global struggle with communism turns on this very point. . . . The independence of each college and university would be threatened if Government agencies of any sort started inquiries into the nature of the instruction that was given. The colleges of the United States have nothing to hide, but their independence as corporate scholarly organizations is of supreme importance".

Dr. Conant thus stands with his fellow countrymen, Prof. G. Boas, of Johns Hopkins University, and Prof. H. S. Commager, of Columbia, whose warnings against the growth of authoritarianism and championship of the claims of criticism and dissent and non-conformity are quoted by Prof. Macbeath as evidence that the friends of freedom in the United States are alert and active. Indeed, the appointment of Dr. Conant himself as High Commissioner for Germany, in spite of his outspoken defence of academic freedom, suggests that his actions are not unwelcome to the American Government. The attack on nonconformity may continue in the United States and elsewhere; but it is at least clear that a widespread body of responsible men and women will not tolerate in silence and without resistance the development of the kind of society in which freedom of inquiry, criticism and originality do not flourish.

Prof. Macbeath began his discourse by reminding his audience that by the beginning of this century the freedom, which Milton with his sure insight recognized as the foundation of all other liberties and which is an essential condition of the advancement of science, seemed to be so thoroughly established that people tended to take it for granted as part of the natural order of things. To-day it is perhaps in greater danger than at any time since Milton wrote; and that dissent should be regarded as disloyalty, criticism as an unfriendly act, and difference of opinion as disaffection, show how far we have drifted towards authoritarianism and away from the free, frank and critical discussion of all questions which is the essence of democracy. Moreover, there are tendencies in the society which science has helped to produce which may slowly but surely destroy the spirit of free inquiry and produce a state of affairs in which science can no longer flourish.

The plea for 'heretics' was therefore essentially concerned with these factors in our contemporary society and with the causes which have produced them. Prof. Macbeath sees no evidence that the moral or intellectual qualities of our people have deteriorated. The conditions in which we live make greater demands on the intelligence, the imagination and the sympathy of our people, and as a result the people are bewildered, perplexed and unhappy. Although science has helped to produce it, this state of affairs is not an inevitable consequence of science or even of its application. Science has developed in the context of a society which provides its stimulus and inspiration and which provides the men who engage in it; and, rather than blame science, we should, if we wish to use wisely the power which science has placed at our disposal, seek to regain and retain our hold on the disintegrating factors in the situation.

This position must not be attributed merely to the wilfulness or wickedness of any group of men, and we cannot solve our problem by neglecting one half of life when we find reconciliation with the other difficult. Indeed, Prof. Macbeath laid his main stress on the need for sincerity—for acting on principles to which we are apt to render merely lip service. Much of the frustration and malaise in modern life are due to this discrepancy between our profession and our practice. If a principle is sound, the proper way is to act on it; to revitalize our society we need to reformulate the platitudes, to which we assent but in which we do not believe, and embody them in our institutions and way of life in such a manner that they would be true in theory and apply in practice.

The two most characteristic movements of the modern age, said Prof. Macbeath, are science and democracy. Both spring from respect for the dignity of man as an intelligent being. Both stand for what Plato called the victory of persuasion over force, of discussion over dictation, and both are tentative and experimental, rejecting all claims to dogmatic authority or certainty.

For three centuries men have been trying to embody their faith in this new attitude in institutions and a way of life. During the present century the presuppositions of both science and democracy have been challenged and they are called upon to defend themselves; this has been due mainly to technology and industrialism. It is these features of the modern age, he believes, which have produced the state of affairs threatening to destroy the scientific spirit to which they owe their origin.

In the modern world, science owes its prestige mainly to the power over his environment which i places at man's disposal. That power can be used for good or for evil, and when men found by bitte experience that it was not always wisely used, they reacted not only against freedom to misuse it but also against freedom in general. Such reaction is due at least in part to a confusion between science and the results of its application, and a consequent failure to distinguish between the freedom which is a necessary condition of scientific discovery and progress, and the control which has to be exercised over the use made of the results of applied science if they are to contribute to the welfare of man, and not to his undoing. It was also a confusion between what science does and what it does not profess to do which has led men to expect of science not only knowledge and power but also the wisdom to use it aright.

To these results must be added a natural resistance on the part of the ordinary man to the scientific attitude. It requires a long training and a hard discipline to eradicate the expectation that there exists a body of fixed and certain truth to be accepted as final, and to secure acceptance of the scientific viewpoint according to which all conclusions are on trial and the function of the mind is to be for ever reaching-out and for ever learning and testing Moreover, the scientific attitude is opposed to some of the settled tendencies of human nature, involving the co-operation of men of different classes and countries, in contrast to the relatively small groups to which many of our traditional, emotional and social habits and institutions have become adapted This resistance has also been greatly intensified by the changes which scientific techniques have introduced into the modern world. While science and democracy promise him a greater mastery and control over his environment, the individual man finds himself dependent and powerless. If he is to do anything, even to survive, he must join with others, and often on terms which are not of his choosing, while in large-scale organizations (industrial and political) fewer men than ever have the opportunity of exercising initiative, making responsible decisions, and guiding and controlling much even of their own behaviour.

Prof. Macbeath did not deny the need for such large-scale organization or for the planning inherent in it; but they constitute, he urged, a main threat to freedom to-day. They tend to ignore the distinction between persons and things; and a main problem of our time is to guard against this inherent tendency to tyranny on the part of administrators. They are liable to identify the plan which they wish to impose with the good of the community; then all dissent is regarded as disloyalty, all criticism as unreasonable and all objectors as traitors. Not only is the only safeguard against major mistakes then gone, but, equally important, there is the danger of inflexibility at a time when openmindedness and responsiveness to new ideas are more necessary than ver. Fixed ideas and habits to-day can be a public anger, and at best the time-lag between the technological changes and our habits and institutions auses a sense of tension and frustration in our ociety.

Such tension and frustration cause much unhappiness and division of loyalties in modern life. By ndermining its cohesion, they encourage also the endency to authoritarianism and the revolt against eason, and in such circumstances those who prefer ase to liberty are apt to be impatient and resentful of the dissenter or nonconformist who demands easons.

It is in such circumstances that Prof. Macbeath champions the right to dissent and the vital function of the heretic. Toleration, he maintains, is to be encouraged, not as an indulgence to error, but as a method of arriving at truth and as a safeguard against mistakes. Failure in tolerance is indeed evidence of an ultimate lack of faith in the soundness of our beliefs, in the value of our way of life and in the intelligence of our people; it is evidence of fear that they cannot withstand criticism. The function of the heretic and critic is to force us to keep examining and testing, revising and perfecting our beliefs and ideals. When that function is no longer permitted, stagnation will set in and freedom and science and all they stand for will decay and die.

In the last analysis, points out Prof. Macbeath, there are only two ways of dealing with human beings—the way of persuasion and the way of force. Science stands for the former and can only flourish n an atmosphere of freedom, an atmosphere in which dissent and nonconformity and difference of opinion are tolerated. That freedom is one and indivisible: if t is threatened anywhere, it is everywhere in danger.

To science the chief danger is probably, as Prof. Macbeath suggests, not so much from positive restrictions consciously imposed, as that the atmosphere of a society which rewards conformity and penalizes dissent may cease to produce scientists, men imbued with the spirit of free inquiry. Nevertheless, those positive restrictions are serious enough and Prof. Macbeath's noble plea should rouse scientists everywhere to action against whatever restrictions cannot be thoroughly justified on impartial inquiry. His diagnosis shows clearly the real danger that science may be crushed by its own creations, and that scientists cannot afford to remain silent.

Prof. Macbeath, in this address, has very forcibly put the argument for freedom as one factor in national security, and he does not deny the necessity for striking a balance between individual freedom and national security. That issue, however, he does not discuss, and it is complicated by the further conflict of loyalties to which he scarcely refers—and then more by the implication that our concern should be to foster the loyalties which so much in our modern world tends to erode.

There can be no question that the defence of freedom has been made more difficult in the past few years by the question of loyalty, and in particular by the claims of some scientists to determine such issues entirely for themselves. Here Prof. Macbeath gave much less guidance than Prof. A. V. Hill in his presidential address, nor can it be said that the Present Question Conference on Conflicts of Loyalties? held at Oxford during August 2–9, so far as reported in *Question**, touches the vital issues. Mr. H. Westmann's address on "Conflicts of Loyalties?" and Prof. M. Polanyi's on "Science and Faith" present some of the features of Prof. Macbeath's diagnosis and of the danger of an anti-scientific attitude being engendered. While indicating the need for clear thinking, they give little clue as to how on one hand the roots of loyalty—whether to science, to society or to mankind—are to be re-established or how, on the other, confidence can be engendered in the society in which the scientist works so that his work will not endanger its security and welfare.

Where that confidence has been undermined, however, it has been at least in part because the scientist or technologist has first betrayed his loyalty to his own particular scientific discipline or professional tradition. That is primarily a matter for professional or scientific associations, and if they are neglectful the harm can scarcely be corrected from outside, while the attempt to do so endangers the whole condition of creative scientific activity. On such issues Prof. Macbeath's address is first and foremost a challenge to professional bodies of scientific men, and unless they meet the challenge with courage and imagination the danger to scientific advance to which he points may well become even more acute; without courage there is no liberty. Scientific men must safeguard the highest standards of professional conduct, integrity and loyalty; but they must also ensure that due place is found for the dissenters and nonconformists, whose vision and independence contribute so much to the flexibility of mind and receptivity towards new ideas necessary for the advance of science.

## ECONOMICS OF THE PROTECTION OF PLANTS

Untaken Harvest

Man's Loss of Crops from Pest, Weed and Disease; an Introductory Study. By George Ordish. Pp. xii+171. (London: Constable and Co., Ltd., 1952.) 15s. net.

LOSSES caused by pests and diseases of plants have been expressed by many people in many ways. In this book, Mr. George Ordish maintains that such losses should not be calculated in terms of money or in terms of loss of yield but rather as a waste of land and labour. For example, if in the United Kingdom viruses are responsible for a loss of 10 per cent of the potato crop, the 7½ million ton yield represents only 90 per cent of the potential yield and the real loss is not the difference between 7·5 and 8·3 million tons "but the land, the labour and the resources used to grow these ungathered tons". The question that immediately arises is whether this method of representing losses can be successfully defended on biological grounds ? "Untaken Harvest" is a good selling title and rightly suggests some element of waste ; but is it good biology or indeed good natural philosophy to regard as an 'untaken harvest' the land, labour and resources used for growing 'ungathered tons' that exist only in the imagination ? Insects and fungi are part of the very complex community of living things ; were they to be removed, what would be the result ? Nobody knows, and nobody has yet grown an agricultural crop in the absence of insects and fungi. Though many biologists will not agree with Mr. Ordish's method of calculating losses, if they read this book they must agree that his case is very well argued and presented.

The book opens with a chapter on the pests and diseases themselves, in which there is also a brief résumé of control methods. Mr. Ordish then goes on to develop the main part of his thesis in Chapters 2 and 3 ; the losses caused by pests and diseases in many parts of the world are given, and their economic effects are described. The dangers and pitfalls awaiting the estimator of losses are discussed, and attention is directed to the lack of precise information and the need for more accurate figures and for better methods of assessing the losses. In spite of this, Mr. Ordish has in one table attempted to assess the losses by all the pests and all the diseases of all the crops in the United Kingdom. Let it be said at once that, *faute de mieux*, it is a brave attempt but lacking accurate figures ; one is inclined to pause and say with Pope, "Tis with our judgements as our watches, none go just alike, yet each believes his own". Unfortunately, when once figures of this nature have appeared in print, they are apt to be quoted *ad nauseam*, and other useful and more reliable figures in this book may lie neglected and forgotten.

In Chapter 3, which deals with the economic effects of the losses, Mr. Ordish is thoroughly at home, and the book is worth reading for this chapter alone. In estimating the relative efficiency of control measures, a ratio is established between the cost of the control and the potential benefit derived ; this is termed the cost/potential benefit ratio. The examples of such ratios given are worthy of careful study by the plant pathologist.

Chapter 4 deals with methods of combating the losses and the economics of the methods. These are well and fully discussed except that the credit for modern development in spray machinery appears to be very unevenly allocated. For example, no credit is assigned to the American forerunner of the auto-blast type of machine, and no mention is made of the excellent work of the Long Ashton Research Station in this field. On this subject Mr. Ordish has dealt only with a fragment of the literature, and, if a new edition is called for, opportunity ought to be taken to restore the balance. In this chapter, too, he says : "It seems to be generally agreed among a large number of entomologists that treatment from the air is not as effective as from the ground". Though many entomologists may agree, more than a few will disagree, and further careful comparisons of the two methods are badly needed.

The social effects of the losses are discussed in Chapter 5, and considerations on present and future crop protection in Chapter 6, wherein the economic of the various methods of plant protection are also discussed. The book concludes with a chapter on the trade in insecticides, fungicides and related products and there is an extremely useful table giving figure for world production and consumption of them.

Mr. Ordish, who is agricultural economist to Plant Protection, Ltd., has taken very great pains to read and collate an enormous amount of information which will be of great value to his colleagues in industry and to those who work in other spheres of applied biology. The emphasis could perhaps have been improved ; but as an economist Mr. Ordish has been able to see the problem in perspective. As an economist, however, he seems to have missed an opportunity of bringing other important factors into the picture—cultivations, fertilizers, breeding for increased yields, climatic factors, etc. Although reference is made to the fact that wheat yields have, during the past hundred years, risen from 26 to 36 bushels per acre, it is not made clear that some of this increase is due to better varieties, some to seed treatment, some to mechanization, but most is undoubtedly due to the increased use of fertilizers. How do losses from pests and diseases fit into this picture ? The answer to this question probably lies in closer co-operation between the soil chemist, nutrition chemist, plant pathologist, botanist, physiologist and all the rest of the scientific world that agriculture nowadays commands. I. THOMAS

## IDENTIFICATION OF COMMON WEEDS

### Common Farm Weeds Illustrated

By Plant Protection, Ltd. Pp. vii+172. (London: Butterworths Scientific Publications, Ltd., 1952.) 15s. net.

FARMERS and gardeners must eradicate weeds, and in order to do so with the maximum of efficiency it is desirable that the weeds should be speedily identified, especially if the use of weed-killers is contemplated. But a weed is only a plant which is growing where it either is not wanted or is doing actual harm, so to the pure botanist it is just another member of the plant kingdom (unless it has invaded his own garden).

Any good book on plants (including weeds), therefore, is of value to farmer and gardener as well as to botanist ; but the method of approach varies because the agriculturist and gardener seek to destroy, the botanist to study. So it is not surprising that the point of view also varies in that the farmer and the gardener fundamentally wish only to recognize the weed, no matter how, whereas the botanist treats the weed as a subject for scientific study. Perhaps, therefore, the botanist, especially the taxonomist, can be forgiven if he protests against the grouping of plants, no matter what they are, artificially according to colour of flower. This method is adopted here ; but, in view of the book's objective, the method is justified since quick recognition is all-important.

The book is divided into two sections : (1) arable weeds ; (2) grassland weeds. Following (1) is a list of grassland weeds also to be found on arable land ; following (2) is a list of weeds common to both arable land and grassland. Two facing pages are devoted to each plant. On the left-hand page is a large photograph of the plant in the juvenile stage; on the right, an adult plant is depicted. This is an ingenious method, for it will assist farmers and gardeners to catch their weeds in time. Below the two photographs are very simple descriptions using no technical terms. Here are described the plant itself, other popular names, general habit, shape of 'seed' and 'true' leaves, habitat, height, general appearance of flowers, habit of stems, and other points of recognition. Approximately eighty weeds are beautifully illustrated and well described.

The fact that the reviewer was able to go through the entire book in a matter of a few minutes, and, looking first at the right-hand pages, immediately recognized every adult plant, and, looking at the left-hand pages, recognized most of the juvenile plants, convinces him that the book will serve a very useful and important purpose for farmers and gardeners. Students of elementary botany will also find the book of considerable assistance in the identification of common plants.

L. J. F. Brimble

## THE PLACE OF DANCING IN RELIGION

### Religious Dances in the Christian Church and in Popular Medicine

By Prof. E. Louis Backman. Translated by E. Classen. Pp. xii+364. (London: George Allen and Unwin, Ltd., 1952.) 35s. net.

At all periods mankind has danced to get rid of surplus nervous emotion—to obtain release. During the First World War a United States hospital unit took over a British general hospital soon after the Germans had launched mustard-gas attacks. The sights and sounds were particularly distressing, and the nurses, new to war conditions, in many cases became hysterical, though doing their duties magnificently. When the matron organized dances, the nervous tension was released and the troubles ceased. It is only to be expected that, as dancing has this tension-relieving effect on a large number of people, it should appear in various forms in religious rites.

Even in prehistoric times, it would seem that dancing had a place in the various cults. Both in ancient Egypt and in Greece dancers are shown in the pictures of religious festivals; again, we read in the Old Testament how David danced before the Lord. Many other examples could be given. Naturally, then, when Europe became Christian, dancing was absorbed into the new cultus, though the Church naturally looked on it with disfavour, and from time to time attempts to exclude it were made. Nevertheless, it was not only the populace who frequently expressed their religious emotions by dancing; the clergy and choir, too, sometimes danced during the services. The Easter dances before the high altar in the cathedral at Seville are well known and still take place, and many less famous though equally ancient ones still happen in churches or churchyards at certain times of the year in many parts of the world, including England. It is true that nowadays these old rites are tending to disappear, but that is owing to the dull uniformity which is being imposed on mankind by modern conditions.

Prof. E. L. Backman, of the Royal University of Uppsala, has brought together a wealth of information on this subject, and the resulting volume is of great interest. The Church authorities in England were on the whole very averse to dancing becoming part of the cultus, and England has perhaps fewer examples to show than is the case on the Continent. Nevertheless, during Queen Elizabeth's reign men and women danced to the music of pipes and drums both inside churches and in the churchyards. I rather feel, too, that Prof. Backman might have mentioned the queer ritual dance which takes place yearly at Abbots Bromley in Staffordshire, where the participants carry reindeer antlers in front of their faces. It is true the dance is in all probability older than Christianity; but it has been so much Christianized that the antlers are kept in the church in the charge of the parson. Altogether, the book makes very good reading, and the translation would seem to be excellent.

M. C. Burkitt

## THE NEUROTIC IN SOCIETY

### Social Psychiatry

A Study of Therapeutic Communities. By Dr. Maxwell Jones, and A. Baker, Dr. Thomas Freeman, Julius Merry, B. A. Pomryn, Dr. Joseph Sandler, Joy Tuxford. Pp. xix+186. (London: Tavistock Publications, Ltd., in collaboration with Routledge and Kegan Paul, Ltd., 1952.) 18s. net.

Neurotic maladjustment is so prevalent and individual psychotherapy so prolonged that the psychiatrist has always sought more rapid methods of cure. During the Second World War, for example, physical treatments were pushed forward and patients subjected to insulin, prolonged narcosis and electrical convulsions. The 'cures' by these means have proved disappointing. Now the accent is on social psychiatry. This is the production of a special environment where the patient can adjust and find ways by which he can later take his place in society.

Dr. Maxwell Jones and his associates have written this book describing experiences in such communities: at Mill Hill, where an effort syndrome unit was established, at Dartford ex-prisoner of war hospital, and at Belmont Hospital for chronic neurotic unemployed. In these it was found impossible, owing to the numbers, to give individual psychotherapy, and lectures were discovered to be less useful than discussion groups where the patients were able to release their emotion. "Psycho-dramas" which are little plays, describing his own life, written by a patient were also found beneficial. Inmates do a four-hour day in industrial work, and are placed in industry by a resettlement officer when they are discharged. The results are claimed to be good; and six months after leaving hospital two-thirds of the patients have made a fair adjustment, or better, and one-third a poor or very poor adjustment. This is an interesting experiment, but one should reserve judgment until follow-up results for a longer period are published.

It is a pity when they have such interesting material that the authors have used such a repetitious and even slovenly style: for example, on p. 178 the old mistake of thinking that 'protagonist' means the opposite of 'antagonist' is made. The book records valuable facts on community life, and one looks forward to the publication of the final results later on.

Clifford Allen

# EXPERIMENTING AT HIGH PRESSURES*

By Prof. D. M. NEWITT, F.R.S., and K. E. BETT

Department of Chemical Engineering, Imperial College of Science and Technology, London

INVESTIGATIONS into the influence of pressure on the properties of matter are at present confined to limits prescribed by the mechanical properties of materials of construction. In plant designed to develop and sustain high internal pressures, two separate stress-systems have to be incorporated. The pressure is developed by an element of plant, usually a piston, in which there is under load an evenly distributed uniaxial compressive stress the magnitude of which is proportional to the pressure; and a portion of this element must be unsupported. Eventually the pressure has to be sustained by an enclosure, the walls of which are subjected to three principal stresses acting at right-angles to one another; two of these are tensile and one compressive. The important feature of this system is that the compressive stress and one of the tensile stresses are not uniformly distributed through the thickness of the walls, but have maximum values at the interior and diminish rapidly as the outer surface is approached.

A more uniform distribution of stresses under load can be achieved by making use of the property of work-hardening, as in the autofrettage process of cylinder construction; or by building a compound cylinder by the shrinkage process. In both cases it is necessary to know the distribution of the residual stresses and to develop means of stabilizing the residual system, so that no appreciable plastic flow will occur under working conditions. By making use of these processes and by providing external support for the vessel in such a way that the support increases proportionally to the internal pressure, it has been possible to construct plant in which pressures up to fifty thousand bars (a bar is approximately an atmosphere) can be maintained for considerable periods of time and pressures of the order of a hundred thousand bars for shorter periods. The energy stored in a material subjected to these stresses is made up of a work or potential energy component and a heat or kinetic component. Energy release may take place through either component separately or through a combination of the two, leading eventually to brittle fracture or plastic deformation.

It seems unlikely that these limits of pressure will be much exceeded with the materials and methods of construction at present available; and they are indeed sufficiently extensive to enable a comprehensive study to be made of those properties of matter which are associated with work done against the repulsive force fields of atoms and molecules.

There is, however, a second pressure domain of great interest to physicists, in which discontinuous transitions may be expected to take place by, for example, an overlap in the electron-phase space field of an atomic system. Calculations based upon quantum mechanical models place the lower limit of this domain at about one million bars; that is, far beyond any pressures at present attainable in the laboratory.

If attention is confined to the lower pressure domain, nearly every manifestation of pressure, whether chemical or physical, will require for its interpretation an accurate knowledge of at least three of the principal thermodynamic functions of the system, one of which, for obvious reasons, must be the pressure. A great deal of attention ought, therefore, to be paid to the accurate measurement of high pressure and to an assessment of the errors involved when the limits of practical working are approached.

Primary pressure gauges, of which the mercury column and the balanced free-piston gauge are examples, measure pressure in terms of fundamental units. They are, however, subject to restrictions imposed by the properties of the materials from which they are constructed and of the working fluid. Thus, in the case of the mercury column, the compressibility of mercury over the full range of the gauge has to be known; in the case of the free-piston gauge, the elastic and plastic deformation of the piston and cylinder assembly under the influence of pressure must be found, either by calculation or by direct measurement.

Suitably designed free-piston gauges will operate to about twelve thousand bars, but at this pressure they are relatively insensitive, due to the large frictional forces resulting from the increase in viscosity of the pressure-transmitting fluid. The area of the piston in such a gauge must of necessity be small, and direct measurement of the diameters of the piston and cylinder cannot be made with an accuracy sufficient to reduce the error of readings to less than 0·1 per cent. It is therefore necessary to obtain the effective piston area at low pressures by calibration against a mercury column or another free-piston gauge in which the diameter of the piston is large enough to be measured directly. At higher pressures, the piston and cylinder undergo deformation and the effective area, which is a function of pressure, has to be calculated from theories of elasticity. The error involved is uncertain, since the stresses arising from the efflux of liquid between the piston and cylinder cannot be measured directly.

In a free-piston gauge designed by P. W. Bridgman, the correction for elastic deformation was calculated to be 0·2 ± 0·05 per cent at 10,000 bars. Such a gauge will have an absolute accuracy of about 0·15 per cent, provided that its sensitivity is large compared with this figure.

A great deal of work at high pressures and, indeed, most of the work above ten thousand bars has been carried out with the aid of secondary gauges, of which the manganin gauge is the best known. Calibration of this gauge against a free-piston gauge shows that the response is a linear function of pressure to within the absolute accuracy of the primary gauge.

In order to extend the range of the manganin gauge to thirty thousand bars without the uncertainty of linear extrapolation, it is desirable to calibrate it against at least two fixed-pressure points. The lower point may be taken as the freezing pressure of mercury at 0° C., which is given by a free-piston gauge as 7,490 bars. The most suitable upper point is the I–II transition for pure bismuth, which at 30° C. takes place at 24,930 bars. This point has been measured directly by Bridgman using the method of volume discontinuity. In his apparatus, the pressure was transmitted to a specimen of the pure metal in direct contact with the piston, the distortion of the cylinder containing the specimen being determined experimentally. From measurements of the force transmitted to the piston and the area over which the piston acted, the pressure could be calculated. It is difficult to estimate the accuracy of the pressure measurement; but the total frictional effect obtained by measuring the transition point for both increasing and decreasing pressure was about 6 per cent.

---

* Summary of three lectures given by Prof. D. M. Newitt at the Royal Institution on January 27 and February 3 and 10.

By using the fixed pressure points, the change in resistance with pressure of manganin wire can be expressed as an equation of the second degree. Although the departure from linearity depends upon the history of the wire, experience shows that, in general, the deviation is only about 2 per cent at 25,000 bars. The gauge can be made very sensitive to small pressure-changes when used in conjunction with suitable electrical measuring apparatus; but it will be obvious that its accuracy depends almost entirely upon the absolute accuracy with which the fixed pressure points are known.

At pressures much above thirty thousand bars, all available pressure-transmitting liquids either become very viscous or freeze, and the manganin gauge can no longer be used. Pressures in this range have, therefore, to be measured directly, it being assumed that, in a thin specimen of material under pressure, stresses sufficiently close to hydrostatic conditions can be realized. Corrections for distortion of the apparatus have to be computed; and, since the material is often stressed beyond its normal elastic limit, no great accuracy can be claimed for the result. At pressures of 100,000 bars, the error is probably of the order of ± 10 per cent.

Thus it can be seen that the error involved in the measurement of pressure is a function of the pressure-range under consideration. Below twelve thousand bars, it is possible to increase the precision of a free-piston gauge by reducing the distortion of the piston and cylinder assembly; this can be accomplished by using the stronger materials of construction now available and by providing more effective external support for the cylinder. It is doubtful if the range of the gauge can be greatly extended, because the large increase in viscosity of pressure-transmitting fluid results in a serious loss of sensitivity. At pressures above thirty thousand bars, when all liquids have frozen, true hydrostatic conditions no longer exist and stress differences within the compressed solid of the order of its plastic shearing stress are to be expected. In this range, the error in the pressure measurement resulting from the variable frictional forces opposing the motion of a piston is greater than that due to the uncertainty in the distortion of the cylinder. Thus, any attempt to increase the accuracy of the measurements must be directed towards reducing the frictional forces. One method of doing this is to decrease the cross-sectional area of the material under compression; such a procedure, however, makes the accurate assessment of volume changes during compression very difficult, especially if the apparatus undergoes appreciable creep.

Although Bridgman measured the freezing pressure of mercury more than forty years ago, no accurate redetermination has been made since then. Indeed, the value has been accepted and used to calibrate various primary and secondary gauges, some of which have a greater sensitivity than the accuracy claimed by Bridgman for his original measurements. In view of the difficulties involved in the direct measurement of pressure, it would therefore seem desirable for the present to base all work upon an arbitrary standard scale of fixed pressure points which can be corrected from time to time as more accurate data become available.

---

# THE SOUTH ATLANTIC: LAND BRIDGES OR CONTINENTAL DRIFT?

THE proceedings of the symposium on "The Role of the South Atlantic Basin in Biogeography and Evolution", held by the Society for the Study of Evolution in New York during December 28–29, 1949, have now been handsomely published under the title of "The Problem of Land Connections across the South Atlantic, with Special Reference to the Mesozoic"*. Most of the contributions are remarkable—considering the speculative possibilities and heady enthusiasms inherent in the subject—for their scientific rigour, and several of them are of fundamental importance to everyone who is interested in the tangled complex of problems which come under discussion. These problems are essentially twofold: whether the southern continents received all their faunas and floras from the north or have been at times in direct contact with each other; and whether, if such contact existed, it was effected by land bridges or by contiguity, afterwards broken by continental drift. The chairman and editor, Dr. Ernst Mayr, points out that the symposium was organized, not to defend or disprove any particular hypothesis, but for the presentation and discussion of current evidence in one restricted but critical field of a much broader subject. In his conclusion he cheerfully admits that we are still confronted by many unsolved problems; but he claims with ample justification that the symposium has resulted in a much-needed correction of fact and clarification of concept. Dr. Mayr himself recalls the methodological principle that biological conclusions must be based on biological evidence, and geological conclusions on geological evidence. In particular, he directs the geologists' attention to the many pitfalls that lurk in biological interpretations—for example, in conclusions drawn from faulty classifications or from under-estimates of the dispersal powers of organisms over long periods of geological time.

Dr. G. G. Simpson's illuminating discussion of "Probabilities of Dispersal in Geologic Time" (pp. 163–176) is one of the high points of this invaluable publication. Simpson deflates many a speculative balloon by stressing the impossibility of inferring two simultaneous conclusions from what is actually known of the geographical distribution of a given group of organisms—namely, the land connexions of the time, and the probabilities of dispersal for the organisms concerned. To obtain a solution for either unknown,

* Bulletin of the American Museum of Natural History, Vol. 99, Article 3: The Problem of Land Connections across the South Atlantic, with Special Reference to the Mesozoic. (Proceedings of the Symposium on "The Role of the South Atlantic Basin in Biogeography and Evolution", held at the Fourth Annual Meeting of the Society for the Study of Evolution, New York City, December 28 and 29, 1949.) By E. Mayr (editor), M. Ewing, W. H. Bucher, K. E. Caster, C. O. Dunbar, M. Kay, G. G. Simpson, D. I. Axelrod, T. Just, W. H. Camp, P. J. Darlington, jun., A. E. Emerson, B. Schaeffer, D. H. Dunkle, E. H. Colbert and A. S. Romer. Pp. 79–258+2 plates. (New York: Amer. Mus. Nat. Hist., 1952.) 3 dollars

it is necessary to postulate either the existence (or absence) of land connexions or the probabilities of dispersal. Usually the latter postulate is made, the implication commonly being that $p$ is either 0 or 1. Simpson illustrates the very serious errors that may arise from confusing 'very low' with 'zero' and points out that estimates of probabilities, even when least subjective, may be wholly invalidated by the effect of geological time. Just as probability of dispersal is affected by the size of the population, so the passage of time multiplies the opportunities for dispersal. "If the probability that some member of a population will cross a barrier is ·000001 in any one year . . ., during the course of a million years the event would be probable, $p = \cdot 63$", and "in the course of 10 million years the event would become so extremely probable as to be, for most practical purposes, certain, $p = \cdot 99995$". Simpson concludes that evidences of random dispersals at scattered times indicate that probabilities of dispersal were so exceedingly low as to suggest the intervention of a major barrier. Ten years ago Simpson[1] directed attention to the relevant fact that, of the known Triassic reptiles of South America, only 43 per cent of the families and 8 per cent. of the genera are known in Africa, with no species in common. "These figures," he concluded, "are decidedly inconsistent with any direct union of corresponding parts of South America and Africa."

Among other general contributions, Dr. M. Ewing presents a useful summary (pp. 87–91) of geophysical evidence (up to 1950) and concludes that both seismic and gravity data show the great similarity of the Atlantic crustal structure to that of the Pacific, and their great dissimilarity to the continental crust. So far as such evidence goes, it is consistent with the hypothesis of the permanence of continents and ocean basins. But the Atlantic data are still too sparse to justify regional conclusions. Moreover, the discovery near the surface of crustal layers having the elastic properties of simatic rocks raises the question of what has happened to the many kilometres of sediment that must have accumulated over the original ocean floor, if the latter has existed for $\sim 3 \times 10^9$ years. Have they been deeply buried by repeated coverings of basic lavas and sills, and metamorphosed beyond seismic recognition ? If so, their radioactive contents might account for the unexpectedly high heat flow encountered through recently tested parts of the ocean floor. If not, then the seismic evidence recorded by Ewing could be interpreted as against the 'permanence' and 'land bridge' hypotheses and in favour of 'drift'.

Prof. W. H. Bucher sets out to deal with the general problems of "Continental Drift versus Land Bridges" (pp. 93–103), but his treatment is largely confined to the thesis that the topography, depressions, mountain ranges and structural relations of the ocean floor cannot be harmonized with Wegener's assumption that the simatic crust is or has been so weak that sialic bodies could drift through it. The criteria are not strictly so decisive as Bucher claims, since he fails to consider fully the effects of metamorphism and altogether ignores the hypothesis of sub-crustal convection currents ; nor does he even mention any of the evidence which favours the 'drift' hypothesis. Both Ewing and Bucher admit that vertical movements of considerable amplitude have demonstrably taken place, but Ewing limits the amplitude by the requirements of isostasy, while Bucher limits the area involved to that of a land bridge. Neither considers the possibility that the sub-crustal silicate mantle may not necessarily be as homogeneous in either space or time as theorists postulate. Localized changes of composition or phase, or of both, at depths below the so-called 'level of compensation' would adequately account for the vertical movements which seem so puzzling to geophysicists.

Turning to more specific evidence on South America and Africa, Prof. K. E. Caster gives an admirable and well-documented review (pp. 105–152) of the stratigraphical and palæontological data up to the end of the Mesozoic. Like others before him, he is so impressed by the Devonian–Triassic parallelism between the opposing lands that he favours a broad continental linkage up to the end of the Triassic. Nevertheless, he inadvertently raises a serious doubt as to the validity of what Dr. A. S. Romer (p. 253) calls "the strongest single piece of evidence for South American transatlantic connections". This is the occurrence of the supposedly freshwater reptile *Mesosaurus* in similar formations in South Africa and Brazil. Caster, however, records that *Mesosaurus* occurs in a fœtid limestone containing marine invertebrates, from which he infers that it was a nektonic animal inhabiting a seaway with a stagnant bottom. In a most stimulating discussion of Caster's paper, Prof. C. O. Dunbar makes the suggestion that, if *Mesosaurus* was thus adapted to a 'pelagic' life, it may well, like modern seals, have made long journeys to sea. In any event, it is improbable that migration could have been easy, since of the three African genera only one—and that of a different species—has been found in Brazil.

Another important point made by Dunbar is that, in the light of our present knowledge, the pre-Devonian record has no bearing whatsoever on the problem in hand. This is amply confirmed by recent work in dating the Pre-Cambrian. Caster states that the presence of *Collenia* "affords the best evidence to date for correlating strata in the oldest terranes on the two sides of the Atlantic basin". Unfortunately, the African occurrences to which he refers are in rocks which range in age from about six hundred million years to more than two thousand million years[2]. Dunbar also expresses the opinion that, until more is known about the reproduction of *Glossopteris* and its associates, it is scarcely necessary to drift continents or raise broad land-bridges to account for the distribution of this flora.

Prof. Marshall Kay also discusses stratigraphical evidence bearing on continental drift (pp. 159–162). His main point is to demonstrate from the distribution of Cambrian trilobites—on which weighty arguments have been based—that similarity of faunas does not in itself require close association later broken by 'drift'.

Dr. Mayr is satisfied (pp. 85 and 256) that there is no need to postulate former land connexions between South America and Africa to explain the distribution of mammals or birds, the available facts being "diametrically opposed to the possibility of such a connection". However, this clear-cut conclusion refers only to the late Mesozoic and Tertiary. For testing earlier connexions, fishes and reptiles are more suitable. Dr. E. H. Colbert reports fully on the Mesozoic reptiles (pp. 237–249). He thinks there may have been "a connection of sorts" during the mid-Triassic, but admits that no southern connexion would be essential if other evidence were forthcoming to prove that North and South America were then connected. The Jurassic evidence is inconclusive, while for the Cretaceous it is "rather unequivocally in favour of an active faunal interchange between South and North America". Discussing Colbert's paper, Dr. A. S. Romer (pp. 250–254) agrees about the Cretaceous and Jurassic but, although fully conscious that most hypothetical land bridges are not merely delusions but also snares to the unwary, he mildly disagrees about the Triassic. He writes: "I find myself here, after consideration of the evidence [which he carefully analyses] rather strongly inclined towards belief in the existence of a southern intercontinental connection between South America and South Africa in the Triassic. To my embarrassment; for in such a 'leftish' position I am disturbed . . . by the company (of bridge builders, radical continent shifters and Gondwanaland collectivists) which this may entail". Dr. B. Schaeffer reports on the fresh-water fishes (pp. 227–234), his conclusion—from what is admittedly a scanty record—being that there is no evidence of direct interchange between South America and Africa during any part of the Mesozoic.

In a most valuable paper on "Variables affecting the Probabilities of Dispersal in Geologic Time" (pp. 177–188), Prof. D. I. Axelrod illustrates his views with special reference to the effects of climatic and water barriers on angiosperm distribution. He claims that the continents have been in their present positions since the Middle Cretaceous and probably earlier: "The floras and the faunas, not the continents, have been moving during the past ages". Angiosperms, however, are not decisive for pre-Cretaceous times, and Dr. W. H. Camp's discussion of their phytophyletic patterns (pp. 205–212), though stimulating and suggestive, carries us no farther back. Dr. T. Just deals with the older and more critical fossil floras (pp. 189–204), but he finds the evidence insufficient for the drawing of firm conclusions.

In a brief survey (pp. 213–216) of living invertebrates in relation to Mesozoic South America, Dr. P. J. Darlington, jun., demolishes the idea that they provide any relevant evidence. In particular, he denies that paussids, which have been used as evidence of former land connexions, tell us anything significant about the history of South America. Prof. A. E. Emerson presents a highly original paper on "The Biogeography of Termites" (pp. 217–225) and reaches several tentative conclusions, the first being that "it is unnecessary to postulate any great change in continental masses and their connections since early Mesozoic times".

To end on a personal note: I should confess that, despite appearances to the contrary, I have never succeeded in freeing myself from a nagging prejudice against continental drift; in my geological bones, so to speak, I feel the hypothesis to be a fantastic one. But this is not science, and in reaction I have been deliberately careful not to ignore the very formidable body of evidence that has seemed to make continental drift an inescapable inference. In recent years the weight of evidence has become less oppressive, and this symposium has left me with the general impression that a few land bridges or linkages by island stepping-stones would probably suffice for the biogeographical problems. Matching of orogenic belts on opposing sides of the Atlantic is an exercise that has not been indulged in by the participants of this symposium. I have been collecting evidence from the Pre-Cambrian of South America, Africa[3] and India[4] for several years, and I think it is now safe to say that India cannot have been where Wegener placed it relative to Africa. The evidence on the other side, however, is still ambiguous. A remarkably good 'tectonic fit' between parts of South America and Africa can be recognized, but so far no correlation by age is possible, because the South American age determinations[5] have not been correlated with the tectonics and have not been checked by isotopic analyses. No doubt this temporary frustration will be overcome, and the matter will be decided one way or the other. At least we know how the problem can be settled.

Meanwhile, there remains the most serious enigma of all: the Permo-Carboniferous glaciations. Dunbar points out that the late Palæozoic glaciations in low latitudes present "a problem still unsolved, unless we accept continental drift". But if we accept continental drift only to explain these and other still older glaciations, it becomes no more than an *ad hoc* hypothesis. As such, it may still be justified as a stimulant to research, but it may also stand in the way of progress by distracting attention from the real problem. Can the meteorologists not come to our assistance and tell us whether or not widespread equatorial and low-latitude glaciation is possible while high latitudes for the most part enjoy a genial climate? The curious feature is that the evidence, so far as it goes, suggests that it was the distribution of ice in the Pleistocene that was exceptional, not the Permo-Carboniferous distribution. Southern Africa, in particular, was repeatedly glaciated during Pre-Cambrian times. While so many contradictory voices confuse judgment, one cannot do better than commend Dunbar's wise dictum that "it is unsafe to reject, *a priori*, either continental drift or foundering of broad land bridges". # THE FARADAY SOCIETY, 1903–53

## By DR. F. C. TOMPKINS

On February 14, 1903, a small meeting took place in the rooms of the now defunct Faraday Club at St. Ermin's Hotel, Westminster, and a new scientific society was inaugurated. A little later "The Faraday Society" was formally founded, having as its objects the promotion of "Electrochemistry, Electrometallurgy, Chemical Physics, and Kindred Subjects". The Society celebrated its fiftieth anniversary this year on April 16 at the Royal Institution, which houses the famous laboratories where Faraday's researches were carried out.

In 1903, as to-day, there were dangers, both financial and otherwise, in creating yet one more society and one more journal. Indeed, Sir William Ramsay viewed the prospects with marked disfavour, for he could not find sufficient time to read the stream of scientific literature already appearing. Despite this, the project made a good start under the presidency of Sir Joseph Swan, ably supported by such eminent men as Prof. Crum Brown, Prof. F. G. Donnan, Lord Kelvin, Sir Oliver Lodge, Dr. Ludwig Mond, Lord Rayleigh, Sir James Swinburne and others. Within a year there were 254 members, with

F. S. Spiers as honorary secretary and editor of the *Transactions*. To these men we must attribute the coining of the phrase 'chemical physics' to describe the borderline field between chemistry and physics. It is no contradiction that in April 1951 the objects of the Society were re-defined as follows: "to promote the Study of Sciences lying between Chemistry, Physics and Biology", for the founders had wisely included that indefinite phrase "and Kindred Subjects". The Society could, therefore, adjust itself as a living organism to its environment. At its inception, the *Transactions* fulfilled the need of a publication catering for developments in the study of metals, both in the more academic and in its technical aspects, as well as one for reporting those studies recognized to-day as the province of physical chemistry.

The first volume of the *Transactions* appeared in 1905; in its 366 pages there are thirty papers, and the path along which the Society was to travel was, even then, clearly defined. The contributions were grouped, usually in pairs, covering different aspects of a common topic. The reading of the papers was followed by a discussion, and the importance of having a permanent record of the comments and criticisms of other scientists was appreciated. The earlier volumes of the *Transactions* contain such a record and it remains a constant source of historical interest and value. The second object which has been carefully nurtured through the subsequent years was the encouragement given to scientists from overseas to present papers; thus we find that, of the thirty papers in the first volume, one originated in the United States and another in France.

The Faraday Society, unlike many other scientific societies, has never held regular meetings devoted to the reading of papers on unrelated topics; rather it has sought to find a new approach to the technique of scientific discussion. The Society can point to the success of its endeavours by reference to its own General Discussions, the hundredth of which is being held in this, its jubilee year. The first, on "Osmotic Pressure", was held in January 1907 in London, and since that time two or more have been held yearly. The purpose of such Discussions was clearly defined—to secure a survey of the topic under discussion from the varied points of view of scientists working along different lines of attack; to focus general interest in a subject with the object of extending its development or applications; to afford an opportunity of bringing forward new facts and theories for criticism and appreciation; and finally to map out possible new lines of investigation. The Society is justly proud of its General Discussions, for even in this era of conferences they still retain a unique character. It had been accepted that the important aspect was critical appraisal of a large proportion of the papers, and practically the whole time of the meeting is therefore devoted to this. All the papers are published in full in the form of preprints two or three weeks before the meeting, so that they may be studied at leisure. A high standard of criticism is consequently attained, and the recognition of the value and quality of the verbal discussion has resulted in authors setting themselves a high standard for their contributions.

The success of these meetings and the achievement of their objects depends primarily on the choice of subject and the timing of the Discussion. In the main, faith has been placed in the national characteristic of compromise—the programme, though limited and well defined in scope, is so arranged that it is of value and interest to the physicist, chemist, biologist, geologist, etc.—that is, to scientists of different disciplines and experiences who bring different points of view to the common theme, and so effect a cross-fertilization of ideas, a synthesis and a stimulus to originality. Moreover, overseas contributions are particularly invited in order to obtain a representative cross-section of authoritative scientists, irrespective of nationality. The Society has, indeed, been fortunate in obtaining their constant support in its endeavour to make these meetings truly international in character.

Looking back, say, twenty-five years, to the time when the theory of strong electrolytes represented a new powerful approach to replace the classical theory of dissociation, we need only turn the pages of the 1921 Discussion volume to illustrate this point. Britain was represented by papers from Bell, Hartley, Wolfenden and Wynne-Jones, while from overseas came such distinguished men as Bjerrum, Brønsted, Fajans, Harned, Huckel, Onsager and Scatchard, and written contributions were received from Debye, McInnes and Randall. Scarcely a name which would spring naturally to one's mind when considering this topic is absent; and how aptly was the time selected. The Debye–Hückel theory appeared in 1923 and Onsager's extension three years later, but their work was still hotly debated. It is no exaggeration to attribute the general acceptance of these theories and the opening up of the modern attack on the problem of short-range forces in solution to this meeting. Again, two years later, in 1929, the overseas members and guests who attended and contributed to the Bristol meeting on "Spectra in Relation to Molecular Structure" included Raman of India, Badger, Birge, Mulliken, Taylor, Wood and others from the United States, Bonnino from Italy, Victor Henri from Switzerland, Grimm, Herzberg, Hund, Schaefer from Germany, Errera from Belgium, and representatives of the best work from Canada, France, Poland and the U.S.S.R.—a veritable galaxy of stars. The Society has done much for the consolidation of theory, the co-ordination of different lines of approach and the stimulus to further work, by timing these Discussions to coincide with the upward surge of interest and of development.

It is dangerous—and often invidious—to pin-point any one contribution as being that from which a marked advance in knowledge and development of the many varied aspects of physical chemistry has evolved. But one may sometimes reflect that, had not a contribution appeared at that particular time, then the road of advance would indeed have been more arduous and the progress along it slower. It is of interest, therefore, to browse through the pages of old Discussion numbers to find whether they record such papers of especial significance.

In 1921, on the subject of chemical kinetics, there was the first suggestion by Lindemann (now Lord Cherwell) of the modern concept of the nature of unimolecular reactions; this led to the well-known Hinshelwood–Lindemann theory and sounded the approaching doom of the old radiation theory. But, almost as if it were in compensation, after the destructive criticism of an application of radiation theory in one Discussion, there appears in a later one a concept of major importance in guiding the spectroscopist and the photochemist in a memorable contribution by J. Franck containing the first enunciation of that broad generalization, the Franck–Condon

Principle. Again, although the Society cannot claim to have published the original concept of chain reactions, its first application to hydrocarbon reactions is given in the 1926 Discussion volume, on "Photochemical Reactions", in a contribution by this year's president, Prof. H. S. Taylor, of Princeton. At another meeting seven years later, Rice proposed his chain mechanism of the thermal cracking of hydrocarbons. Although this concept has now been modified and extended, it is difficult to assess the immense value of this one contribution to many industrial developments. As is always true of any outstanding advance in fundamental theory, its value grows when quantitative deductions are made possible. The recognition of the guiding principle—that of the stationary state—is clearly stated in a paper by the outstanding German chemist, Bodenstein, in the 1931 Discussion. Two years later, Paneth described the synthesis of the antimony analogue of Bunsen's cacodyl radical at a meeting of the Society, and in the same year there were the enunciation of the Franck–Rabinowitch effect and the detailed applications by Hückel and Lennard-Jones of quantum mechanical theories and the birth of the modern language of molecular orbitals and the like.

In quite different fields, the Discussion volumes record equally significant and important discoveries, each of which has largely affected our modern outlook; thus in 1930 Donnan applied to organisms his ionic membrane equilibria; a 1932 Discussion reports H. S. Taylor's concept of activated adsorption and the theoretical contributions of Lennard-Jones on the application of potential energy relationships to adsorption—and there are many more.

Although its publications contain the record of many such important advances in particular branches, yet the Society has never attempted to contract its wide field of interest. The whole of the region lying between physics, chemistry and biology is deemed its province, so that the range covered is possibly unsurpassed in scope and breadth in any similar series of publications. At first there was a bias towards the more technical and applied aspects, with Discussions on fluxes, slags, igneous rock formation, soils, refractories, cements, corrosion, electroplating, passivity and hardening of metals, to list only a few. The later publications are concerned with the more fundamental problems as exemplified by meetings devoted to kinetics, photochemistry, radiation chemistry, electrode processes, spectroscopy, molecular structure, adsorption, chromatography, solid reactions, dielectrics, luminescence, crystal growth, etc. In addition, the growth of colloid science has always been one of especial concern to the Faraday Society. More than any other single body it has been responsible for the development of, and interest in, this subject in Great Britain. Inspired by the enthusiasm of Sir William Hardy, this interest has been constantly maintained, particularly by the efforts of Sir Eric Rideal.

In 1934, the Colloid Committee of the Faraday Society was formed. Broadly conceived, with representation from other interested societies, it received generous help and guidance from the Council of the Society, and one General Discussion every two years was devoted to a subject of interest to colloid chemists. Using the organizing facilities of the Society and with its financial backing, the Colloid Committee went forward, and it is possible to trace the emergence and growth of colloid science in the publications of the Society. Again an initial trend towards aspects having technical value gave place to more fundamental problems; for Discussions on soils, textile materials and the like were followed by others on colloidal electrolytes, the electrical double layer, and the size and shape factor in colloidal systems. More recently, the Society has again taken a lead, this time in fostering the growing interest in biophysics. So long ago as 1930, a Discussion was held on "Colloid Science applied to Biology"; "The Properties and Functions of Membranes, Natural and Artificial" was one of the topics in 1937, and "Modes of Drug Action" in 1943. A pattern was slowly emerging and was thrown into relief in 1948 when the Society, always responsive to modern developments, decided to enlarge the scope and activity of the original Committee by reconstituting it as the Colloid and Biophysics Committee of the Faraday Society, and also to devote one Discussion yearly to topics of interest to that Committee. Such Discussions held over the past few years include "The Physical Chemistry of Proteins", "Lipo-proteins" and "The Optical Methods of Investigating Cell Structure". The Committee also initiates informal meetings on similar subjects of importance to biophysicists and colloid scientists, summaries of which are published in the *Transactions*.

Nevertheless, although the aims and objects of the Society can be well appreciated by a study of its Discussions volumes, the *Transactions* published monthly contribute no less vigorously to the life of the Society. It has been termed the foremost journal in Europe devoted solely to physical chemistry. Although only a hundred and fifty or so papers appear yearly, the lack of size is in part a measure of the high standard required of the contributions.

If the international character of the Discussion meetings is emphasized by the fact that 50 per cent of the papers may be contributed from overseas and that, of the audience of two to three hundred, eighty–ninety are resident outside Great Britain, then, although contributions to the *Transactions* are predominantly from the United Kingdom, yet some six hundred members out of the total of more than 2,200 are from outside the British Isles—some from the Dominions and Colonies, others from all the countries of Western, and some from Eastern, Europe, and many from the United States and the South American continent. On its fiftieth birthday, it is appropriate, therefore, that the president should be Dean H. S. Taylor, who for the past twenty years or more has done so much to enhance the reputation of Princeton University as one of the foremost schools of physical chemistry.

The Society has seen many changes: the original objects with their bias towards electrochemistry, metallography and metallurgy in its more technical aspects have changed, but its efforts in this field have not been unrewarded, because this interest has been taken over by what may be affectionately termed its daughter society, the Institute of Metal Finishing, formerly the Electrodepositors' Technical Society. There is no doubt that other similar changes and broadening of interests will be initiated in the future; perhaps the formation of further daughter societies encouraged by the expanding interests of science may be anticipated.

The Faraday Society has been well served by its members. Because of its generous benefactors, particularly Colonel J. J. Bourke, its financial problems, although not absent, are often less serious than are those of many other scientific bodies, and because of the enthusiasm of its first secretary, F. S. Spiers, whose name is perpetuated by the Spiers Memorial Lectures (the seventh of which will be delivered this year by Prof. J. H. Hildebrand), and of his successor, G. S. W. Marlow, the Society has never lost its initial impetus.

Its purpose remains to serve the changing needs of those interested in the sciences lying between chemistry, physics and biology, and to foster the international co-operation of scientists. Inspired by this purpose, a General Discussion on "The Reactivity of Free Radicals" was held last year in Canada at the University of Toronto. It proved a stimulating innovation; forty-five members travelled from Great Britain to meet in conference some eighty Canadians and sixty Americans. Those members will long remember their enthusiastic welcome in that great Dominion; they returned richer in knowledge and experience, with an increased appreciation of the high quality of the scientific contribution which Canada is making. The future may see this as the first of many Faraday Discussions to be held in other parts of the Commonwealth, the United States and Western Europe. The Society may hope thereby to contribute still further to "the glory of holding aloft among the nations the scientific name of England", to quote the words of Tyndall in appraising the genius of the man whose name the Society has been proud to assume.

# OBITUARIES

## Prof. J. W. McBain, F.R.S.

On March 12, one of the great pioneers in the field of what is now termed 'colloid science' passed away. The era of regarding colloids as an interesting field for those who desired to prepare chemical substances in curious and unexpected states was just beginning to pass when, as Leverhulme professor at the University of Bristol, James W. McBain commenced what proved to be his main interest in subsequent years at Leland Stanford University, California, namely, a systematic investigation of the properties of soaps and their solutions. We are indebted to McBain not only for the elucidation of the complex series of phases which these systems can exhibit but also for the concept of the 'micelle', both neutral and ionic, which had the most profound influence on subsequent developments in the fields of colloidal electrolytes. While the actual shape of the micelle in any particular system is still a matter of controversy, we may note that McBain recognized two distinct forms, the spherical and the lamellar. Indeed, he postulated the existence of the latter form, re-discovered in 1947, as early as 1925.

The contributions of the McBain school to the thermodynamic properties and physico-chemical behaviour of these molecularly associated colloidal electrolytes would alone justify the inclusion of his name among the fathers of the science.

McBain's researches in molecular association were not confined to aqueous systems. Apart from detailed studies on gels and jellies in non-aqueous systems, a great deal of pioneer work on what is now termed 'solubilization', for example, of water-insoluble dyes and hydrocarbons by means of soaps, has come from his laboratory; and we are indebted to him for an understanding of the factors operative in what he termed 'co-solvency', which is of great importance in blending.

McBain was one of the first to recognize that the uptake of a gas by a porous solid might involve quite a number of distinct and separate processes taking place simultaneously, and, to cover them all, introduced the term 'sorption'.

On the technical side we are indebted to McBain for many interesting and valuable research methods, such as the McBain sorption spring balance, the McBain air-driven centrifuge, as well as his ingenious methods of skimming off the Gibbs layer in a Langmuir trough, and evaluation of the osmotic coefficient by observations on the depression of the dew point.

McBain's contributions to colloid science consist not only in numerous papers to scientific journals; a number of valuable text-books have also emanated from his pen. These books are distinguished for their clarity of exposition, their style and their broadness in outlook on the topics under discussion. His last book, published in 1950, is designed to give the author's concept of the domain of colloid science. It is interesting to note that he does not limit the field to the properties of interfaces, but considers organization and form as equally important.

On retirement from Leland Stanford, McBain spent five years as director of the National Chemical Laboratory in India, a period which he completed only last year.

McBain had many friends, and he kept them. His character is most clearly revealed by his answer to the query put to him by the writer as to what impelled him to accept Pandit Nehru's offer of the Indian appointment. He replied that he was so impressed by the signs of starvation and low economy of many of the Indians that he thought it necessary for him to try to do something about it, and he believed that the infiltration of science and scientific methods was the only way by which anything radical could be accomplished.

Eric K. Rideal

## Father A. Gatterer, S.J.

Father Alois Gatterer, *S.J.*, who died on February 17, was a natural scientist of the best nineteenth-century tradition, student and teacher by turns throughout his career. Born of Austrian stock in 1886, he was educated in Carinthia and there entered the Society of Jesus at the age of nineteen to continue his studies in rhetoric, philosophy and theology. He was ordained as priest in 1915 and joined the staff of the faculty of theology in the University of Innsbruck; there he also studied chemistry and physics, graduated and was appointed to the staff. He was released from lecturing in philosophy in order to pursue his scientific studies. At the age of about forty he studied physics for a year at Oxford and developed an interest in spectroscopy, which he pursued on his return to Innsbruck.

In 1930, when he was forty-four, he was invited to join the staff of the Observatory at the Vatican, where he established and developed a spectroscopic laboratory, largely with the aim of analysing a valuable collection of meteorites bequeathed to the Observatory by a French mineralogist. This laboratory has gradually become excellently equipped, with the aid of grants from Pius XI and his successor.

One of Father Gatterer's first tasks was to purify carbon rods for electrodes: a new method of doing this was developed, and then early tests on meteorites showed up the weakness of the atlases of spectra then available. During 1937–49 one of the main tasks of his laboratory was the preparation of photographic atlases of the arc and spark spectra of iron, and then of the most useful lines of the remaining elements—a task which demonstrated Gatterer's endless patience and devotion to precision. These atlases are valued all over the world, and the last of them is one of the few subjects about which there is ever direct communication between Moscow and the Vatican.

In order to obtain pure iron for these reference spectra, pioneer work was done on the purification of iron; the method was eventually applied in an Austrian industrial laboratory in 1938. Another analytical problem which Father Gatterer helped to solve was the spectroscopic estimation of the halogens and of sulphur by the use of high-frequency discharges in vacuum to excite the spectrum. In 1938 Gatterer took the initiative in founding the international journal called *Spectrochimica Acta*, which was published in Germany by Springer, and which continued to appear with the names of its foreign editors on the cover until 1944. In 1947 Gatterer revived the journal and it was published from the Vatican Observatory for two years, after which it was returned to commercial production. Under Gatterer's editorship the printing received the same attention to detail as a spectrum gets.

Father Gatterer was a member of the Joint Commission on Spectroscopy of the International Astronomical Union and the International Union of Pure and Applied Physics; and he was delighted when that Commission and the International Astronomical Union both met in Rome last year, so that many of his friends could visit his laboratory.

Not only natural scientists but also industrial spectroscopists owe much to their contacts with Gatterer, who was an honorary member of national organizations of spectroscopists in both Italy and France. Manufacturers of spectrographs in both hemispheres benefited when he visited them to order apparatus to his own exacting specifications. From the age of twenty-six onwards he suffered from a series of painful illnesses, and he was partly crippled during most of these years. His cheerful fortitude under physical burdens and the humility underlying his devotion to truth made him an inspiring friend and teacher.

E. VAN SOMEREN

## Prof. P. Niggli

PROF. PAUL NIGGLI, who died recently in Zurich after only a few hours illness. was born on June 26, 1888. He had been director of the Mineralogical and Petrographical Institute of the Eidgenössische Technische Hochschule since 1920; and he had been also rector of the Highschool during 1929–32, and of the University of Zurich during 1940–42.

Paul Niggli graduated at the Eidgenossische Technische Hochschule in 1907 as an engineer, but he chose to make mineralogy his special subject and studied for a short time at Karlsruhe and later at the Geophysical Laboratory of the Carnegie Institution at Washington and published several papers with G. W. Morey. In 1914 he returned to Zurich, but later in the year he accepted a professorship in mineralogy and petrography at Leipzig and went to Tübingen in a similar capacity in 1918. On Grubenmann's retirement, Niggli was called to succeed him as professor at Zurich in 1920, and there then began the building up of an institute renowned for the high standard of its teaching and research. He was assisted there by a devoted team of able professors and assistants. Germany made one attempt to lure him back to take the chair of mineralogy and petrography at Charlottenburg, but Niggli decided to remain at Zurich, to the great delight of staff and students, who celebrated the occasion by a torchlight procession in his honour.

Niggli was a man of great ability, wide knowledge, and immense industry. His masters at Zurich were Albert Heim and Grubenmann, and his earliest published works as a student were on the chloritoid schists of the Gotthard massif and a geological map of Zofingen, his own birthplace. A list of his very numerous books and papers was published in the "Festschrift" issued in honour of his sixtieth birthday in 1948. He ranged over the whole field of crystallography, mineralogy and petrography, and sought especially to expound the principles of physical chemistry that apply to the paragenesis of minerals and the differentiation processes and metamorphism of rocks. In his "Geometrische Kristallographie des Diskontinuums" (Leipzig, 1918–19), he brought up to date Schoenflies's "Krystallsysteme und Krystallstruktur" (1891), introducing the new work based on X-ray analysis. This was followed by many papers and chapters in his "Lehrbuch", and others on crystal structure and stereochemistry. He was an editor of the *Zeitschrift für Kristallographie* during 1920–40.

His "Lehrbuch" (Berlin, 1920) ran to three editions; but each 'edition' was really a different book presenting various parts of the subject of crystallography and mineralogy from new angles and in the light of new knowledge. Unfortunately, Part 3 of the third edition, written in 1944 and set up in type, was twice destroyed in Berlin during the War, and Niggli had not the heart to write it again.

Petrology and the working out of methods of handling and studying the mass of chemical data available on igneous and metamorphic rocks, and the application of physical chemical principles and phase rule to the problems, figured largely in his work at Zurich. He collaborated with Grubenmann in a new book on metamorphism (1924) and with Burri in a vast survey of the mineral-chemical characters of the younger eruptive rocks of the Mediterranean orogeny, covering, in fact, a region stretching from America eastwards to the western shores of the Pacific. This work, in which more than two thousand chemical analyses were handled, used to the full Niggli's method of recalculating analyses in 'Niggli values', a method which, together with his later system of molecular norms and his graphical methods for comparing and exhibiting chemical characters of rocks, have all had considerable influence on petrography throughout the world.

Niggli was somewhat reserved in manner, especially in later years. Much of his writing was in rather difficult German, and he rarely wrote in English although he spoke it fluently. His great ability received world-wide recognition. He received honorary doctorates from the Universities of Stuttgart, Budapest, Liège and Sofia; he was given the Hayden Award of the Philadelphia Academy of Natural Science, the Roebling Medal of the Mineralogical Society of America, and the Orville Derby Medal (Rio de Janeiro), 1952. As a corresponding or honorary member he had been elected to no less than twenty-seven academies and societies, including the Geological Society of London and the Mineralogical Society, of which he was the senior honorary member, having been elected in 1933.

W. CAMPBELL SMITH

# NEWS and VIEWS

## National Physical Laboratory Standards of Radioactive Isotopes

Dr. E. C. Bullard, director of the National Physical Laboratory, has issued the following announcement: "The National Physical Laboratory has at present the main responsibility for standards of certain radioactive isotopes in Great Britain. It is proposing to issue standards of these isotopes at regular intervals to meet the needs of those whose use of such materials justifies absolute standards and to supplement the normal calibrations which can be obtained on request from the Atomic Energy Research Establishment, Harwell. Standards of iodine-131, based on the British Standard (see *Nature*, 170, 916; 1952) for this isotope, will be issued on or about October 15, 1953. Future issues will take place twice-yearly in mid-April and mid-October. The iodine-131 standards will be in the form of sealed ampoules of solution. Two different levels of activity will be available, one of 1 millicurie in 1 ml. of solution and one of 100 microcuries in 4 ml. of solution. Issues of standards of phosphorus-32 (100 microcuries in 4 ml. of solution) are planned to take place on June 15 and December 1, 1953. Applications for these standards should reach the National Physical Laboratory not later than a fortnight before the appropriate date of issue, and should include a statement of the purposes for which the standards are required. A fee of £10 will be charged for each 1-millicurie standard and of £5 for each 100-microcurie standard. It is requested that applicants should make their own arrangements for the collection of their standards from the Laboratory. An announcement relating to the issue of cobalt-60 standards will be made in the near future."

## Research in Coal Mining: Dr. L. C. Tyte

The National Coal Board has appointed Dr. L. C. Tyte to be director of its second Central Research Establishment at Isleworth, Middlesex, which is engaged on investigations of the underground problems of the industry. Dr. Tyte will be responsible to the Director-General of Research, Dr. W. Idris Jones, at headquarters. Dr. Tyte, who is forty-six, was educated at Queen Mary College, University of London, where he carried out research under Prof. C. H. Lees. Later he joined the Government Scientific Service at the Research Department at Woolwich Arsenal and latterly has been engaged on projectile research. He was promoted deputy chief scientific officer in 1950 and was technical director under Sir William Penney at the Monte Bello trial.

## Wigan and District Mining and Technical College

The Wigan and District Mining and Technical College, now in its ninety-sixth session, celebrated Founders' Day for the first time for fifteen years on March 25, when Sir Hubert Houldsworth, chairman of the National Coal Board, was the chief speaker. Sir Hubert, who paid tribute to the work of the College in providing leaders in many industries, referred to the scholarship scheme of the National Coal Board. Although Great Britain is suffering, among other things, from an insufficiency of qualified technical men, the Board is unable to find sufficient candidates for its hundred scholarships each year, although those selected have done well. Sir Hubert referred in particular to the desirability of more applications from those leaving school with a leaning towards physics, chemistry, mathematics and geology. Although many of the key positions in the industry are filled to-day by those who had no previous connexion with mining, he believes that a restricted mentality towards mining in schools outside the mining areas may be hindering recruitment. Emphasizing the need for attracting more men and the opportunity for those who have had their scientific—and preliminary—training at such a college or at a university, Sir Hubert welcomed the contribution of the Wigan Mining College to training for leadership for other industries. More than technical skill is required if the efficiency of the mining industry, or others, is to be raised and the lag between discovery or invention and application to practical purposes reduced. Besides technical knowledge, integrity, boldness in conception and soundness in judgment, leadership in industry demands interest in and understanding of human beings. Sir Hubert also stressed the importance of watching for originality and seeing that it is given full scope, particularly in research, and concluded by stressing the need for inculcating a spirit of service to the whole community.

In his report as principal, Dr. E. C. Smith said that, since Founders' Day was last celebrated, the number of students has increased from about 1,800 to some 3,000. Evening students have tended to decrease in numbers; but those attending on part-time day release have increased continuously from 220 in 1938 to 1,200. Such co-operation is specially marked with the National Coal Board. Full-time students have increased from 155 to more than 400. Dr. Smith referred to the extent to which the College has supplied training in technical teaching and administration to those who have since become heads of technical colleges or departments elsewhere, and stated that more officials of the National Coal Board have been trained at Wigan than at any other technical college or university in the country. The College library provides a first-rate service not only for the staff and students of the College, but also for research workers within the field covered, and the Manchester Geological and Mining Society now has its headquarters at the College.

## Technical Resources of Industrial Firms

In reply to a question in the House of Commons on March 31, Mr. A. H. E. Molson, Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, stated that the Manchester Joint Research Council's survey of the technical resources of industrial firms is complete, and that the Council is preparing a report for possible publication. The Department of Engineering Production in the University of Birmingham is continuing its survey under a research contract with the Department of Scientific and Industrial Research. A pilot survey of the technical resources of industrial firms in two small selected areas has been carried out by the Social Survey; but it is not proposed to publish a report of this survey. Mr. Molson added that the Department of Scientific and Industrial Research is considering the preparation of a general paper covering all three surveys.

## Scientific Instruments of George III

A collection of more than three hundred and fifty scientific instruments and pieces of apparatus was made for the instruction of George III (1738–1820), when a youth, and was afterwards used for the education of his children. From 1769 onwards, these instruments were housed at the King's private observatory at Richmond, Surrey, a building now known as Kew Observatory. In 1841 they were presented to King's College, London, where they remained until they were transferred on loan to the Science Museum, London, S.W.7, in 1926. The collection has been on view to the public on only two previous occasions, namely, for short periods in 1928 and 1949, and the recent completion of the first stage of the rebuilding plan for the Science Museum now makes it possible for approximately one-half of this collection to be placed on permanent exhibition in one of the reconstructed galleries. The instruments, the majority of which were acquired between 1740 and 1768, cover the field of study known, in the eighteenth century, by the title of 'experimental philosophy'; although the collection is particularly rich in material designed for experiments in mechanics, pneumatics and electricity, numerous examples are also included of instruments used in astronomy, optics, surveying, magnetism, acoustics, chemistry and heat. The collection thus affords not only a valuable display of the type of science being taught during an important era in scientific development, but it also provides a fine example of the skill and craftsmanship of the scientific instrument maker of the period. A descriptive catalogue of the complete collection is now available from the Science Museum (price 7*s.* 6*d.*), and there is also a guide book (price 6*d.*) which gives a brief outline of the history of the collection, together with notes about some of the more important scientific instruments represented in the exhibition.

## Bibliography of Geiger–Müller Counters

A SHORT but useful bibliography of articles that have appeared during 1931–50, inclusive, on Geiger–Müller photon counters has been compiled by J. E. Walker, of the Electronics Division of the United States National Bureau of Standards (Report 1050; pp. 16; Washington, D.C.: Nat. Bur. Stand., 1952). Eighty-one papers or books, arranged in alphabetical order of authors, are listed. Most of the papers in English and German have been included, but only a selection of those in French, Russian and Italian; and it is a pity that no attempt was made to make the bibliography complete. Each reference is followed by either the author's abstract or comments by Mr. Walker. Those of historical interest only are dealt with very briefly.

## Oil Exhibition at the City Museum, Bristol

A SCIENTIFIC and technical oil exhibition, designed expressly for a museum public, is now on view in the City Museum, Bristol, until May 2, prior to touring other provincial museums. Developed by the Shell Petroleum Co., Ltd., the exhibition aims both at attracting and educating, and is readily understandable without the need for accompanying lectures or explanatory talks. Starting with the origin of oil, the exhibition goes on to deal with exploration, drilling and the development of oil fields and with the different means of transport; the chain of events from refining, manufacture and research to the distribution of products to consumers is also outlined. The whole arrangement is made up of twenty-two portable display cases, one or more of which are devoted to each of the fifteen subjects into which the activities of the industry have been divided. The treatment of the displays differs: some include models, reliefs or dioramas; others are purely photographic, with pictures of artistic merit as well as of technical interest. Each display is labelled, and there is a descriptive leaflet available to visitors.

## Flora and Fauna of South Carolina

THE first number of *University of South Carolina Publications: Series 3, Biology*, has recently been published (1, No. 1; pp. 41; 1952; from the University, Columbia, S.C.; 75 cents). This is a new journal that is to be devoted to taxonomic studies of the flora and fauna of the State of South Carolina. It is published by the Research Committee of the University at irregular intervals as the material is available, and the first number consists of two contributions, the first of which, by J. T. Penny, is on the amphibians and reptiles of the State. Of the amphibians, fifty-five species with eleven sub-species are listed and, of the reptiles, fifty-nine species and fifteen sub-species, which gives an idea of the richness of this fauna in South Carolina. In each instance the type locality of the form is given. The second paper, by Harry W. Freeman, on the "Fishes of Richland County", is based upon a collection from thirty-seven localities, all listed, and reports forty-nine species and one specimen considered as a hybrid. Up to the time of this collection only eighteen species had been recorded, and the author obtained thirteen of these, so that the total number of species recorded from the county is fifty-four. Both papers start with a short historical introduction, a point to be commended; the first reptile to be recorded was the alligator in 1682, but the first serious beginning was Catesby's classical "Natural History of Carolina, Florida and Bahama Islands" (1730–48). Both papers also conclude with a complete bibliography. The printing, paper and layout are very satisfactory.

## First International Polarographic Congress, Prague

THE third volume of the proceedings of the First International Polarographic Congress, held in Prague during February 1951, has now been published (pp. 774; from Orbis-Export, 30 Ve Smeckach, Prague II; 10.80 dollars). The volume contains eight reports on the field of modern polarography, including its applications in chemical analysis, biochemistry and medicine, and these are followed by fifty-six contributions to the Congress, with discussions. The text is in Czech, with versions in Russian and extensively in English and German. This adds considerably to the bulk of the volume, but will be appreciated by readers not familiar with the first two languages. The volume is impressive as showing the great advances made in the important subject of polarography, and should be found of considerable interest.

## Second International Congress on Rheology, Oxford

THE detailed programme of the Second International Congress on Rheology (see *Nature*, 170, 487; 1952), to be held in Oxford during July 26–31, has now been published. The address by the president of the Congress, Sir Geoffrey Taylor, will be on "Rheology for Mathematicians", and other general lectures will be given as follows: on the electroviscous effect (in French), by Mme. A. Dobry Duclaux (Paris); rheological problems in the fabrication of plastics, by R. S. Spencer (Midland, Mich.); rheology and applied mechanics, by R. N. J. Saal (Amsterdam); rheological behaviour and the molecular jumping mechanism, by F. H. Müller (Marburg); water association and hydrogels, by E. Forslind (Stockholm); and biological problems for the rheologist, by P. Eggleton (Edinburgh). The other papers in the programme will be read at one of the three sections of the Congress; it is noteworthy that a number of the authors of these papers come from countries other than Great Britain, namely, Brazil, France, Germany, Holland, Sweden, United States and Yugoslavia. The Congress fee is £4, which includes preprints of all the papers to be read; orders for additional copies of the proceedings and for off-print copies of individual papers should be addressed to the publishers, Butterworths Publications, Ltd., 436 Strand, London, W.C.2. Application forms for the Congress (to be returned by May 1) and further details can be obtained from the honorary organizing secretary, Dr. G. W. Scott-Blair, University of Reading.

## Oxidation of Oils and Fats: Symposium in Cambridge

A symposium on the oxidation of oils and fats will be held by the Oils and Fats Group of the Society of Chemical Industry on April 24 at the Low Temperature Research Station, Downing Street, Cambridge. Prof. C. E. H. Bawn will give an introductory address, and he will be followed by talks on recent research, as follows: Dr. C. H. Lea, on oxidative deterioration of lipids; Dr. A. Banks, on autoxidation of linoleic acid; Dr. L. A. O'Neill, on autoxidation of drying oils; and Dr. J. H. Skellon, on oxidation of monoethenoid fatty acids and esters. Further information can be obtained from the General Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

## Chemical Society: Officers

Officers of the Chemical Society have been elected as follows: *President*, Prof. C. K. Ingold; *Vice-Presidents*, Prof. F. G. Donnan, Sir Ian Heilbron, Sir Cyril Hinshelwood, Dr. W. H. Mills, Sir Eric Rideal, Sir Robert Robinson, Prof. G. R. Clemo, Prof. R. D. Haworth, Prof. D. H. Hey, Prof. E. L. Hirst, Sir John Simonsen and Prof. M. Stacey; *Treasurer*, Sir Wallace Akers; *Secretaries*, Prof. H. Burton, Prof. E. D. Hughes and Dr. L. E. Sutton; *New Members of Council*, Prof. F. Bergel, Prof. M. J. S. Dewar, Dr. I. J. Faulkner, Prof. Brynmor Jones and Dr. A. I. Vogel.

## Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: D. F. Phillips (agricultural assistant, Tanganyika), agricultural officer, Tanganyika; F. A. Rabagliati (assistant agricultural officer, Kenya), agricultural officer, Kenya; B. J. Silk (agricultural education officer, Gold Coast), senior agricultural education officer, Gold Coast; F. Durocher-Yvon (director of agriculture, Seychelles), agricultural officer, Northern Rhodesia; S. J. Curry (entomologist, Cyprus), entomologist, Kenya; Major the Hon. P. L. A. O'Brien (geologist, Northern Rhodesia), senior geologist, Northern Rhodesia; Gunn Lay Teik (chemist, Agricultural Department, Federation of Malaya), senior chemist, Agricultural Department, Federation of Malaya; D. F. Laing and F. E. Trevitt, veterinary officers, Nigeria; B. McCulloch, veterinary research officer, Tanganyika; R. Blower, soil conservation officer, Kenya; C. Bos, arrowroot processing chemist, Windward Islands; T. D. Rees, geochemist, Geological Survey Department, Tanganyika.

## Announcements

The Royal Astronomical Society has elected Prof. V. A. Ambartsumian, of the University Observatory, Leningrad, and Prof. A. Unsöld, of the University Observatory, Kiel, to be associates.

Dr. Detlev W. Bronk, president of the Johns Hopkins University and president of the United States National Academy of Sciences, has been elected by the Paris Academy of Sciences to be a *correspondant* for the Divisions of Free Academicians and of the Application of Science to Industry in succession to the late Prof. F. Marguet.

Mr. J. A. Ratcliffe, of the Cavendish Laboratory, Cambridge, has been awarded the Holweck Medal and Prize for 1953 and will deliver the eighth Holweck Lecture in Paris on May 22; his subject will be "Some Aspects of Diffraction Theory". The Holweck Medal was founded by the Physical Society as a memorial to Fernand Holweck, director of the Radium Institute, Paris, and to other French physicists who were killed during the occupation of France in the Second World War, and the award is made annually by the Physical Society and the Société Française de Physique jointly. The recipient is alternately a French and a British physicist, distinguished for his work in experimental physics.

The Television Society's Silver Medal has been awarded for 1953 to Mr. George Cansdale, for his feature on the B.B.C. television programme in presenting animals from the London Zoo. This Medal, which was instituted in 1948, is intended to acknowledge the work done by an author, actor, producer, or any member of the television service in promoting the artistic or entertainment side of television programmes; and, in making the award this year, the Society has recognized that the function of television is not only entertainment but also education, both of which are combined in Mr. Cansdale's programmes.

The James Cook Medal for 1952 of the Royal Society of New South Wales has been awarded to Emeritus Prof. W. L. Waterhouse, of the University of Sydney, in recognition of his work in the field of agricultural science, particularly in the breeding of rust-resistant wheats. The James Cook Medal is awarded for "outstanding contributions to Science and Human Welfare in and for the Southern Hemisphere". The first award was made to Field-Marshal J. C. Smuts a short time before his death in 1950.

Dr. G. P. Contractor, who for the past three years has been the acting director of the National Metallurgical Laboratory of India, Tatanagar, of the Indian Council of Scientific and Industrial Research, has recently resigned from the Council.

Dr. C. J. Stubblefield, chief palæontologist since 1947 of the Geological Survey of Great Britain, has been appointed assistant director of the Survey and curator of the Museum of Practical Geology, London.

The following have been appointed to readerships tenable at St. Mary's Hospital Medical School, London: Mr. A. d'A. Bellairs (anatomy) and Dr. K. W. Cross (human physiology). The title of reader has been conferred on the following in respect of the posts held by them at University College, London: Dr. J. T. Aitken (anatomy) and Dr. G. E. Fogg (botany).

# PETROLEUM CHEMICALS INDUSTRY IN GREAT BRITAIN

UNDER the joint auspices of the Society of Chemical Industry (London Section) and the Institute of Petroleum, a full day was devoted to a symposium on the "Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry", which was held on March 2 at the Institution of Electrical Engineers, Savoy Place, London. Twelve papers, previously circulated, were briefly outlined by their authors, and discussion followed. The questioning was direct, though an understandable desire of industrial firms to retain their trade secrets led on occasion to reticence in giving equally direct replies. Throughout, the discussion was spirited; the wide range of subjects considered led, not to a diffusion of interest, but to a shaping and crystallization of views that was informative and helpful.

In opening the symposium, Mr. E. J. Dunstan (Manchester Oil Refinery, Ltd.) compared the earlier development of the petroleum chemicals industry in the United States with the growing British effort in this field. The natural conservatism in Britain of old-established industries and the inability of industrial organizations to pay for development projects out of earnings have impeded that growth and proliferation which are essential if the chemical industry is to make an adequate contribution to the well-being of the people and to the balance of trade. After making due allowance for the different economic climates of the United States and Great Britain and the industrial and commercial requirements and trends peculiar to the latter country which may invalidate arguments based on simple analogy, Mr. Dunstan concluded that the British petroleum chemicals industry requires substantial additional resources of capital, an increased intake of technically trained men (particularly chemical engineers) and the full collaboration of labour; otherwise its energetic beginnings which promised so much may die away, and the opportunities that this young industry offers for strengthening the national economy may well be lost.

This theme of the economic effect of the industry on our trading position was elaborated by Dr. R. F Goldstein (British Oxygen Co., Ltd.). The chemical industry as a whole has increased its production capacity since 1948 from £327 to nearly £500 million—an increase which compares very favourably with the expansion-rate of other industries in Great Britain and with that of the chemical industry in other European countries. To this increase, the petroleum chemicals industry has made a substantial contribution, at the cost of capital investment in the region of £40–50 million. If the British industry were to continue to grow at the same proportionate rate as the United States petroleum chemicals industry is expected to develop, according to the Paley Report, during the next twenty-five years, then additional capital investment at the rate of £14 million a year would be required, and the whole chemical industry would demand about £70 million a year for comparable expansion. The threat of capital starvation of the industry is real, and the hope of survival lies in the probability that the profit record of the chemical industry as a whole will prove a sufficiently strong attraction to new risk capital.

The technical basis of the industry was outlined by Dr. H. K. Whalley (British Industrial Solvents, Ltd.). Oil refining offers a range of raw materials extending from methane (which may be used for the production of synthesis gas, acetylene, hydrocyanic acid, etc.), ethylene, ethane, $C_3$s and $C_4$s, to the light distillates such as naphtha, kerosine and gas oil, which are the feed stocks for cracking processes specially developed for making olefines and aromatics for subsequent chemical conversion. Oil-refining processes such as thermal and catalytic reforming and thermal and catalytic cracking, which are designed primarily to give increased quantities of high-quality gasoline, also yield gases as by-products which serve as starting materials for the petroleum chemicals industry. Further, catalytic reforming processes developed by the oil industry for the octane-number improvement of gasoline and naphtha may be adapted for aromatics production. The conventional oil-refining industry is therefore making a dual contribution to the development of petroleum chemicals: it provides the charge stocks from which the essential olefines and aromatics may be made, and it aids the technological growth of the new industry by its own research, development and experience in cracking, alkylation, reforming and polymerization processes. These ties between petroleum refining and petroleum chemicals production are not restrictive: mutual benefits, both technical and economic, must come from the closest association of the two industries.

Two aspects of plant design and construction were dealt with by Mr. E. Smith (Firth-Vickers Stainless Steels, Ltd.) and Mr. E. O. Curtiss (The Lummus Co., Ltd.). The dangers of intergranular corrosion of unstabilized 18/8 austenitic steels, due to deposition of chromium carbide at grain boundaries, was strongly emphasized. Ordinary 18/8 steel, when reheated to 500–800° C., is rendered susceptible to this defect, but the risk can be eliminated if titanium or niobium is added to the steel. Though full details of a wide range of corrosion- and heat-resisting steels were given, Mr. Smith stressed the desirability of designers, fabricators and users consulting with steel manufacturers, so that the needs of each particular job could be more satisfactorily met.

Some problems in the design of plants for the recovery of light olefines from refinery and cracker gases were described by Mr. Curtiss, with emphasis on the absorption–fractionation method. The preliminary removal of sulphur and acetylene, followed by drying of the gas stream, was outlined, and the design and operation of the absorption–fractionation system were described in detail. The alternative process relying on low-temperature distillation and cascade refrigeration systems was also discussed, and the point was made that the relative merits of the two processes are dependent upon the nature of the feed stock and the required recoveries and purities of the product gas streams. In discussion, Mr. Curtiss observed that the hypersorption process, which relies upon the adsorption of gases by charcoal and their selective desorption, is less widely used, and the reason may lie in the difficulties in stripping the adsorbent and in its attrition.

The synthesis of ethyl alcohol by the catalytic hydration of ethylene at the Grangemouth factory of British Petroleum Chemicals, Ltd., is an outstanding manifestation of two of the major lines of the petroleum chemicals industry, which were well recognized by the symposium. The first is the tendency of the industry to offer an alternative route to chemicals previously made from vegetable products, and the second is the application of catalytic methods which dispense with the need for heavy inorganic chemicals that contribute no essential ingredient to the finished compound. The cost of producing alcohol by fermentation of molasses is dependent largely on the price of molasses, which is itself dependent upon world sugar production, cattle feed requirements (particularly in the United States) and the varying demand for industrial alcohol. So influential have these and other factors been that, during the past twenty years, the price of Cuban molasses has ranged from £3 10*s.* to £25 a ton. By basing the production of ethyl alcohol on petroleum-derived ethylene, it is confidently expected that a more stable price-structure, and one set at an economically lower level, will result. In the United States, half of the industrial alcohol produced is synthetic alcohol. The decision having been made to adopt petroleum as the base for alcohol manufacture, a choice had to be made between the two methods available, namely, by the well-established process of absorbing the ethylene in sulphuric acid to obtain the ethyl esters which are afterwards hydrolysed, or by the Shell method of hydrating ethylene directly, phosphoric acid on 'Celite' (a diatomaceous earth) being used as the catalyst. Mr. A. J. Johnson, presenting the paper prepared by Mr. C. R. Nelson and himself (Shell Development Co.), described this second and preferred course which eliminates the problems involved in the use of sulphuric acid, including those of reconcentration of the acid, disposal of impure acid, and corrosion effects. The direct hydration of ethylene is conducted at about 1,000 lb./sq. in. gauge and 300° C.; the molar ratio water/ethylene is 0·6, and the conversion of ethylene per pass is low (about 4 per cent). The choice of these reactor conditions is largely determined by economic considerations.

Two other instances of new processes, which avoid the use of substantial quantities of inorganic chemicals, were the subject of papers. The economics of the catalytic direct oxidation of ethylene by air over a silver catalyst to yield ethylene oxide, in contrast to the older chlorhydrin process which consumes large amounts of chlorine and lime (about two tons of each per ton of ethylene oxide made), were presented by Dr. E. T. Borrows and Mr. D. A. Caplin (Petrochemicals, Ltd.). On the basis of conservative estimates of capital costs and yields, the direct oxidation process shows significant advantages, particularly under competitive market conditions, which may be expected to force down the selling price of ethylene oxide. The meeting showed a lively interest in the technical aspects of the process, which the economic calculations tacitly assumed, and questions were put on the patent position, the catalysts used, the need for moderators to suppress 'hot spot' formation, the tolerable acetylene concentration in the feed gas, and the carbon monoxide in the recycle. Published data on these points are, however, scanty, and those members of the meeting who may have been in a position to contribute information on these matters withheld their views. The strong attitude of caution in accepting the claimed merits of the direct oxidation process might be dispelled if at least some of the data from existing plants in the United States were made available and if performance reports on the plants at present under construction in the United States and on the Continent of Europe, couched in something better than meaningless general terms, could, in due course, be released. Though it would be foolish to expect trade secrets to be given away, the paucity of performance data prevents impartial assessment, and retards, by some years, the more widespread adoption of a process that may well be as good as the paper economics imply.

Mr. F. E. Salt (The Distillers Co., Ltd.) provided the third example of an elegant process which dispenses with the use of heavy inorganic intermediates. The well-established methods for synthesizing phenol from benzene rely upon using sulphuric acid or chlorine as basic raw materials, and involve corrosive conditions. The new process developed by the Distillers Co. and the Hercules Powder Co. converts benzene and propylene, via *iso*propyl benzene, to phenol and acetone. Its advantages have been judged to warrant the construction of a number of plants overseas which are expected to come into production soon. The essential basis of the process—that is, alkylation, followed by oxidation to the hydroperoxide and its decomposition to the corresponding phenol and ketone—is of wide applicability; for example, *sec.*-butyl benzene yields phenol and ethyl methyl ketone; *m*- and *p*-di*iso*propyl benzenes yield acetone with resorcinol and quinol, respectively. The capital cost of a plant to produce 10,000 tons phenol a year and 6,000 tons acetone a year is estimated to be £1·75 million, which is slightly less than that required for phenol plants of the same capacity employing older processes. Further, if reasonable values (for example, 1952 price-levels) are taken for raw materials, utilities, labour and for the acetone credit, then the cost of production of phenol by this route is about 70–80 per cent of that by any of the other routes.

An outline of the production of polystyrene and its utilization in a variety of industries, as presented by Dr. V. G. Bashford and Mr. S. D. Eagleton (Monsanto Chemicals, Ltd.), raised questions relating to the use of methyl styrene. It appears that the use of methyl styrene offers the possibility of more rapid polymerization, and though the polymers are less suitable for injection moulding, they promise well for incorporation in surface coatings. The advantages of toughened polystyrene in comparison, say, with toughened polyvinyl chloride were discussed, and doubt was expressed as to the ability of the product to retain over periods of three to four years the high impact strength and improved elongation that the freshly prepared material possesses.

The paper by Mr. W. G. Oakes and Mr. H. C. Raine (Imperial Chemical Industries, Ltd.) on polythene was of outstanding merit in demonstrating the best features of the scientific approach in carrying a project through research and development to full-scale production, followed by the subsequent elaboration of the first direct course, so that a wider range of products of desired and predictable properties may be made. The fundamentals of polythene formation have been carefully examined, and many techniques and approaches have been used to elucidate the polymerization process and the structure and nature of the product. At first believed to be a straight-chain polymer, polythene is now known to be made up of molecular chains that are branched. The application of X-ray diffraction, infra-red spectrographic analysis, studies of osmotic pressure and viscosity of solutions, light scattering and other techniques have contributed to the present conception of the structure of polythene, but even now it is not fully resolved. Each finite sample of polythene is made up of molecules having quite a wide spread of molecular weight. The physical properties of the polymer depend upon both the chemical features and also on the arrangement of the molecules in relation to one another in the solid state. Polythene is partly crystalline: in the commercial material, probably about 70 per cent of the molecules are in the ordered state. The authors of this paper correlated chemical and structural features with electrical conductivity, melt viscosity, melt elasticity, softening point and mechanical and physical properties in the solid state. A point of interest which the discussion evoked was that, under the action of gamma-rays, cross-linking is caused, resulting in the transformation of polythene to a glassy, brittle solid. This effect is similar to that produced by a very prolonged photo-oxidation; the mechanism of the change is a matter for speculation.

A second paper from Imperial Chemical Industries, Ltd., on butane dehydrogenation, by Mr. E. Beesley and Dr. B. Whipp, was equally creditable as a record of the rapid development, in collaboration with Universal Oil Products, Ltd., of a process under the stress of war-time conditions of emergency and improvisation. A mixture of *iso* and *normal* butanes (usually 70 per cent *iso*) was dehydrogenated over an alkali-promoted chromia–alumina catalyst to the corresponding butenes. This essential step in the production of *iso*octane for aviation gasoline was brought to successful operation; one major difficulty, namely, the random choking of the reaction tubes due to excessive and unpredictable coke formation, was cured by introducing 30–40 p.p.m. carbon disulphide in the charge. The carbon disulphide was thought to passivate the tube material against alternate oxidation and reduction, thus preventing the catalysis of carbon formation by finely divided metal. In the discussion, it was said that the process is now in operation for the production of *iso*butene from *iso*butane in an integrated plant, wherein this step fits in with other industrial processes.

The separation and utilization of $C_4$ olefines, which are becoming increasingly available from the new oil refineries and petroleum chemicals cracking-plants, was reviewed by Dr. E. T. Borrows and Mr. W. L. Seddon (Petrochemicals, Ltd.). It is of particular interest that whereas the $C_4$ stream from oil-refinery catalytic crackers contains virtually no butadiene, the plants installed by petroleum chemicals works for the cracking of naphtha, gas oil, etc., yield a $C_4$ stream containing substantial amounts of butadiene. This constitutes both an opportunity and a problem. Considerable interest was shown in the authors' suggestion that, from a mixed $C_4$ stream containing butadiene, the *iso*butene may first be removed by selective absorption in sulphuric acid without absorbing appreciable amounts of the butadiene present; in fact, more than 90 per cent of the butadiene may be afterwards recovered.

The series of specialist papers was concluded by the paper by Dr. D. P. Dodgson (Monsanto Chemicals, Ltd.) on the use of additives based on petroleum for improving the quality of various petroleum fractions. A wide range of products, including chlorinated waxes, sulphonation products, naphthenic acids, viscosity index improvers, pourpoint depressants, etc., were dealt with. In the discussion, interest was shown in the use of additives to give oils of both high- and low-viscosity indices, and in the liability of viscosity index improvers to break down at high rates of shear. Dr. Dodgson gave the assurance that conventional lubricating oils containing additives from different manufacturers are, in general, mutually compatible.

Sir Robert Robinson, in the closing address, pointed out that the world chemical industry is highly competitive, and, if the British complement is to survive, it must keep in the race: any early financial losses in establishing the petroleum chemicals industry must be accepted; national and strategic interests make it imperative that the necessary capital to sustain development and growth of the industry must be found. The symposium, he said, rightly laid stress on an essential theme of this new industry: that is, its facility for developing alternative processes which do not require the use of substantial quantities of heavy inorganic chemicals, for example, in the production of acetone and phenol by the Distillers Co., Ltd., process, and of ethylene oxide by the catalytic oxidation of ethylene. This theme should be vigorously developed. Research over a broad front on catalysis should be conducted, and in this attack, continued Sir Robert, government departments such as the Chemical Research Laboratory and the Fuel Research Station of the Department of Scientific and Industrial Research should play an outstanding part. Recent research has demonstrated that there are many reactions and processes which hold high promise of industrial exploitation in Britain: the Fischer–Tropsch reaction and the Oxo syntheses are well-known examples. The recent work of Ziegler on the use of lithium and aluminium hydrides as catalysts in controlled polymerization processes may also lead to economic routes to both known and new products. These are only examples of the many opportunities, some known, some awaiting discovery, that lie before us, and only by our own energy and unsparing effort can they be won.

---

# CLAY – WATER RELATIONSHIPS

A MEETING of the Clay Minerals Group of the Mineralogical Society, held at the laboratories of the British Ceramic Research Association, Stoke-on-Trent, during November 7–8 last, was devoted to a discussion upon clay – water relationships. The meeting was preceded, on the morning of November 7, by a visit to the laboratories of the Association. At the scientific sessions the chair was taken on the afternoon of November 7 by Dr. G. W. Brindley (University of Leeds), and on the morning of the following day by Dr. G. Nagelschmidt (Safety in Mines Establishment, Sheffield).

The discussion was opened by a review of the significance of clay – water relationships in ceramics by D. A. Holdridge and F. Moore (British Ceramic Research Association). Plasticity and strength data as well as the Pfefferkorn and modified Pfefferkorn numbers for ball and china clays were related to dehydration data, and discussed in relation to the concept of 'planar' and 'broken-bond' water; the former is removed below 110° C., but removal of the latter is incomplete below about 250–275° C. In describing the rheological properties of importance for clay slips and pastes, particular attention was paid to the methods for determination of viscosity and plasticity and their applicability. The rheology of thixotropic gels was also discussed. In the discussion, the different dehydration characteristics of china clay and ball clay were commented upon by R. Greene-Kelly (Rothamsted Experimental Station, Harpenden) and by Dr. Brindley, who also referred to recent dehydration data for nacrite[1]. G. K. Jones (Fuller's Earth Union, Redhill), Dr. N. O. Clark (English Clays, St. Austell) and Mr. Moore discussed the relationship of dilatancy, turbulence and shearing, and R. H. S. Robertson (Glasgow) inquired about the relationship of the modulus of rupture to the moisture content.

Soluble salts may have deleterious effects upon clay products—for example, efflorescence in bricks—and the determination of these in clayey raw materials was discussed by Prof. H. Lehmann (Bergakademie, Clausthal-Zellerfeld), who showed that extraction by a percolation method after firing gives the most useful information. Using this technique, it has been found that efflorescence is not related to the amount of soluble salts alone, but that it is also dependent upon pore space, pore characteristics, firing temperature and the density and chemical characteristics of the specimen. Correlation of efflorescence with firing temperature, the effect of various ions and the possibility of control of conditions leading to efflorescence were discussed. In reply to comments by B. Butterworth (Building Research Station, Watford), Prof. Lehmann stressed that he had considered only clays in which his laboratory is interested, and agreed that higher sulphate contents are not uncommon; he also mentioned that, in Germany, determination of soluble salts in the raw material is still used to assess a clay. Other speakers referred to the effect of association of bricks with cement products and the question of the total soluble salts. In reply to W. Noble (British Ceramic Research Association), Prof. Lehmann remarked that the effect of the *p*H of the extracting solution has not yet been considered.

The deflocculation of kaolinite suspensions and its relationship to chloride adsorption has been investigated by Dr. R. K. Schofield and H. R. Samson (Rothamsted Experimental Station), who found that a flocculated sodium–kaolinite suspension in contact with less than a critical amount of sodium hydroxide takes up chlorine ions from dilute sodium chloride solution; when deflocculation occurs, full negative adsorption is observed. These results are related to questions of cation-exchange by kaolinite, since, from the observations made, exposed hydroxyl groups at the surface would only be expected to give exchangeable hydrogen ions under alkaline conditions. In addition, montmorillonoids might, under certain conditions, be sorbed by kaolinite to neutralize positive charges. Mr. Greene-Kelly and Dr. Clark both commented upon the significance of the above results in work involving dispersion of mixtures of clay minerals, where one mineral may be preferentially deflocculated. Dr. D. M. C. MacEwan (Rothamsted Experimental Station) pointed out that the remarks upon dissociation of hydroxyl groups were in disagreement with the views of Edelman and Favejee[2], and that the results might be significant in determining the true structure of montmorillonite[3].

To investigate the relationship between viscosity and concentration for three clays of the kaolin group, T. E. Currie and Dr. R. W. Grimshaw (University of Leeds) employed electron-optically checked samples of uniform particle-size. The viscosity/concentration curves were all similar in shape and could be derived from equations employing a series of constants dependent upon degree of dispersion, upon particle-size, and upon type of clay mineral present. In general, the viscosity was more dependent upon particle-size than upon type of mineral. Dr. Grimshaw, replying to Dr. Nagelschmidt, reported that constant shearing stress had been used, although the same general conclusions were applicable under different conditions. Dr. Clark questioned whether the relatively constant thickness-ratio for kaolinite grains in the various fractions could be taken as a universal rule, and in this connexion Mr. Robertson referred to some work upon the relationships of viscosity to rugosity[4] and to particle size for various kaolin clays[5]. The rigidity of the water envelope around clay particles and its effect upon results were also discussed by Dr. Clark and Dr. Grimshaw.

In a review of the subject of thixotropy and the internal swelling of crystals, Prof. U. Hofmann (Technische Hochschule, Darmstadt) described a very neat method, employing freeze-drying technique, of obtaining dry undisturbed clay-gel structures for examination under the electron microscope. These structures alter very little in volume during drying, and it is considered that the relative positions of particles are virtually unchanged; the framework is reasonably solid, very stable and even has a certain elasticity—properties which were demonstrated by a sample passed among members of the meeting. The effect of electrolytes upon the volume of coagulated clay gels, and the forces operative here and in maintaining the solidity of the framework were discussed. Prof. Hofmann also reported the results of an investigation upon thixotropy in non-aqueous liquids, for example, hexane and benzene. In the discussion, Dr. Nagelschmidt referred to the occurrence of thixotropy in systems with spherical particles, and Mr. Samson, Dr. Clark and Prof. Hofmann discussed general questions upon thixotropy and the arrangement of particles in flocculated systems. The formation of dipoles, and the dielectric constants of suspensions were referred to by Dr. Clark and Mr. Jones, and finally Prof. Hofmann, in addition to Dr. Clark and Dr. P. Howard (University of Leeds), suggested other methods whereby dry, undisturbed clay structures might be produced.

The conditions under which montmorillonoids lose their expanding properties on heating were described by R. Greene-Kelly, who related the changes occurring with crystal structure[6]. For example, if lithium-saturated montmorillonoids are heated to 200° C. and treated with glycerol, only dioctahedral components with the charge in the tetrahedral layer (that is, the beidellite type) will swell. Reference was made to the sorption of water by sodium-montmorillonoids, and some notes were given upon the information to be derived from such measurements. Mr. Greene-Kelly, in reply to Dr. R. C. Mackenzie (Macaulay Institute, Aberdeen), reported that he had not examined beryllium-montmorillonoids because of the hazards of the acidity of stable solutions of $Be^{2+}$ salts. Further discussion took place upon the effect of lithium ions upon the cation-exchange capacity of montmorillonoids and the possibility of such ions entering the lattice, these points being raised by Dr. Nagelschmidt and Dr. B. S. Neumann (Fuller's Earth Union).

Dr. G. W. Brindley and R. F. Youell (University of Leeds) showed that, during the oxidation of ferrous to ferric chamosite, there occurs a partial dehydration which can be related to the lattice positions of the hydroxyl groups. The retention of water and structural order to high temperatures during the dehydration of nacrite[1] was also demonstrated. These results were considered in relation to oxidation–dehydration processes in other minerals, and, as an example, it was shown that chemical analyses for decomposition products of biotite[7] can only give reasonable structural formulæ using assumptions derived from the above experiments. The derivation of good structural formulæ was commented upon by Dr. MacEwan, Dr. Nagelschmidt and Dr. Mackenzie, while Dr. S. J. Gregg (University College, Exeter) compared the retention of water by silicates to a high temperature with the retention of water and carbon dioxide by other compounds. Dr. H. P. Rooksby (General Electric Co., Wembley) referred to the retention of water by $\gamma$-$Al_2O_3$, and, in reply to his questions on the structural dehydration data, Dr. Brindley stressed the slowness of heating and the reproducibility of results even with broken crystals. The mechanism of the dehydration of kaolinite, with special reference to the work of White *et al.*[8], was also discussed by Dr. Nagelschmidt, Dr. Grimshaw, Dr. Howard, Mr. Youell and Dr. Brindley.

The final paper was not upon the subject for discussion although it had an indirect connexion. In order to determine the effect of grinding on kaolinite, Dr. S. J. Gregg, T. W. Parker (English Clays, St. Austell) and Mrs. M. J. Stevens (University College, Exeter) ball-milled a sample for a thousand hours, withdrawing aliquots at intervals for various physical and chemical tests—for example, X-ray examination, air sedimentation, loss on ignition, etc. Up to six hundred hours, the primary particles were decomposed chemically as well as broken physically, and the products formed an amorphous layer on the somewhat disorganized, undecomposed particles. The resultant particles, which possess an internal area, resisted complete dispersion and, after six hundred hours, the proportion of stable aggregates increased. During discussion, questions were asked by Mr. Greene-Kelly, Mr. Henderson, Mr. Jones, Dr. Neumann, Dr. MacEwan, I. L. Freeman (London Brick Co., Stewartby) and Dr. Mackenzie upon the method of sampling, the wear on the ball-mill, the uniformity of particle size, density measurements and the stability of aggregates. The possibility of interference of electrostatic charges with air-sedimentation tests was suggested by Dr. P. L. Plesch (University College, Stoke-on-Trent), and, in reply to a question by Mr. R. Johnson (British Ceramic Research Association), Dr. Gregg pointed out the significance of the inter-relationship of measurements of bulk density, sedimentation and surface area. The X-ray results were discussed by Dr. Brindley and E. K. Cundy (English Clays) and the amorphous coating, or 'Beilby layer', by Mr. Robertson.

Before the end of the meeting, two brief reports—one on the conference on clays and clay technology, held at the University of California during July 21–52, 1952, and one on the meetings of the Comité International pour l'Étude des Argiles, held in conjunction with the Nineteenth International Geological Congress, Algiers, during September 8–15, 1952—were presented by Dr. MacEwan and Dr. Mackenzie, respectively.

This meeting, as a whole, proved most valuable, giving ample proof of the significance of clay – water relationships in all aspects of clay studies, both pure and applied. Its value was enhanced by the concentration on problems which our present knowledge is insufficient to solve, but which might well form the subject of future research.

# RADIO RESEARCH IN THE BRITISH COMMONWEALTH

AT the meeting of the British Commonwealth Scientific Official Conference in 1946, a Specialist Conference on Radio Research was convened and was held in London during August 1948 under the chairmanship of Dr. R. L. Smith-Rose. The proceedings of this Conference, which were published (S.O. Code No. 47-148-1949; London: H.M.S.O.; 4*d.* net), included a number of recommendations designed to encourage the Commonwealth countries to participate more actively in a comprehensive programme of fundamental radio research. This programme included such items as proposals for the location of ionospheric recorder equipment for determining the characteristics of the ionosphere at vertical incidence, the study of the propagation of radio waves at oblique incidence and the comparison of radio transmission forecasts with the results of the practical operation of radio circuits. Other matters were concerned with radio noise of both terrestrial and extra-terrestrial origin, the investigation of meteors by radio methods, and with a study of the effect of meteorological conditions on the propagation of very short radio waves. Suggestions were also made for extending the limited services of standard frequency transmission, and for collecting information to increase our knowledge of the electrical constants of the ground in all parts of the Commonwealth.

The progress made towards the implementation of these recommendations has been reviewed on two occasions by correspondence through the British Commonwealth Scientific Liaison Offices in London; and last August in Sydney, Dr. Smith-Rose held another meeting of the Specialist Conference, taking advantage of the presence there of a number of radio scientists attending the General Assembly of the International Scientific Radio Union. It was noted that considerable progress has been made in extending the network of ionospheric recording stations throughout the Commonwealth. In addition to the stations in Great Britain at Slough and Inverness, the United Kingdom has maintained similar stations at Singapore and in the Falkland Islands; and more recently an experimental equipment has also been in operation at Port Lockroy in Antarctica. Furthermore, similar recorder equipment has been installed by the United Kingdom Department of Scientific and Industrial Research at Ibadan, Nigeria, and at Khartoum, where it is now being operated by the University

College authorities at those places. The Canadian authorities have installed new stations at Fort Chimo, Resolute Bay and Baker Lake; and South Africa has assisted the Belgian Congo authorities to build a station at Leopoldville. The Australian Radio Research Board responded very actively to the recommendation that a chain of ionospheric observatories should be operated in the vicinity of longitude 150° E. by setting up recorders at Hobart, Canberra, Brisbane and Townsville. Furthermore, a station has been set up at Macquarie Island which should be of great assistance in the study of ionospheric conditions in antarctic regions. In India, ionospheric recorders of various types have been installed at Delhi, Calcutta, Ahmadabad and Kodaikanal.

Research on the absorption of radio waves travelling through the ionosphere is being actively pursued in the United Kingdom and in Australia, Canada and India; and the results are used, with other ionospheric information, in a comparison of radio transmission forecasts with practical results. Investigations are also in progress in most Commonwealth countries with the view of improving the forecasting of ionospheric storms, which on occasions cause serious interruption of practical radio services, including communication and broadcasting.

For several years past, measurements of the atmospheric radio noise-level prevailing at frequencies of 2–20 Mc./s. have been made by a subjective method at some twelve stations in various countries; and development work is in hand to extend this investigation to frequencies of 15–500 kc./s. in order to provide more direct information on the performance of low-frequency radio aids to navigation. Fundamental investigations on atmospheric disturbances, including in some cases a detailed study of waveforms, are in progress in the United Kingdom, India and South Africa. A recommendation was made at the Sydney meeting that the high-frequency noise-measuring equipments in Australia and New Zealand should be put into operation again as soon as possible, since continuity of the study of atmospheric noise for several years all over the world is essential for the ultimate improvement of the efficiency of operation of all radio services.

Following a recommendation made at the London meeting in 1948, the New Zealand authorities have been able to initiate in the southern hemisphere the study of meteors by radio methods, as a field of research complementary to that pursued in the United Kingdom. The collaboration between the two countries has been very effective, and it is now recommended that the work in New Zealand should be continued and extended so far as practicable.

The extremely short-wave portion of the radio spectrum is likely to be of very great importance to the future of radio services of all types. With this in mind, a strong recommendation was made at the Sydney meeting that research on tropospheric wave propagation should be vigorously pursued in all countries in order to improve our knowledge of the influence of different climatic conditions on the possible correlation between radio propagation and meteorological conditions. A considerable amount of investigation work in this field has been conducted during recent years in New Zealand, and in the United Kingdom; but there is a need for a continued study of the effects experienced under different conditions and at various frequencies in order to assist those responsible for planning future radio systems and services.

The extensive research work on solar and cosmic noise, which is now embraced under the general title of 'radio astronomy' and which has been pursued in several countries, notably in Australia and the United Kingdom, is too well known to need any detailed reference here. It may be remarked, however, that the meeting in Australia of the International Scientific Radio Union provided an excellent opportunity for some of the workers in this field to meet and discuss matters of mutual interest, and particularly to compare the results of experience in the northern and southern hemispheres.

In February 1950 the United Kingdom established a limited regular service of standard-frequency transmissions from the Rugby radio station of the General Post Office, using the call-sign *MSF*. The service provides transmissions for short periods daily on frequencies of 60 kc./s. and on 5 and 10 Mc./s. These transmitted frequencies are monitored by the National Physical Laboratory, and the latter's observations show that over a period of a day the frequency remains constant to about 1 part in $10^8$, a slow drift of frequency over longer periods being corrected whenever the deviation from the nominal value approaches 2 parts in $10^8$. Apart from this service, the Union Observatory in South Africa radiates time signals, and a standard frequency transmission is made on low power from Johannesburg. The Australian authorities are also exploring the possibilities of establishing a standard-frequency service to meet local requirements in that continent.

With regard to the measurement of the electrical characteristics of the ground at radio frequencies, in Canada, South Africa and South-West Africa, surveys of conductivity by radio methods have been in progress for some years; and the All-India Radio organization is starting systematic measurements of the electrical properties of the ground throughout India. It is realized that this type of investigation should be pursued in close association with a study of the effects of the contours of the terrain on ground-wave propagation at various frequencies. It is considered, however, that the original recommendation should be retained with the view of encouraging Commonwealth radio organizations to collect all appropriate information on measurements made in their own countries, to facilitate the preparation by the United Kingdom of a survey of existing knowledge of the electrical constants of the ground at radio frequencies.

# HUMAN FACTORS IN INDUSTRY

TWO committees to work on human problems in industry have been set up jointly by the Department of Scientific and Industrial Research and the Medical Research Council, one being concerned with human factors in individual efficiency, and the other with human relations. The division of interest between the committees is broadly that the first will study the individual worker and his job, and the second such things as the relation between the manager and the worker, between the worker and his mates and between the foreman and the technical specialist.

The subjects to be considered can be listed under four headings, the first three of which are, in general, the responsibility of the committee on industrial efficiency, and the fourth is that of the committee on human relations: fitting the job to the man—work on the design of tools and working equipment to suit the man who uses them (which is getting more important as machines become more complicated), time and motion study, and the effect of factory lighting, heating and noise, etc., on performance; selection and training; assessing the job—work measurement, job appraisal, time and motion study as a means of assessing a fair day's work, etc.; human behaviour and human relations—joint consultation, attitudes to work and the structure of informal groups in the factory. For research on matters relating to occupational health, the Medical Research Council will continue to be responsible, advised by its own special committees. However, in order to secure co-operation on technical aspects, the Department of Scientific and Industrial Research will be asked to appoint assessors to these committees where appropriate; for example, the elimination of dust from factories, although primarily a medical problem, may bring in the Department or the research associations to develop means of combating dust.

The scientific study of the human factors in industry is not, of course, a new venture: notable contributions have come in the past from the researches of the Medical Research Council's Industrial Health Research Board on, for example, how hours of work affect output and health, the influence of environmental factors such as lighting and heating, and the effects of incentives; and the Panel on Human Factors of the post-war Committee on Industrial Productivity has also done important work, including an investigation of the foreman in British industry. However, the need for much more of this kind of research is realized, and the aim of the two new committees will be to develop knowledge which can be used to make definite recommendations, the underlying object being to improve industrial production in Great Britain. For this reason, the committees include persons from industry, trades unions and universities.

*Committee on Individual Efficiency in Industry.* The terms of reference of this committee are: "(1) To keep under review the progress of knowledge bearing on the technical efficiency of the individual in industry. (2) To advise on general policy in research, including applied research and field study. (3) To call attention to gaps, and make recommendations for filling them. (4) To consider and report from time to time on the requirements for the training of research workers and technologists in this field". Its members are as follows: Sir Frederic Bartlett (*chairman*) (formerly professor of experimental psychology, University of Cambridge), W. V. Beard (general secretary, United Patternmakers' Association), J. O. Blair-Cunynghame (chief personnel officer, British Overseas Airways Corporation), Prof. J. V. Connolly (Department of Aircraft Economics and Production, College of Aeronautics, Cranfield, Beds), J. Crawford (general president, National Union of Boot and Shoe Operatives; member of the Advisory Council, Department of Scientific and Industrial Research), Prof. J. Drever (Department of Psychology, University of Edinburgh), Dr. C. B. Frisby (director, National Institute of Industrial Psychology, London), L. V. Green (head of the Personnel Research Department, Dunlop Rubber Co., Ltd.), Prof. Esther M. Killick (Department of Physiology, Royal Free Hospital School of Medicine, London), Prof. W. E. Le Gros Clark (Department of Human Anatomy, University of Oxford), N. G. McCulloch (deputy chairman, Calico Printers' Association, Ltd.; chairman, Council of the British Cotton Industry Research Association), Prof. R. W. Russell (Department of Psychology, University College, London), Miss Nora Wynne (director, Carr's Biscuits, Ltd.), and an assessor from the Ministry of Labour and National Service. The joint secretaries are Dr. B. S. Lush (for the Medical Research Council) and Winston Rodgers (for the Department of Scientific and Industrial Research).

*Committee on Human Relations in Industry.* The terms of reference of the committee are: "To examine current activities concerning the study of human relations in industry and to call attention to problems of special timeliness or promise on which research, including applied research and field study, might be undertaken or supported by the Department of Scientific and Industrial Research, the Medical Research Council, or other bodies". Its members are as follows: A. B. Waring (*chairman*) (chairman and managing director, Joseph Lucas Industries, Ltd.), J. Foster Beaver (chairman, Beaver and Company (Bingley), Ltd.), J. O. Blair-Cunynghame (chief personnel officer, British Overseas Airways Corporation), A. D. Bonham-Carter (head of the Personnel Division, Unilever, Ltd.), Prof. T. Ferguson (Department of Public Health, University of Glasgow), E. Fletcher (member of the Advisory Council, Department of Scientific and Industrial Research; head of the Productivity Department, Trades Union Congress), Miss Beryl Foyle (joint managing director, Boxfoldia, Ltd.), Prof. A. J. Lewis (Institute of Psychiatry, University of London; and member of Medical Research Council), Prof. R. W. Russell (Department of Psychology, University College, London), Miss B. N. Seear (Department of Social Science, London School of Economics), Prof. T. S. Simey (Department of Social Science, University of Liverpool), W. R. Verdon Smith (managing director, Bristol Aeroplane Co., Ltd.), T. Williamson (General Council, Trades Union Congress), Dr. A. T. M. Wilson (director, Tavistock Institute of Human Relations), and an assessor from the Ministry of Labour and National Service. The joint secretaries are J. R. Gass (for the Department of Scientific and Industrial Research) and Dr. B. S. Lush (for the Medical Research Council).

# TEACHING OF NATURAL SCIENCE IN SECONDARY SCHOOLS

In view of the pressing needs for a more thorough and efficient teaching of science, a comparison and free flow of ideas between teachers, of all nations, of this subject would be useful. A number of accounts of different aspects of comparative education have been published by the United Nations Educational, Scientific and Cultural Organization, and a recent volume, "The Teaching of Natural Science in Secondary Schools"*, is compiled from information supplied to the International Bureau of Education, Geneva, by the ministries of education of all countries, apart from the U.S.S.R. and its satellite States. This is a valuable piece of work, and such efforts are to be encouraged; but it suffers from undue compression, as well as vagueness and scrappiness of treatment at times. Sometimes it gives a statement of intentions and ideals rather than of achievements; some of the accounts of science-teaching are clearly derived from those of other nations, and at times we do not get a clear idea of what is meant by secondary education. The vagueness of the official statement which does not want to commit itself to well-defined terms seems to be common to many countries. An example of this (which could be multiplied many times throughout the book) taken from the United Kingdom (England and Wales) Section will show the difficulties of the compiler: "Natural Science teaching is sometimes optional. It is left to the discretion of the individual school. The same importance is given to Natural Science in comparison with other subjects in promotion examinations and the Secondary School leaving examination".

---

* Unesco: International Bureau of Education. Publication No. 139: XVth International Conference on Public Education, convened by Unesco and the I.B.E., Geneva, 1952. Teaching of Natural Science in Secondary Schools. Pp. 216. (Paris: Unesco. Geneva: I.B.E. London: H.M.S.O., 1952.) 5 Swiss francs or 8s. 6d.

The book is a sequel to an "Introduction to Natural Science in Primary Schools", prepared by the International Bureau of Education for the Twelfth International Conference on Public Education, held in 1949. The teaching of physics and chemistry is reserved for a later inquiry, and so the present work is confined to biology and its branches, physiology and anatomy, geology and mineralogy. To take away physics and chemistry from a report on science teaching would seem to be unfortunate. A definition of natural science which purposely excludes the fundamental studies of the physical sciences is unwise, and in any event they are not excluded in the reports which are sent in by some of the ministries. The information was given under a number of headings: the place of natural science in the curriculum, the aims of natural science teaching, syllabuses, teaching methods (including visual aids and text-books), teaching staff and future intentions. It is impossible to summarize further the results of the inquiry as they are set forth in the general survey in the early part of the book; but much of the information sent from forty-eight countries would have been grasped more readily had it been set out in tabulated form. It is evident that the countries concerned are unanimous in wishing to make natural science teaching more experimental and to bring it into closer touch with life, and that there is an increasing emphasis on the biological aspects of the subject. Science teaching in nearly all countries is related to human needs—individual, national and social. Some countries, including Germany, stress the ethical and philosophical aspects of science, its disciplines and opportunities for patience and criticism; the United Kingdom mentions its interest and hobby values; other countries indicate its relation to geography and its value as a means to a better understanding and use of the natural resources of the country.

The account of science teaching in England and Wales is disappointing, and does not do justice to work which is being carried on. To a foreign reader it must seem unimpressive. A clear statement should have been given of the division of secondary education in Britain, since the 1944 Act, into 'grammar', 'technical' and 'modern'. The report is chiefly concerned with modern schools (the old 'central schools'); grammar schools are only mentioned in passing, and secondary technical schools not at all. Although it is important that all citizens should leave school with some knowledge of biology, particularly in regard to the nature and needs of mankind, the fact remains that in Britain it is the grammar and public schools to which we must look for the type of science teaching which in the end produces scientists and technologists. The national and international value of the science teaching in these schools from 1902 until 1944 cannot be over-estimated. The need of the future for the type of scientific worker who comes from these schools is greater than ever before; indeed, there will be no future for Britain unless its life is sustained by an increasing number of workers thoroughly trained in the skills and disciplines of science. With the best will in the world, the modern schools do not meet these needs, in spite of the fact that they cater for the majority of children. Some of them do not teach science, many of them have no adequate course for the important age-group of 14–15 years, and, in spite of the optimistic Ministry of Education booklets mentioned in the report under review, some of these schools have not yet given adequate thought to their schemes of work. So far as the scientific life of the nation was concerned, the grammar and public schools laid the golden eggs; but they have been inhibited in their work by factors which could have been foreseen in 1945. No science graduate with a good honours degree needs to consider teaching as a career unless he has strong vocational leanings. Recruitment for the science staffs of grammar schools is suffering in both the quantity and quality of applicants to fill the vacancies. This has its repercussions on the attainments of students reaching the universities and on their subsequent value to society. Nor is this improved by feeble official attempts to assure us that the position is not unsatisfactory.

The document makes no attempt at appraisal of the various aims and methods, nor does it stress particularly good or original points where they appear. It will be of more interest to the student of comparative education than to the practical science teacher, who will find that it does not touch the fringe of most of the matters so admirably dealt with in the report on the "Teaching of General Science", prepared by the Science Masters' Association in 1950.

W. L. SUMNER

# SOCIAL ANTHROPOLOGICAL STUDIES OF LATIN AMERICA

THROUGHOUT Latin America there is a desire to improve conditions and to overcome difficulties which hinder national development, the greatest being the low estate of the Indian. In order to do this the first necessity is adequate information about things as they are, and the Institute of Social Anthropology of the Smithsonian Institution is helping to provide it by publishing a series of descriptive studies, of which Nos. 10–14 have been published during the past two years or more*. The policy of the Institute is to co-operate wherever possible with the various national organizations, and the present series owes much to students of the Mexican Escuela

* Smithsonian Institution: Institute of Social Anthropology. Publication No. 10: Nomads of the Long Bow; the Siriono of Eastern Bolivia. By Allan R. Holmberg. Pp. iv+104+7 plates. 65 cents. Publication No. 11: Quiroga, a Mexican Municipio. By Donald D. Brand, assisted by José Corona Núñez. Pp. v+242+35 plates. 1·75 dollars. Publication No. 12: Cruz das Almas, a Brazilian Village. By Donald Pierson and others. Pp. x+226+20 plates. Publication No. 13: The Tajin Totonac, Part 1, History, Subsistence, Shelter and Technology. By Isabel Kelly and Angel Palerm. Pp. xiv+369+33 plates. 2·75 dollars. Publication No. 14: The Indian Caste of Peru, 1795–1940: a Population Study based upon Tax Records and Census Reports. By George Kubler. Pp. vi+71+2 plates. 75 cents. (Washington, D.C.: Government Printing Office, 1950–1952.)

Nacional de Antropología e Historia, the Brazilian Escola Livre de Sociologia e Política of São Paulo, and the Peruvian Instituto de Estudios Etnológicos.

The author of No. 10 spent about eighteen months studying the unacculturated remnants of the Siriono, a very primitive naked tribe living in the tropical forests of Eastern Bolivia. For a third of this time he and a Bolivian companion lived alone with a small group. Conditions were very difficult, and his time was cut short by the entry of the United States into the Second World War in 1942, so he is not satisfied that he really understood the Siriono; but he collected a lot of information about their material culture, activities, beliefs and social organization, which is set forth in a good straightforward description. In the final chapter, he analyses their culture in terms of "drives", of which the chief is hunger.

No. 11, dealing with a municipality of mixed white, mestizo and Tarascan Indian population near Lake Pátzcuaro in Michoacan, Mexico, is by a human geographer. It is a detailed and interesting description of selected aspects of life in Quiroga, with emphasis on land settlement, government and economy, little attention being paid to sociology because a colleague was studying it in a neighbouring town (No. 6 of the series). The area is well known to ethnologists from the survival of primitive methods of hunting birds on the lake, and is at present the scene of a Unesco welfare project.

A detailed account is given in No. 12 of a village near São Paulo, to which the imaginary name of Cruz das Almas was given to preserve anonymity. It was picked out as a typical Brazilian rural community of mixed European, Indian and African descent, depending mainly on agriculture. It proved to be homogeneous and stable, with no very striking features and practically no vestiges of aboriginal Indian culture.

By contrast, No. 13 deals with the district around Tajin, a Mexican area of great historical and archæological interest, with a rich material culture about which it is a mine of useful information. The population is Totonac, and their culture is a living one compounded from old and new elements. The historical background is particularly necessary to its understanding, and a good deal of the report is devoted to this, Isabel Kelly, as an archæologist, being well qualified to deal with it. This first part, covering history, subsistence, shelter and technology, makes a substantial volume; and clothing, with several other aspects of material culture, together with what is described as non-material culture, will form Part 2.

No. 14, "The Indian Caste of Peru, 1795–1940", is a product of Dr. George Kubler's researches among the official archives of Peru while working in Lima during 1948–49. Although the word 'caste' is used in the title in association with the Indians, the Spanish word *casta* was generally used in Peru to refer to mestizos, albeit rather loosely as the author explains in detail. The work is a study of the variations in the percentage of Indians in the total population since just before the Independence. It seems that the Indian proportion rose during the first few years of the period studied, thus reversing a trend that had existed since the Spanish conquest, but that the fall afterwards continued, so that Indians now form about 40 per cent of the population. The problem is much complicated by the difficulty of defining an Indian, since the definition depends not wholly on biological factors but very considerably on social ones also.

# ACCELERATING EFFECT OF AN EXTRACT OF VERNALIZED EMBRYOS OF WINTER RYE ON FLOWER INITIATION IN UNVERNALIZED EMBRYOS

By O. N. PURVIS and PROF. F. G. GREGORY, F.R.S.

Research Institute of Plant Physiology, Imperial College of Science and Technology, London, S.W.7

THE theory that flowering requires the presence of some specific flower-forming substance is rejected by some writers on the grounds that the application to uninduced plants of extracts of induced plants has not led to flowering or at best given inconclusive results. This argument is not, however, valid, since the active materials, which are known to move about in the plant and to pass a graft union, may well be inactive in a plant extract. Possible causes of failure are manifold: the solvent may fail to extract the substance, or may inactivate it; it may not be absorbed by the test plant in sufficient quantity to produce a determinable effect, or it may only be active in association with the living protoplasm.

Small effects of plant extracts have been reported from time to time. Bonner and Bonner[1] induced flowering in *Xanthium* by applying an aqueous extract of the stem apex of *Washingtonia robusta*. Loehwing[2] and Behrens[3] report activity of extracts of *Zea mays* and *Sempervivum*, respectively. Sironval[4] obtained an oil from leaves of induced strawberry plants which, applied to leaves of young plants, led to normal flowering in a proportion of the plants treated, while the control plants produced rather fewer inflorescences and no fully developed flowers. Roberts[5] found that extracts of various plants in a flowering condition had a slight inductive effect on *Xanthium*. On the other hand, Melchers and Lang[6] report that careful experiment has failed to extract any florigenic substance.

In these examples the extracted plants were brought into the flowering condition by photoperiodic treatment. It therefore seemed necessary to determine if extracts of vernalized grain could confer the vernalized condition on plants which had not received this treatment. In 1951, embryos were removed from rye grain which had been vernalized for ten weeks, and were extracted with water, chloroform, ethyl alcohol or ether. The extracts, after removal of the solvents, were added to a sucrose agar medium[7]. Unvernalized embryos were excised and grown for six days on this medium, at a concentration which presented to each test embryo the extract of ten vernalized embryos. A control series was germinated on medium without extract. The seedlings were planted out in sand culture.

The results of this experiment are given in Table 1. Unfortunately a single plant in the control series flowered in 118 days: such early flowering had not been encountered in unvernalized plants grown from excised embryos, though it is fairly frequent when intact unvernalized grain is used. In the table it will be seen that despite the inclusion of this obviously aberrant plant the 'score', that is, progress to flowering[8], of the control series is more than six points below that of the series treated with chloroform

Table 1. EFFECT OF EXTRACTS OF VERNALIZED EMBRYOS ON PLANTS GROWN FROM UNVERNALIZED EMBRYO 'SCORES'

| No extract | | Extracts of vernalized embryos in various solvents | | | |
|---|---|---|---|---|---|
| Whole grain | Excised embryos | Water | Chloroform | Ether | Alcohol |
| (20)<br>27±2·0 | (14)<br>22±3·6 (*a*) | (13)<br>24±3·1 | (13)<br>29±2·2 | (10)<br>19±1·4 | (9)<br>20±2·4 |
| | (13)<br>19±1·6 (*b*) | | | | |

Differences: No extract (*a*) and chloroform, 6·4 ± 4·3; no extract (*b*) and chloroform, 9·6 ± 2·8; no extract (*b*) and water, 5·4 ± 3·5. Control including one aberrant plant (*a*); control excluding this plant (*b*). Number of replicates in brackets

extract, which equals that of the intact grain series. This difference is not significant, but by omitting the aberrant plant (second row in Table 1) a highly significant difference is shown. The use of extracts in water, ethyl alcohol and ether produced negligible differences in flowering behaviour.

This result was inconclusive, but indicated the need for further investigation; the experiment was therefore repeated in 1952, using only chloroform as solvent. To ensure contact between the roots of the test embryos and the extract, the fatty material was deposited on fine angular sand while the chloroform was being removed by evaporation under reduced pressure. A fixed volume of the sand holding the amount of extract required was moistened with sterile water and added to the surface of the agar slopes on which the test embryos were grown. Care was taken to avoid fungal contamination, which occurred in less than 1 per cent of the cultures. After six days at 15° C. the embryos were planted out in sand culture. The 'scores' are given in Table 2: the concentration of the extracts is given in terms of the number of vernalized embryos in the extract presented to each test embryo. As additional control a series with extract of unvernalized embryos was added.

Table 2

| | Extract from varying numbers of vernalized embryos | | | | Extract from unvernalized embryos |
|---|---|---|---|---|---|
| | 10 | 4 | 2 | 0 | 10 |
| Excised embryos | (18)<br>29±1·8 | (15)<br>21±1·9 | (21)<br>24±1·7 | (21)<br>24±1·7 | (14)<br>22±2·0 |
| Whole grain | (24)<br>28±1·5 | | | (23)<br>20±1·5 | |

Differences: Extracts from vernalized and unvernalized embryos, 6·9 ± 2·7; extracts from vernalized embryos and no extract, 5·3 ± 2·4; extracts from 10 and 2 embryos, 5·6 ± 2·4. Number of replicates in brackets

Here the effect of using *vernalised* embryos for the extract is highly significant, and the possible effect of the chloroform or of the other normal constituent of the embryos is eliminated. Lower concentrations were without effect. The acceleration of flowering is small and not commensurate with the amount of vernalized material put into each culture. The effect on the unvernalized embryos is, however, equivalent to that of nearly three weeks of vernalization. This may be due to the limitations of the extraction technique enumerated above, or it may be that the active substance is not identical with that produced by the complete vernalization reaction. It would be premature to speculate on this result in terms of the substances postulated in our hypothetical scheme for the vernalization reaction[8].

# CHEMICAL DOSIMETRY AT HIGH DOSE-RATES

By Dr. N. MILLER

Department of Natural Philosophy, University of Edinburgh

CHEMICAL methods for the measurement of dosage of ionizing radiation have lately assumed increasing importance, and are now in wide use, particularly in studies of the radiation chemistry of aqueous media[1]. There has, however, been some doubt as to whether the methods so far proposed can be used successfully at high dose-rates of X- or γ-radiation such as are encountered, for example, close to kilocurie sources of γ-emitters.

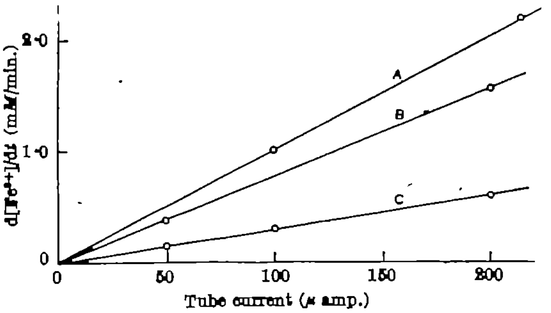
The method of radiation actinometry in most favour at present, the oxidation of ferrous ions in 0·8 *N* sulphuric acid solution, suffers from the disadvantage that the solution must remain effectively oxygen-saturated at all times for reproducible results to be secured, while the oxygen originally present in a solution in equilibrium with the atmosphere at room temperature is used up after a dose of about 50,000 r. has been administered[2]. At the dose-rates envisaged, this will happen in a matter of seconds. Moreover, at these high dose-rates there will not be time for the oxygen concentration within a solution to equalize itself by diffusion processes, so that if the release of energy within a given volume of solution is inhomogeneous, the elements of volume receiving the highest dose-rates will become deaerated before the remainder, with a consequent lowering of the overall yield before the solution as a whole has received an integral dose of 50,000 r.

These considerations have carefully to be borne in mind in any extension of the existing work on ferrous sulphate actinometry to high dose-rates, and it is apparent that in such studies means must be provided for starting and stopping the radiation virtually instantaneously, so that irradiation times of the order of seconds can be accurately measured.

Such facilities were recently made available to me by the Radiation Chemistry Group at the Atomic Energy Research Establishment, Harwell. Mr. John Milne, of this Group, designed and installed a magnetically operated device within the extension to the accelerator tube of the 2-million volt Van de Graaff generator, whereby a water-filled cell 9/16 in. deep, through which water was allowed to flow continuously, having a 1/16-in. aluminium window facing the electron beam, could be put into or withdrawn from the beam at a position 35 in. above the normal 1-mm. gold target by means of a switch operated at the control desk. The insertion of this cell cut down the X-ray intensity at the irradiation position just below the normal target by a factor of approximately 300.

By means of an auxiliary electric circuit, the beam current could be measured while the beam was impinging on the water target, and then adjusted to the desired value before the irradiation commenced. Corrections for the dose received during the preliminary build-up of tube current and voltage were made when necessary, but amounted to only about 1·5 per cent for an irradiation time of 15 sec.

Using this device, with irradiation times down to 10 sec., I have been able to show that the yield for the oxidation of ferrous ions in aerated 0·8 *N* sulphuric acid solution is independent of dose-rate up to the highest dose-rate obtainable from the machine, namely, approximately 100,000 r./min. The basis of the method is to study the rate of oxidation of ferrous ions in a 'Pyrex' cell of 2·8 cm. internal diameter and 8 mm. depth, totally filled with solution, as a function of the tube current in the machine at constant voltage. The dose-rate obtained from the machine was found, using a Baldwin 'Ionex' meter along the axis of the X-ray field, to be strictly proportionate to the tube current at constant voltage, while lateral surveys of the beam with the same meter showed that the geometrical distribution of dose-rate within the beam was not appreciably different at widely differing tube currents. The existence of a strictly linear relationship between the rate of oxidation of ferrous ions and the tube current was established at voltages of 1·5, 2·0 and 2·25 MV. (see graph), and with tube currents of 5–200 μ amp. Each of the points in the graph represents the average value obtained from at least four separate irradiations carried out under each set of conditions. At a tube current of 5 μ amp. and a voltage of 1·5 MV., the average dose-rate in this system corresponded to about 800 r./min.



Initial rate of increase of ferric ion concentration in aerated 0·8 *N* sulphuric acid solution as a function of the tube current in the Van de Graaff generator when run at 2·25 MV. (curve *A*), 2·0 MV. (curve *B*), and 1·5 MV. (curve *C*)

Similar studies have now been made by Ebert[3], using electron beams from the Van de Graaff generator at the Radiotherapeutic Research Centre, Hammersmith Hospital, London, who has found the initial yield for ferric ion production unaffected by dose-rate up to 3 million rep./min.; while Allen[4] reported similar results in the region 100–10,000 r./min. using X-ray beams from the 2-MV. generator at the Brookhaven Laboratory, New York.

In order to provide a further check on the absolute chemical yield at 800 r./min., experiments similar to those carried out previously[1] using the same machine were conducted. In these a cylindrical 'Perspex' irradiation cell of internal dimensions 30 mm. diameter and 3 mm. thickness, and 'Perspex' front wall thickness 6·4 mm., which could be regarded as effectively water-wall, was fixed at a position 18·5 cm. below the target, where the release of energy varied by no more than 8 per cent at all positions within the irradiated solution. The chemical change was compared with the integral dose within the solution by measuring the local dose-rate at many positions within the irradiated volume and carrying out appropriate integrations. As the Baldwin 'Ionex' meter used had been calibrated against an N.P.L.-standardized chamber to within ± 3 per cent, it was felt that this method was as accurate as any available. To ensure the presence during the ionization measurements of an electron atmosphere closely similar to that prevailing within the solution during the irradiations, the 'Ionex' meter was placed behind a 'Perspex' sheet of 6·4 mm. thickness; and the necessary small correction (< 0·3 per cent) for the absorption of the primary radiation within the solution was made using further data acquired with 'Perspex' absorbers of thickness from 3 to 13 mm. A value of the quantity *G* (ferric ions produced per 100 eV. expended in the solution) of 20·3 ± 1·0 was obtained, in further confirmation of my earlier work[1,2] and that of Hardwick[5], and Rigg, Stein and Weiss[6]. Values close to this have since been obtained by Ebert and Boag[3], and by Magat and Shapiro[7], and a figure of about 20 is now favoured by a great preponderance of evidence over that of 15·5 ± 0·3 obtained by Hochanadel and Ghormley[8]. The evident, if somewhat surprising, absence of any effect of dose-rate, or of any other source of irreproducibility so far detected in the system[1], signifies that the conditions were comparable in the various cases, and the reason for this discrepancy has still not come to light.

Similar studies were made using ceric sulphate solutions, which have the advantage of giving a yield independent of oxygen concentration[9], and the absolute *G* value for this reaction was estimated, by comparison with that for ferrous oxidation, as 3·0 at 59,500 r./min., in fair agreement with the figures of Hardwick[5] (3·2) and Milling, Stein and Weiss[10] (3·6), obtained at lower dose-rates. I am not entirely satisfied, however, as to the reproducibility of the behaviour of this system, as stated in an earlier publication[1]. Direct spectrophotometric analysis was used for both ferric and ceric ions, corrections being made for the variation of the extinction coefficient of ferric ion with temperature. The conditions for preparation of the solutions were identical with those described in my previous publications[1,2], with the exception that the water used was triply-distilled in an all-silica system.

Whereas the production of cerous ion was found to be proportional to dose up to 300,000 r. at 59,500 r./min., studies of ferrous oxidation at a dose-rate of 71,500 r./min. showed that the break in the oxidation – time plot at the point of oxygen depletion, which is normally observed to be sharp at low dose-rates[2], had become diffuse, signifying that conditions such as those described in the second paragraph of this communication had become operative. These conditions may partly explain the anomalously low yield obtained by me[2] and by Hardwick[11] using a General Electric 2-million volt X-ray unit; but doubtless the pulsed nature of the radiation in this case must, as Hardwick points out[11], also be taken into account.

Summarizing, it appears probable that chemical methods of dosimetry may be used for measuring continuous fluxes of X- or γ-rays up to the highest dose-rates at present envisaged.

Further experimental details of this work are included in an unclassified report from the Atomic Energy Research Establishment now in the press.

I am indebted to the Ministry of Supply for the tenure of a consultancy during which this work was carried out, to Dr. W. Wild and the members of the Radiation Chemistry Group at the Atomic Energy Research Establishment, Harwell, for the hospitality of their laboratories, and to Dr. F. T. Farmer and Mr. M. J. Day for a useful discussion on the accuracy of the physical measurements. Permission by Sir John Cockcroft to publish this communication is gratefully acknowledged. [Nov. 21.

# REDUCTION OF FERRIC ION IN AQUEOUS SOLUTION BY γ-RADIATION

By C. B. AMPHLETT

Atomic Energy Research Establishment, Harwell, Berks

ALTHOUGH the oxidation of dilute aqueous solutions of ferrous ion by ionizing radiation is a well-established fact, there is still some doubt concerning the reduction of ferric ion[1]. We have found that at sufficiently low acidities reduction may be effected[2], and that a steady state is set up with respect to ferrous and ferric ions if one irradiates either ferrous or ferric solutions, the position of the steady state depending upon the *p*H in sulphuric acid solutions[3]. Since publication of the latter work, further irradiations, particularly of ferric solutions, confirm this view, and in addition indicate that the initial reduction yield at low acidity is quite high.

Cobalt γ-radiation was employed under conditions similar to those previously described[3]. In addition to analysis of ferrous ion as the *o*-phenanthroline complex, direct estimation of ferric ion by its absorption at 304 mμ has also been employed in some cases; the two methods gave identical results. In order to avoid errors due to post-irradiation reactions arising from the slowness of the ferrous ion plus hydrogen peroxide reaction at low ferrous concentrations, all solutions were stood at room temperature for at least one hour between irradiation and analysis. The time of standing was varied up to six hours without any change in ferrous or ferric concentration greater than that found after one hour, and irradiations were carried out in a completely random order; the fact that the curves obtained still showed that a state is ultimately reached where no further oxidation or reduction can be detected appears to indicate that a true steady state is attained. The irradiation of solutions of *p*H > 2·5 presents some difficulty, since the second hydrolysis of ferric ion to $Fe(OH)_2^+$ becomes appreciable; this frequently leads to loss of ferric ion from solution, either by precipitation on the walls as $Fe(OH)_3$ or by formation of colloidal solutions. This leads to a depletion in strength of the original ferric solutions, and sometimes of the solutions of both ions formed on oxidation. In general, we have found it possible to carry out the oxidation of ferrous solutions up to *p*H 3·8 without serious difficulty; but in the case of ferric solutions above *p*H 2·5 frequent difficulties arise. All runs in which formation of $Fe(OH)_3$ had obviously occurred, or where ferrous solutions of low acidity had undergone aerobic oxidation, were rejected. Ferric solutions were prepared by oxidizing a ferrous solution with a slight excess of hydrogen peroxide, after which the excess peroxide was destroyed by boiling and the solution suitably diluted.

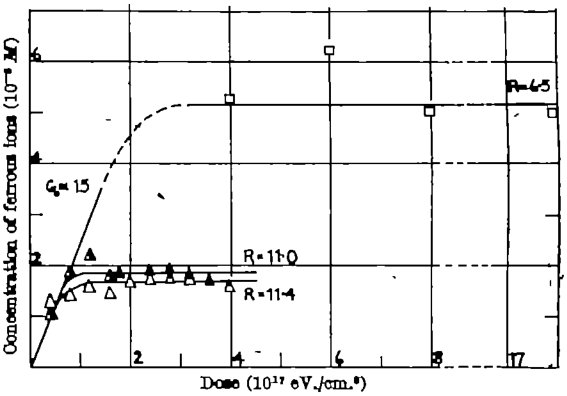

Fig. 1. Irradiation of ferric solutions in sulphuric acid in the presence of air, *p*H 2·46. □, $[Fe^{3+}]_0$ = 3·86 × $10^{-4}$ *M*; ▲, $[Fe^{3+}]_0$ = 2·11 × $10^{-4}$ *M*; Δ, $[Fe^{3+}]_0$ = 2·23 × $10^{-4}$ *M*

Fig. 1 shows the results obtained on irradiating three different ferric solutions in sulphuric acid, in the presence of air, at *p*H 2·46; the horizontal scale has been broken above 8 × $10^{17}$ eV./cm.$^3$ in order to conserve space. Reduction occurs, with an initial yield (ions reduced per 100 eV.) of approximately 15; a steady state is set up with the values of *R* (ratio of ferric ion to ferrous ion) given on the curves. Fig. 2 shows the result of irradiating a solution containing approximately equal proportions of ferrous and ferric ions at the same *p*H. Oxidation occurs initially, and a steady state is attained when approximately 77 per cent of the total iron is in the ferric state.

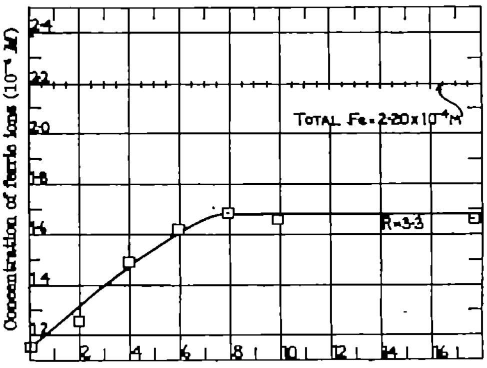

Fig. 2. Irradiation of solution containing both ferrous and ferric ions in sulphuric acid in the presence of air, *p*H 2·47. $[Fe^{3+}]_0$ = 1·05 × $10^{-4}$ *M*; $[Fe^{2+}]_0$ = 1·15 × $10^{-4}$ *M*

The initial reduction yield at this $p$H is comparable with the initial oxidation yield ($G_0 \sim 17$[3]), but its measurement presents some difficulty, owing to the fact that the steady state is soon attained. With higher total iron concentrations the difficulties attendant upon hydrolysis are greater, but more precision should be attainable at a suitably lower dose-rate. The reduction of ferric ion in oxygen-free and in hydrogen-saturated solutions has been reported by Weiss and his co-workers[4], the yield increasing with increasing $p$H and being much greater in the case of hydrogen-saturated solutions. These yields were obtained at constant dose, and not from the initial slopes of reduction curves; a rough calculation based on the dose and concentration which they quote suggests that these single points probably correspond to steady-state values, so that their yields may be low. Haissinsky *et al.*[5] quote a value of $G_2 = 0{\cdot}07$ for the reduction by X-rays in $0{\cdot}8\ N$ sulphuric acid, but this is probably within the limits of experimental error; under these conditions the steady state corresponds to complete oxidation, or nearly so, and would be attained very rapidly on reduction.

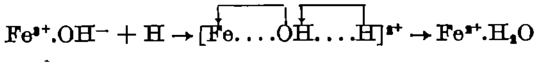
In the ferrous–ferric system under the above conditions of $p$H, oxidation may be effected by hydroxyl radicals, hydroperoxide radicals ($HO_2$) and hydrogen peroxide, and reduction by hydrogen atoms and by $O_2^-$ ions; the $HO_2$—$O_2^-$ couple is expected to play an important part in the balance between oxidation and reduction[3,6,7], and the hydrolysis of ferric ion to $FeOH^{2+}$ must also be considered. Baxendale *et al.*[8] have given evidence to support the view that the $p$H-dependence in the $Fe^{2+} + H_2O_2$ reaction arises from a combination of the dissociation of hydroperoxide radicals with hydrolysis of ferric ions. In the irradiation reaction a further consequence of the hydrolysis is possible, namely, that the hydrogen atom reduction of ferric species may be more effective for the hydrolysed ions than for the aquo-ferric ion (or the sulphate complexes in strong solutions of sulphuric acid). Both the reactions:

$$Fe^{3+}_{aq.} + H_{aq} \rightarrow Fe^{2+}_{aq.} + H^+_{aq.} \qquad (1)$$

and

$$\left.\begin{array}{l} FeOH^{2+}_{aq} \\ Fe^{3+}.OH^-_{aq} \end{array}\right\} + H_{aq.} \rightarrow Fe^{2+}_{aq.} \qquad (2)$$

are quite exothermic[6], but (2) may be favoured by entropy considerations. In the first case, the completed hydration shell may act as a barrier to electron-transfer between the hydrogen atom and the central ion, whereas in (2) the reaction may effectively occur at the boundary of the shell, resulting in completion of the shell and attainment of a much more symmetrical configuration. The transfer of electrons between ferrous and ferric ions through the outer electronic orbits of hydroxyl ions has been postulated to explain the colours obtained when ferrous hydroxide precipitates are oxidized in air[9], and it is possible that a similar mechanism operates in (2) above to produce a net electron transfer from hydrogen to ferric ions. The calculation of the energetics of this step is made difficult by the fact that the reaction is assumed to occur within the complex, whereas most of the measured and calculated heats and entropies refer to the separation of the complexing ion from the central ion. The process may be written schematically as follows:



$$Fe^{3+}.OH^- + H \rightarrow [Fe\ldots OH\ldots H]^{2+} \rightarrow Fe^{2+}.H_2O \quad (2a)$$

in which the other five co-ordinated water molecules are omitted, and the arrows indicate the direction of electron-flow.

Such a process may readily be envisaged in the absence of dissolved oxygen, and is, in fact, formally analogous to the back-reaction in the photo-induced reduction of water by ferrous ion[10]. It is usually assumed that, in the presence of oxygen, all the hydrogen atoms are removed by reaction (3):

$$H + O_2 \rightarrow HO_2. \qquad (3)$$

This appears to be beyond doubt at acidities greater than $0{\cdot}1\ N$, where the change from the oxygenated yield to the oxygen-free yield occurs at a point corresponding to the stoichiometry $\Delta[Fe^{2+}] = 4[O_2]$, without appreciable production of hydrogen. Although it is thus clear that (1) is negligible compared with (3), there is no evidence to suggest that similar considerations apply to (2) and (3) at higher $p$H. Owing to the more complex nature of the oxidation curve at higher $p$H, and to the changing value of the ratio of oxygenated to oxygen-free yield, such evidence would probably best be sought by measuring the consumption both of ferrous ions and of oxygen, as well as production of hydrogen, in an irradiation. It is suggested that, at sufficiently high $p$H, (2) may compete appreciably with (3); since the hydroperoxide radical can oxidize three ferrous ions, while $O_2^-$ reduces only one ferric ion, there will be a net gain in reduction so far as the effect of the hydrogen atoms originally formed are concerned. The decrease in initial oxidation yield in the presence of excess ferric ion at high $p$H might be due in part to (2), which would then also be partly responsible for the fall in yield as oxidation proceeds. Competition between ferric species and dissolved oxygen for hydrogen atoms would not lead to a dependence of initial oxidation yield upon initial ferrous concentration, but to an initial reduction yield dependent upon initial ferric concentration.

It will be noted that the value of the ratio of ferric to ferrous ion obtained by oxidation of a ferrous solution ($R = 3{\cdot}3$) is appreciably less than that from reduction of a corresponding ferric solution ($R = 11{\cdot}2$), and that in the latter case the value appears to vary with initial ferric concentration; we believe that these differences lie outside the limits of experimental error. An inspection of earlier results (ref. 3, Table 3) shows a similar behaviour at $p$H 2·1, although here the difference is less. This appears to indicate that the steady state obtained on reduction differs from that produced by oxidation, that is, that the ferrous–ferric couple is not thermodynamically reversible with respect to hydrogen atoms and hydroxyl radicals; this would have important consequences for the concept of equivalent reduction potential[11]. The lower value of $R$ obtained at higher initial ferric concentrations may be connected with the dependence upon concentration which would arise if reaction (2) is operative. [Aug. 20.

### Origin of the Solar Corona

If the distributions of electron density and temperature in the sun's atmosphere are known, thermal emission at any frequency in the radio spectrum may be calculated. Conversely, properties of the atmosphere may be deduced from the observed thermal emission spectrum[1]. In the range above 600 Mc./s. the observed level of radiation can be correlated with visible sunspot area. Excess radiation appearing with spots has been interpreted[2] as thermal emission from very hot ($10^7$ ° K. or more) high-pressure (perhaps a hundred times that of surrounding regions) regions above the sunspots. There is optical evidence[3] of similar regions, and the good agreement between theory and radio observations lends weight to the suggestion.

If these hot regions do exist, they are a likely source of at least some of the energy needed to maintain the corona. To investigate this possibility, a statistical analysis was made of measurements of solar radio noise at frequencies between 600 Mc./s. and 9,400 Mc./s. on most days over a period of several years. The total radiation was separated into two components—one appearing with sunspots (but not necessarily disappearing with them) and a residual or basic component. The intensities of the components were then used for determining corresponding volumes of gas at suitable temperatures and pressures. The results may be summarized as follows:

(1) The sunspot component diminishes less rapidly than the dying spots, and remains more than a month after the spots have vanished. Previous observational evidence of this effect in particular cases is available.

(2) Previous determinations of the basic component are too high. They were obtained[4] by plotting daily values of radio noise against sunspot area as in Figs. 1 and 2 for 600 Mc./s. where a basic component of about $5 \times 10^5$ ° K. is indicated. The persistence of radiation, as indicated above, results in many plots of high noise and very low area; for this and other reasons the basic component found is too high. The errors are corrected and correlation improved by using rotational mean values of noise and area, reducing the value to about $2 \cdot 8 \times 10^5$ ° K. If allowance for dead spots is made, as in Fig. 3, the value falls further to $1 \cdot 7 \times 10^5$ ° K. The corresponding reductions at 1,200 Mc./s. are even larger (by factors of 2·3 and 4·7 respectively). In the investigation, arithmetic rather than graphical methods were used, and care taken to avoid errors due to the statistical processes.

This result explains the reported large fall in the basic component during 1950[5] as merely a fall in the sunspot component due to a prolonged decrease of sunspot activity.

(3) These and earlier[2] results suggest that volumes of very hot high-pressure gas appear with sunspots, mainly (perhaps entirely) near the spots, and remain after the spots have vanished, spreading and merging with the surrounding cooler gases. During the period 1947–51, these gases at all times comprised most of the corona and were formed at a rate capable of completely replacing the average (Allen – van de Hulst) corona in a few days. They are suggested as the principal source of the corona.

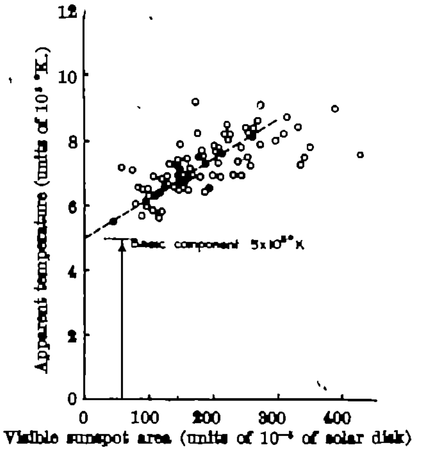

Fig. 1

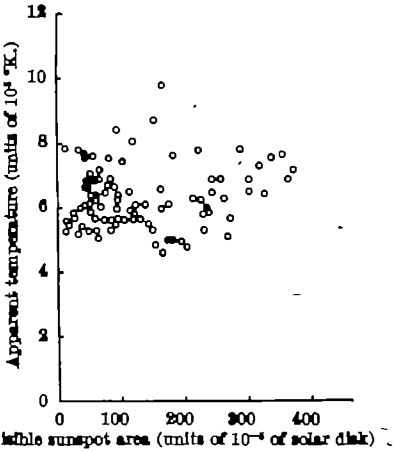

Fig. 2

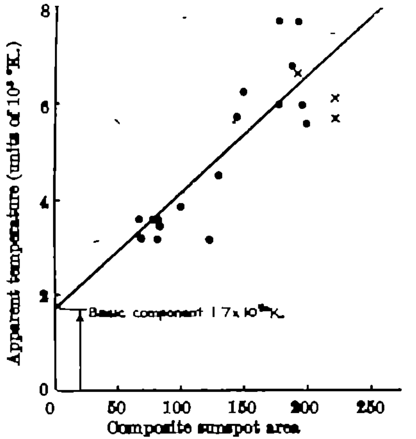

Fig. 3

Figs. 1–3. Radio noise plotted against sunspot area.
(1) Daily values for the period August–November 1947.
(2) Daily values for the period January–July 1950.
(3) Average value of radio noise for a given solar rotation plotted against a composite spot area $0 \cdot 4A_0 + 0 \cdot 3A_{-1} + 0 \cdot 2A_{-2} + 0 \cdot 1A_{-3}$, where $A_{-n}$ is the average spot area $n$ rotations earlier. The period concerned is December 1949–April 1951

It is estimated that if sunspots were entirely absent for some months and no other additional source of energy became available, the corona would diminish to one-tenth the extent, or one-third the electron density, observed during relatively quiet periods in 1948.

The results may provide a step towards an understanding of coronal heating and evidence against some existing theories, notably accretion theories[6]. Full details will be published elsewhere.

## Distances of the Magellanic Clouds

THE distances of 26 and 23 kiloparsecs derived by Shapley[1] for the two Magellanic Clouds depend upon assuming the same absolute magnitudes for the Cepheid variables in the Clouds and in our own galaxy. The absolute magnitudes of the galactic Cepheids are still subject to considerable uncertainties, and it would be more satisfactory to use as distance-indicators the *RR* Lyræ variables (with periods less than 1 day) the absolute magnitudes of which are known more accurately and which are found in great abundance in our own galaxy. Very few such variables, however, have been found in the Small Cloud[2], and none so far has been reported in the Large Cloud.

A search for *RR* Lyræ variables in the Clouds was begun soon after the installation of the Radcliffe 74-in. reflector. *NGC* 1866, one of the largest and brightest clusters in the Large Cloud, was first selected as a region for investigation, but failed to reveal any variables of *RR* Lyræ type; instead, surprisingly enough, some classical Cepheids turned up[3]. It is now possible to report successful searches for *RR* Lyræ variables in three clusters as follows:

| (1) Cluster | (2) Region | (3) No. of variables | (4) Short period | (5) $m_{pg}$ | (6) Deduced distance (kpc.) |
|---|---|---|---|---|---|
| *NGC* 121 | Edge of Small Cloud | 4 | 3 | 18·6 | 44 |
| *NGC* 1466 | Edge of Large Cloud | 28 | 21 | 18·7 | 44 |
| *NGC* 1978 | Within Large Cloud | 4 | 2 | 18·7 | 42 |

*NGC* 121 lies within and *NGC* 1466 lies just outside the faint extension borders found by Shapley[4]. Column (3) gives the total number of variables so far found on Radcliffe plates apparently associated with these clusters; column (4) gives the number of variables so far shown to have short periods. Column (5) gives the mean apparent photographic magnitude of the stars in column (4) as derived from comparisons with the Selected Areas 68 and 94, at the same altitude. The comparisons are subject to uncertainties partly because of the large change in azimuth required, and partly because old magnitudes in Selected Area 94 had to be used. The deduced distances in column (6) depend on assuming $M_{pg} = 0$ for these variables, and on a correction for interstellar absorption amounting to 0·31 mag. cosec *b*, as given by Oort[5].

These newly discovered faint variables therefore indicate that the distances of the Magellanic Clouds are larger than believed hitherto. A precise redetermination must await revised magnitudes in Selected Area 94. The uncertainty in the distances given in column (6) must be of the order of 25 per cent, mostly arising from the difficulty of comparison with the Selected Areas, but partly also from the uncertainty in the assumed absolute magnitude of *RR* Lyræ variables. The indications are that an error in the comparison is likely to have underestimated the distances. The conclusion supports the results reported by Baade for the Andromeda nebula at the International Astronomical Union meeting in Rome, 1952.

The increased distance, which has been supported by Shapley[6], implies an increased luminosity for classical Cepheids and hence a change in the shape of the period – luminosity curve. Such a change in shape, especially at about $P = 1$ day, was already suggested by the variables in the Sculptor System[7], which showed a difference of about 1 magnitude between $P = 1$ day and $P = 0·5$ day.

## Travelling Disturbances in the Ionosphere: Diurnal Variation of Direction

THE detection of travelling disturbances in the *F*-region of the ionosphere has already been reported[1]. In the last-mentioned paper, it was stated (p. 221): "It has not yet been possible with the limited data available to detect any definite diurnal variation". This has been interpreted in some more recent publications by other authors as implying that there is no diurnal variation.

Since the publication of the original papers, more observations of greater accuracy and extending over a greater part of the day have provided definite evidence of diurnal variation in the direction of horizontal movement. This is most marked in the month of June. The accompanying graph shows the median values of all directions observed for each hourly interval for all days of June in each of the three years 1950–52. Each point is the median of the appropriate number of values listed in the table.

It will be seen that there is a similar trend in the three years, the direction of movement changing from approximately 50° (E. of N.) at 0930 to 15° at 1430. In addition, some recent night observations, though not sufficient for definite conclusions, suggest that there is consistently an east–west component of

NUMBER OF INDEPENDENT OBSERVATIONS OF DIRECTION

Diurnal variation of direction of movement in June

movement present at night, in contrast with the consistently west–east component present in the daytime, indicating a significant change in direction of travel as between day and night. These observations are being extended, and the results and implications will be discussed more fully elsewhere.

This work has been carried out in the Electrical Engineering Department of the University of Sydney as part of the investigations of the Radio Research Board of the Commonwealth Scientific and Industrial Research Organization, and is published with the consent of the Executive. ## Beta-Spectrum of Radium E

The shape of the β-spectrum of radium E differs from the Fermi allowed form. It has been investigated thoroughly; but there are many effects which usually distort the spectrum in the low-energy region[1]; for example, straggling and back-scattering in the source, electron scattering in the spectrometer, distortion introduced by the detector and many others.

Different ways of eliminating these disturbances have been tried lately; for example, Waltner and Rogers[1] observed the beta-tracks in a cloud chamber, Langer and his co-workers[2] used a windowless Geiger counter. Nevertheless, the results obtained by different authors showed marked discrepancies in the low-energy region.

We tried to solve the problem by preparing a very thin source and using electron-sensitive nuclear emulsions (Ilford *G*5) as a detector. The intensities were found by counting the β-tracks recorded in a magnetic lens spectrograph. In all, 35,000 tracks were counted. The shape of the spectrum was investigated down to 4·6 keV. Very thin sources were prepared by a volatilization method. They were suspended on a 'Zapon' film which was coated with an extremely thin layer of gold to increase the conductivity. The whole thickness of the source, 'Zapon' and gold was not greater than 4–4½ μgm./cm.[3]. From an examination of images obtained in the spectrograph, it was found that the uniformity of the sources (1·1 mm. diameter) was satisfactory. The electron tracks were recorded on the surface of the emulsion, which therefore could be only 25 μ thick. During the processing of the emulsion, great care was taken to obtain a clear surface with reduced background grains. For the lowest energy the 'tracks' contained one grain only. In this region, elimination of the background was done by the measurement of the grain density in the vicinity of the spot. In some cases, for better separation of overlapping grains, the emulsion was resoaked in water before microscopic examination. Nuclear emulsions were used to focus the spectrograph and also in the investigation of the relation between the energy and the number of grains.

Analysis of the geometrical distribution of intensity in the images of the source at different energies showed that it was possible to take into account the tracks recorded in a wide zone of each image. It was shown that the measured intensities did not depend much on the position of counting area (zones).

Figs. 1 and 2 represent the results concerning the energy and momentum distribution in the radium E spectrum. The energy distribution curve probably cuts the $I(E)$ co-ordinate. From the experimental points it is evident that below 50 keV. the distribution function cannot be interpreted in terms of $(E-E_0)^4$.

Details of the method of preparation of source and the investigation of the relation between the number of grains and energy below 30 keV. will be given shortly in *Acta Physica Polonica*.

## A Simple X-Ray Micro-beam Technique

A simple method has been devised to enable X-ray diffraction photographs to be obtained from a single plant cell the size of which is of the order of 10 µ × 10 µ × a few mm. long. Although details of methods using micro-focus tubes and micro-beams have been published, they are not suitable in this instance because of the low diffracting power of cellulosic materials.

Small lead-glass capillaries are not satisfactory because scatter from the edges of the aperture is great enough to obscure diffraction from the specimen. Using metal pin-holes, it is extremely difficult to make and adjust the necessary secondary aperture, so that satisfactory results are never obtained.

The system in use at present (Fig. 1) consists of two tilted metal plates mounted over the exit aperture of a collimator with two ¼-mm. pin-holes 50 mm. apart. The geometry of the system is made such that the corners of the plates define the beam (30 µ wide) while the edges prevent scatter from these corners reaching the photographic film. Because long specimens are used and because we are only concerned with the equatorial arcs, only one pair of plates is used; however, a second pair mounted at right-angles to the first could be used if it became necessary either to use a square beam or to remove the meridional streak, or both. The large entrance aperture allows the whole of the X-ray source of normal dimensions to be used.

The specimen is mounted directly on the collimator; to ensure that it will be in the X-ray beam, light is passed through the whole collimator and the specimen adjusted, under a binocular microscope, to be in the light beam. The collimator carrying the specimen is then transferred to a normal flat-film camera. A Geiger counter and rate-meter are essential for lining up the collimator with the X-ray source.

## Resonance Absorption in Liquid Methyl Palmitate and Methyl Stearate in the Microwave Region

In a previous communication in *Nature*[1], it was pointed out that dielectric measurements on solid methyl palmitate, in the microwave region, showed features which were difficult to explain on the basis of a purely relaxation type of loss, and it was suggested that resonance absorption was occurring at some frequency in this region. This conclusion was criticized[2], and it must be admitted that the evidence was not entirely convincing.

Measurements have since been made on stearic and palmitic acids and their methyl and ethyl esters at temperatures ranging from the melting points to about 30 or 40 deg. C. above the melting points. The measurements at 3·2 cm. and 1·26 cm. were obtained by the Roberts – von Hippel method, and the measurements at the other wave-lengths, 17, 10, 9, 8, 6·5, 5, 4·5 and 4 cm., were obtained by a phase and amplitude balance method using coaxial-line equipment. This method is a development of one described by me elsewhere[3] and is similar to that described by Branin and Smyth[4]. The wave-lengths 5, 4·5 and 4 cm. were obtained by harmonic generation.

The acids show a fairly small loss in the microwave region, with a suggestion of a small relaxation loss near 3 cm. wave-length. The loss in the methyl and ethyl esters was much greater than in the acids. The curves of $\epsilon'$ and $\epsilon''$ as functions of frequency are, in the case of the ethyl esters, normal relaxation loss curves with a spread of relaxation times. The measurements on ethyl palmitate are shown in Fig. 1. Ethyl stearate gives similar curves. The results for

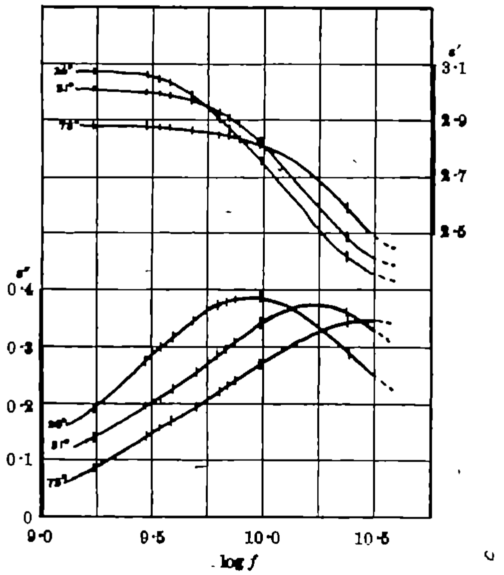

Fig. 1. Ethyl palmitate

methyl palmitate are shown in Fig. 2, and there is a decided irregularity in the ε' curve and a fairly pronounced shoulder in the ε'' curve. These irregularities occur at about 6,000 Mc./s., and this frequency shows little or no change with temperature; but the irregularities diminish as the temperature rises and the curves then tend to become normal relaxation curves with a spread of relaxation times. The curves for methyl stearate are similar to the palmitate curves.

The dotted curves in Fig. 2 indicate the values of ε' and ε'' which would be expected from a purely relaxation process. If we plot the difference between the dotted curves and the experimental curves, we obtain the curves *P* and *Q*, which are very suggestive of a resonance absorption. There is some latitude in the choice of the dotted curves; but any reasonable choice will lead to curves which will not differ very much, in shape, from *P* and *Q*.

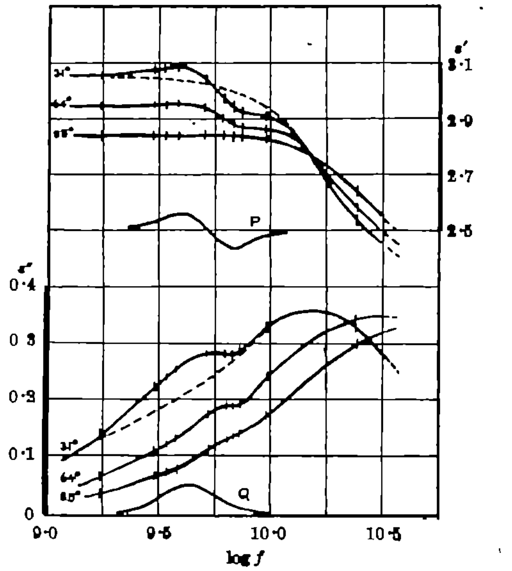

Fig. 2. Methyl palmitate

The central frequency of this resonance absorption is approximately 6,000 Mc./s. and is, within experimental error, the same frequency as obtained with methyl stearate. This frequency is 100–1,000 times smaller than the resonance frequency which one would expect for the type of resonance absorption discussed by Frohlich[5]. Rotation of the molecule around the long axis would give a frequency of the right order of magnitude when allowance is made for the effect of the retarding potential barriers[6].

The resonance absorption decreases and finally vanishes at temperatures about 40 deg. C. above the melting point. It is well known that many long-chain compounds show a state of short-range order in which the molecules tend to lie parallel to each other. This condition is most in evidence near the melting point, and the order diminishes as the temperature rises. It seems likely that this short-range order is necessary for the existence of this form of resonance absorption. If this absorption is due to rotation of the molecules around the long axis, then this can be understood. When the temperature rises and the molecules begin to twist and crumple about the C—C bonds[7], then rotation around the long axis would not occur.

It is a little surprising that the ethyl esters do not show the same effect as the methyl esters, though the ethyl group, being larger than the methyl group, probably projects farther from the axis of the molecule and may give rise to a steric hindrance to rotation.

Thanks are due to Prof. J. E. Roberts for his interest in this work and for the facilities provided; and also to Messrs. Unilever, Ltd., for providing pure specimens of the acids and the methyl esters.

## An X-Ray Diffraction Study of the Transformation of Retained Austenite by Fracture

During an investigation of the structure of a hardened 1½ per cent chromium steel, the presence of a small amount of retained austenite was observed in the microstructure. Examination of this material by the glancing-angle X-ray diffraction technique revealed retained austenite on a surface mechanically polished and etched for micro-examination, whereas retained austenite could not be found on the surface of a fracture produced by fatigue, or on a freshly produced brittle fracture surface.

That the austenite was introduced during preparation of the microspecimen seemed unlikely owing to precautions taken to avoid overheating in grinding and polishing and from the appearance of the microstructure. This hypothesis was finally disproved by further X-ray pictures showing the presence of retained austenite: (1) on a small flat prepared on a brittle fracture by lightly hand-polishing to a depth of several thousandths of an inch below the fracture surface; (2) on both types of fracture after removing metal from the fracture surface by deep-etching, the largest proportion of retained austenite being observed for the deepest etch.

It would appear impossible to interpret the evidence except by assuming a complete (within the experimental accuracy) transformation of retained austenite at fracture surfaces, presumably as a result of highly localized shear deformation at the position of fracture.

B. L. Averbach, S. G. Lorris and M. Cohen, in their paper on "Stress-Induced Transformation of Retained Austenite in Hardened Steel"[1], have also observed that retained austenite contained in a specimen of hardened 3½ per cent nickel steel transforms completely at a fracture, and, incidentally, that an inverse relation appears to exist between strain and the amount of retained austenite remaining. We do not know of any reference to this phenomenon occurring in a 1½ per cent chromium steel. It is considered likely that other types of hardenable steel which contain retained austenite after hardening will exhibit a similar transformation.

These examples of the complete transformation of retained austenite on fracture surfaces are of particular importance to the X-ray crystallographer in that they throw doubt on the validity of the usual contention that newly fractured surfaces are most suitable for X-ray diffraction tests on bulk metal specimens. Grinding, polishing, etching, electropolishing, machining and filing are all well known to introduce specific dangers of possible errors of interpretation. Our observations indicate that even freshly broken surfaces may show a structure or texture which is not typical of the bulk material. It is imperative that the crystallographer should consider sample preparations most carefully and treat every particular experiment on its merits.

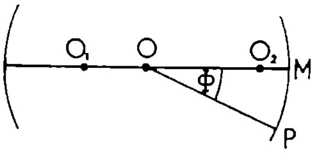
## A New Method of Light Microscopy

THE method described by Prof. A. Wilska[1] appears to be a special case of phase-contrast, generally known as 'amplitude-contrast'. Although not usually employed with fixed phase-contrast objectives, it frequently crops up in variable phase-contrast and interference systems. Oettlé[2], for example, used it in his experiments with a variable amplitude and phase microscope. The basic theory can be simply explained by a vector treatment similar to that given in detail elsewhere[3]. Object details can be represented by points in or on the well-known vector circle, centre $O$, radius $OM$. In conventional microscopy, the origin remains at $O$ and transparent phase-changing details such as $P$, which lie on the circumference of the circle, are all equidistant from $O$ and appear with equal intensity, $OP^2$ ($= OM^2$), so that contrast is zero.

The object of phase-contrast and interference microscopy is to shift $O$ to some new position so that points on the circumference will no longer be equidistant from the origin, but will appear with intensities depending on $\varphi$, the phase change introduced by the detail. In ordinary phase-contrast this is achieved by rotating the vector $OM$, which represents the direct light, and changing its amplitude, that is, by altering the phase and intensity of the direct or diffracted components. We can, however, shift $O$ by changing only the amplitude of $OM$ without rotation. In this case pure amplitude-contrast is obtained and the new origin lies somewhere on $OM$. In Prof. Wilska's second method, the intensity of the direct light is reduced to about 1/12. The amplitude is thus $1/\sqrt{12}$ or 0·29. The new origin is $O_2$, where $O_2M = 0{\cdot}29$, $OM$ being taken as unity. The background intensity is now $O_2M^2$, the detail intensity $O_2P^2$. Thus for all except very small phase changes, the image detail will be brighter than the background and it will not be possible to distinguish phase advances from phase retardations. If all the direct light were absorbed, the new origin would coincide with $M$, giving central dark-ground illumination in which theoretically all details will be bright on a black background.

In his first method, Prof. Wilska absorbs 50 per cent of the diffracted light. In this case the new origin will be at $O_1$, where $O_1M = \sqrt{2}$. This is an example of $B$-type amplitude contrast[3,4]. The detail intensity $O_1P^2$ is now always less than the background intensity $O_1M^2$, so that dark contrast occurs. However, for small phase changes, $O_1P$ is very nearly equal to $O_1M$, so that contrast is inherently poor, and becomes worse as the transmission of the diffracted light decreases, that is, as $O_1$ moves farther away from $M$. This latter method is therefore only useful for rather refractile objects such as thick cells and fibres.



The halo effect[4] is inherent in all phase-contrast and interference systems in which there is incomplete separation of the interfering beams (in this case the direct and diffracted components). It becomes much more conspicuous with heavy absorption of the direct light and is particularly noticeable in Prof. Wilska's photographs, for example, around the sperm tail in Fig. (c) and the edge of the epithelial cell in Fig. (e). The halo will be much less obvious in $B$-type contrast as observed by Prof. Wilska, and it will also depend on the width of the annular ring in the objective, which determines the degree of overlap between direct and diffracted light.

These considerations are based on the assumption that it is possible to affect the transmission of the light wave without altering its phase. If the partly absorbing layer introduces a phase change, then some degree of phase-contrast will occur and $O_1$ and $O_2$ will no longer lie on $OM$. In Prof. Wilska's first method the phase of the direct light will be advanced, and in the second case it will be retarded, relative to the diffracted light. This will give rise to positive and negative phase-contrast respectively, thus heightening the effects already predicted.

Prof. Wilska's letter should be useful in directing the attention of microscopists to the value of amplitude-contrast and central dark-ground illumination in some cases. His photographs show that excellent results can be obtained by very simple means.

---

Without criticizing the vector treatment of amplitude and phase-contrast microscopy kindly given by Dr. Barer in his comment on my letter[1], I would like to make the following comments: (1) Using my second method, phase-advancing objects appear darker than the background. The soot layer appears to cause a considerable phase retardation in addition to the absorption. (2) If the absorbing annulus is made substantially darker, the resulting image becomes peculiarly glossy and too unsharp to be of any value. Thus the "central dark-ground illumination" does not seem to be very promising in this connexion. (3) According to Oettlé[2], as well as from my own observations, ordinary negative phase-contrast methods do not produce images comparable with those of positive phase-contrast in clarity. The inherent haziness and glare of the negative phase-contrast picture may be due entirely to the light reflected from the phase plate and converged back to the area under observation. Due to the reflectivity of absorbing annuli evaporated by ordinary means, this additional surface illumination may reach higher values than the light passing the objective annulus. My method does not suffer from this in the same degree since the reflectivity of soot is small.

## Ability to smell Solutions of Potassium Cyanide

It has been known for many years that some individuals are unable to smell hydrogen cyanide, and the possibility that this inability may be genetically controlled was mentioned at a recent conference on the origin and evolution of man[1]. A short time ago our attention was directed again to this phenomenon, and we have since used a simple method of ascertaining the frequency of the inability to smell hydrogen cyanide among the white population of Australia and carried out a preliminary study of the mode of inheritance of this character.

The sample of the adult population comprised 244 individuals ranging in age from sixteen to sixty. The method of testing finally adopted consisted of presenting alternately tubes containing respectively 5 ml. distilled water and 5 ml. 20 per cent potassium cyanide soaked into cotton-wool. The tubes were stoppered between tests. Fresh tubes were made up at the beginning of each day. Subjects were asked to state if they could smell anything in either tube. Those that could were classified for the strength of their response on a subjective five-point scale. Independent observers achieved similar results using this method. Subjects whose response was doubtful or negative were retested after a rest of several minutes. Non-smeller individuals were retested in nearly all cases on subsequent days.

There is a striking difference between the sexes in the incidence of non-smellers when this method of testing is used, 24 out of 132 males, and 5 out of 112 females being unable to distinguish the cyanide tube from that containing distilled water. Of the remaining individuals tested, 31 males and 26 females could distinguish the smell from the potassium cyanide tube only faintly, but all were able to pick out the correct tube when retested. All the other subjects could distinctly and immediately recognize a smell in the tube containing the cyanide, though the nature and strength of the response varied considerably from person to person. The proportion of non-smeller males and females suggests that the inability to smell is a sex-linked recessive. The observed frequency of females (4·46 per cent) corresponds closely with what would be expected (3·33 per cent) from the observed number of males (18·2 per cent) if sex-linkage were operating. The difference between the frequency of the recessive gene calculated from the number of non-smeller males and that calculated from the number of non-smeller females does not differ significantly from zero when tested by the method of Snyder[2].

In an attempt to examine further the possibility of sex linkage, we have tested 61 families containing two or more children older than ten years. The 122 parents of these children are included in the larger sample of 244 individuals discussed above. Table 1 gives the number of smellers and non-smellers among the offspring in various mating groups.

Table 1

| Group | No. of families | Parents | | Children | | | |
|---|---|---|---|---|---|---|---|
| | | Males | Females | Male | | Female | |
| | | | | S. | N.S. | S. | N.S. |
| 1 | 45 | Smeller | Smeller (expected) | 53<br>(48) | 4<br>(9) | 54<br>(54) | 0<br>(0) |
| 2 | 12 | Non-smeller | Smeller (expected) | 11<br>(11) | 2<br>(2) | 13<br>(13) | 3<br>(3) |
| 3 | 4 | Smeller | Non-smeller (expected) | 2<br>(0) | 2<br>(4) | 4<br>(4) | 0<br>(0) |
| 4 | 0 | Non-smeller | Non-smeller | — | — | — | — |
| Total | 61 | | | 66 | 8 | 71 | 3 |

Though the number of families tested so far does not enable a decisive answer to be given by gene frequency analysis, the results indicate that a sex-linked recessive gene is possibly involved in the control of the ability to smell hydrogen cyanide. There is a deficiency of non-smeller males in group 1 and there are two exceptions in group 3. In this latter group all male children should be non-smellers. One of these children is a very doubtful smeller, but the other has no difficulty in detecting the presence of cyanide. One explanation of such discrepancies may be the operation of other genetic factors which

Table 2

| No. of. families | Parents |  | Children |  |  |  |
|---|---|---|---|---|---|---|
|  |  |  | Weak |  | Strong |  |
|  | Males | Females | ♂ | ♀ | ♂ | ♀ |
| 10 | Strong | Strong | 2 | 2 | 9 | 10 |
| 9 | Weak | Strong | 4 | 4 | 5 | 6 |
| 14 | Strong | Weak | 9 | 10 | 9 | 6 |
| 12 | Weak | Weak | 11 | 11 | 4 | 5 |
| Total 45 |  |  | 26 | 27 | 27 | 27 |

affect the degree of manifestation of the smeller characteristic. We have demonstrated that other factors are involved for people who are classified as smellers by grouping individuals into 'weak' and 'strong' categories. Table 2 gives the distribution of 'weak' and 'strong' smellers among the 45 families in group 1.

There is no difference between the sexes for the strength of response of individuals who are smellers; but there is a highly significant tendency for parents who are 'strong' smellers to have children who are 'strong' smellers, and parents who are 'weak' smellers to have children who are 'weak' smellers ($\chi^2 = 16.173$ with 3 degrees of freedom; $0.001 < P < 0.01$).

Any hypothesis which seeks to explain the inability to smell solutions containing potassium cyanide in terms of a sex-linked recessive gene must take into account, therefore, the possibility that some smeller individuals may be wrongly classified because of the intervention of other genetic factors affecting the strength of the response.

A fuller account of this work will be published elsewhere.

## Serum Iron and Iron-binding Capacity in the South African Bantu

Excessive amounts of iron are frequently present in various organs and tissues of adult South African Bantu[1]. Among these people, the iron intake is often high, as much as 200 mgm. per diem[2]. Further, occasional high values for serum iron have been reported among the Bantu of Bechuanaland[3]. In view of these facts, serum iron-levels, iron-binding capacity and other data have been determined in groups of adult Bantu from different regions of Southern Africa.

The Johannesburg group, of ages up to sixty years, were from a local non-European hospital; they were either on the staff or were suffering from complaints unlikely to influence levels of serum iron or iron-binding capacity. The Bantu males, 18–40 years, were workers from different territories, passed as medically fit for service in the gold mines. The European controls were members of the staff of this Institute.

Means, Standard Deviations and Ranges of Serum Iron and Total Iron-binding Capacity in Different Bantu Groups

|  | Remarks | Serum iron ($\gamma$ per 100 ml.) | Total iron-binding capacity ($\gamma$ per 100 ml.) |
|---|---|---|---|
| Bantu females | Johannesburg area | 180 ± 40 (20)* (60–215) | 335 ± 55 (17)* (240–435) |
| Bantu males | Johannesburg area | 230 ± 75 (14) (110–380) | 385 ± 50 (14) (320–475) |
|  | Group *A*† | 105 ± 45 (39) (15–225) | 375 ± 70 (39) (225–590) |
|  | Group *B*‡ | 285 ± 100 (68) (110–550) | 520 ± 90 (42) (395–830) |

* Number of subjects.

† Bantu with serum iron and total iron-binding capacity within normal range; Pondoland (13), N. Transvaal (Bapedi) (14), Tanganyika (12).

‡ Bantu with increased serum iron and total iron-binding capacity, significantly higher than those of group *A*; Mozambique (44), Angola (12), Nyasaland (12).

Samples were taken by venipuncture between 9.30 and 11.30 a.m., the usual precautions being taken to prevent contamination with iron. Serum iron was determined using the thioglycollic acid method. The iron-binding capacity was determined by the method of Rath and Finch[4]. The total iron-binding capacity was obtained by adding the value for serum iron to the iron-binding capacity. The difference between duplicates was never more than 10 per cent; all figures, therefore, including means and standard deviations, are given to the nearest 5 $\gamma$.

Our results for control groups of Europeans were in close agreement with values reported by other workers[4,5].

Several of the individual values obtained for serum iron and total iron-binding capacity were higher than any reported for such diseases as idiopathic hæmochromatosis or transfusional siderosis[4]. In no case has serum iron saturation been found. Further, among the Pondos and Bapedi examined, a few very low values for serum iron were obtained, which were, however, consistent with normal hæmoglobin levels.

Whether or not our groups with high serum iron and total iron-binding capacity values correspond with groups having high iron intakes, or displaying abnormal deposition of iron, is being investigated.

This communication is published by permission of the South African Council for Scientific and Industrial Research. For co-operation and help, we are grateful to Drs. R. C. Pearson and R. M. Yeo, and to Messrs. J. Lub and E. Rogers, of the Witwatersrand Native Labour Association Headquarters in Johannesburg; to Dr. F. Keen of the Johannesburg Non-European Hospital; and to Drs. I. ## 'Private' Blood Factors, Homozygosis, and the Search for New Blood Groups

Levine[1], in a review of the newer blood factors, classed several of them as 'private'. These, he said, "are characterized by the positive or negative reactions being limited to members of a particular family". He cited as 'private' five antibodies reported by various investigators. J. J. van Loghem and van der Hart[2] have since reported a sixth.

How 'private' a blood factor appears to be may depend upon the population studied with the antibody defining the factor. For example, a year or so ago, we received blood from an American Indian woman who, in her ninth pregnancy, gave birth to a baby who died of erythroblastosis. Her blood contained an antibody which agglutinated the blood of her husband and of some, though not all, of her seven living children, but did not agglutinate the blood of 794 other American Indians. Using the antibody on this population only, the factor it defined fell into the class of a 'private' blood factor; but when the antibody was tested with the blood of whites it was readily shown to be anti-*Kell*. The husband was found to be heterozygous *Kk*. On inquiry it was found that his mother was white. From this observation, we suggest that one should inquire into the racial origin of the stimulator of an antibody defining a 'private' blood factor, and if he be found to be of different race from the person who has developed the antibody, members of his race should be tested.

Sometimes, when questioning does not suggest that a person carrying a particular blood group antigen has a foreign ancestor, a hint may be obtained by detailed blood grouping. When we found anti-*D* in the blood of an *Rh*-negative woman, we genotyped the family. The husband was $R_1R_z$ and the three children $R_zr$. $R_z$ is rare in whites but common in American Indians. When we questioned the woman, she said that her husband's mother was born in Scotland, his father in Canada in a district where many Scots settled 140 years ago. She thought of him as a Scottish Canadian, or, as we would say, Caucasoid. But we know that originally the marriage of a white man to an Indian woman was the rule rather than the exception in the area where the husband's father was born. We have little doubt that his $R_z$ came from an Indian ancestor. The finding of $R_0$ suggests the possibility of a negro ancestor, perhaps via a Mediterranean ancestor[3]. When no racial difference between stimulator and producer of an antibody is proved or suggested, members of as many racial groups as possible should be tested with the antibody, before the factor it defines is set down as 'private'. These 'private' antibodies may be of great ethnological value.

Other observations on American Indians led us to give some thought to homozygosis. In a study of the blood groups of the Blood and Blackfoot tribes of southern Alberta in the summer of 1952, we concluded that pure-bred Indians of these tribes were probably homozygous for the following blood antigens: *k*, $Lu^b$, 'not $Le^a$', *P* and possibly *D*. In such a population, so long as it remains pure-bred, and so long as any member, when transfused, receives blood from his own people only, an immune antibody against a factor for which the population is homozygous cannot be produced. So, for example, the pure-bred Indian cannot produce anti-*k*. On the other hand, the introduction of foreign blood antigens, whether through pregnancy or through transfusion, makes the probability of production of an antibody against one of these antigens greater than in the foreign population. In a random sample of 83 sera of Indian men, women and children, we found a second example of anti-*Kell*, whereas we have identified this antibody only half a dozen times in the examination of sera of some thousands of whites. Further, in such a population, naturally occurring antibodies against a blood factor having a frequency of zero may be present, but cannot be recognized by tests of the population. We have found several examples of anti-$Le^a$ in the sera of Indians, while no Indian blood we have tested has reacted with this antibody. Indian blood, of itself, can give no hint of the *Lewis* system. Many Indian tribes are homozygous for *O*, or, to put it the other way about, have a frequency of zero for *A* and *B*. Their sera, of course, contains anti-*A* and anti-*B*. It comes as something of a shock to think what the history of the *ABO* system would have been had the American Indians been the population of primary investigation: for many tribes there would have been no evidence of its existence; for others the classification could only have been $A+$ and $A-$, for perhaps one tribe in South America $B+$ and $B-$.

Since some Indian populations are homozygous for some blood groups, it seems reasonable to believe that Caucasoid, Negroid, Mongoloid and Australoid populations may be homozygous for other blood groups. This is more likely to be true for populations which have resisted interbreeding or have had, until recently, relatively little opportunity for interbreeding, than it is for those which are highly interbred. In a population exhibiting homozygosis for any blood group, that group must remain unknown so long as tests are carried out only with sera of that population. It is our suggestion that a systematic examination of the sera of persons who have been transfused with the blood of donors of a different race or sub-race, and of the sera of women married to men of a different race or of a mixed race, may bring to light several unrecognized blood-group systems. An experimental programme of inter-racial immunization of volunteers would also be worth while. It need scarcely be said that it will be necessary to test the sera against the blood of persons of the race of the donor, or of the husband. It would be desirable, through exchange of sera between laboratories having access to other racial populations, to test the sera against the blood of several races.

## Adsorption of DDT on Suspended Solids in River Water and its Role in Black-fly Control

Recent investigations on the Saskatchewan River[1] indicate that DDT associated with suspended solids gave outstanding results in the control of black flies. Black-fly larvæ have been practically eliminated from other streams and rivers by the application of DDT at rates as low as 0·1 p.p.m.[2]; but the maximum distance of effectiveness was approximately nine miles and some of the treatments were destructive to other aquatic life as well as black-fly larvæ. In contrast with these results, during 1948–51 larvæ of *Simulium arcticum* Mall. were largely eradicated from sections of the Saskatchewan River for as long as 98 miles by single applications of DDT. The DDT was applied at rates as low as 0·09 p.p.m. for 16 min. as a 10 per cent solution in methylated naphthalene and kerosene.

Outstanding characteristics of the Saskatchewan River include its large rate of discharge (up to 120,000 cusec.), its freedom from aquatic vegetation, and the turbidity of the water during certain seasons of the year. During the tests, the suspended solids content of the water ranged as high as 551 p.p.m., and samples obtained by sedimentation from river water collected so far as 68 miles downstream from the point of application contained 0·24–2·26 μgm. of DDT per gram of solids. This material consisted mainly of clay and fine silt, and laboratory experiments showed that it would adsorb DDT from suspensions of 0·1 p.p.m. of DDT in distilled water.

A study of the feeding habits of the larvæ of *S. arcticum* showed that suspended particles in the river water, including much inorganic material, were consumed. It was also noted during the larvicide tests that the treatments produced much greater mortality of black-fly larvæ than of other aquatic insects, which normally do not feed on small particles suspended in the water. Quantitative samples of aquatic organisms collected before and after single applications of DDT indicated that, whereas black-fly larvæ were almost eliminated for distances ranging from 40 to 98 miles, populations of other aquatic insects were reduced by an average of 50 per cent in two tests and were unchanged in two others.

The results suggest that other fast-flowing rivers in which the water is turbid at the time of treatment might be treated similarly, and perhaps in certain clear-water streams and rivers, finely divided inorganic material with marked DDT adsorptive properties could be added along with the larvicide and kept in suspension.

## Terminology in Bacterial Genetics

THE increasing complexity of bacterial genetics is illustrated by several recent letters in *Nature*[1]. What seems to us a rather chaotic growth in technical vocabulary has followed these experimental developments. This may result not infrequently in prolix and cavil publications, and important investigations may thus become unintelligible to the non-specialist. For example, the terms bacterial 'transformation', 'induction' and 'transduction' have all been used for describing aspects of a single phenomenon, namely, 'sexual recombination' in bacteria[2]. (Even the word 'infection' has found its way into reviews on this subject.) As a solution to this confusing situation, we would like to suggest the use of the term 'interbacterial information' to replace those above. It does not imply necessarily the transfer of material substances, and recognizes the possible future importance of cybernetics at the bacterial level.

## Histochemical Demonstration of Amine Oxidase in Liver

DIANZANI[1] has shown that ditetrazolium can be used for demonstrating the activity of, among other enzymes, tyramine (amine) oxidase in mitochondria isolated from liver and kidney. The essential reaction here is a dehydrogenation[2], and hydrogen acceptors other than oxygen may be used in the oxidation of tyramine by amine oxidase[3]. It is therefore of interest that amine oxidase activity can be demonstrated in frozen sections of the tissue, using a tetrazolium compound as the hydrogen acceptor; even though the method is not entirely satisfactory, it shows the general distribution of the enzyme. Neotetrazolium[4] was found to be much more satisfactory than blue (di-)tetrazolium.

Frozen sections (15–20 μ thick) of guinea pig and rabbit liver were well washed in phosphate buffer for about thirty minutes to remove all endogenous substrates and then incubated with equal parts of 0·1 per cent neo-tetrazolium, 0·1 *M* phosphate buffer of *p*H 7·4 and 0·5 per cent tyramine solution, for 2–4 hr. At the end of the incubation period, the sections were washed in distilled water, fixed in 10 per cent neutral formalin and mounted in dilute glycerol. The use of very thin slices of liver instead of frozen sections for the incubation was found to be advantageous; they can then be fixed in formalin and sectioned on the freezing microtome. Control sections were incubated with (1) octyl alcohol[5] for three hours before incubation with tyramine and (2) potassium cyanide in a final concentration of $3 \times 10^{-3}$ *M*, which inhibits other oxidases but has no inhibitory effect on amine oxidase.

Fat stains red with neo-tetrazolium and, together with the precipitated blue formazan, gives a general purple colour. Large fat globules can be seen in the liver, staining a bright red. This red colour can be eliminated by treating the sections with acetone, which dissolves away the fat, leaving the true (blue) colour of the precipitate. The acetone is removed by washing with water. In many cases the red colour is of advantage as it serves as a counter stain.

For the same period of incubation guinea pig liver showed a more dense precipitate than rabbit liver.

The reaction was not uniform throughout the liver, being more marked in the periphery of the lobule, the centre being comparatively free. The precipitate was always in the cytoplasm of the cell; the nucleus did not show any reaction and was unstained. Octyl alcohol completely inhibited the reaction, no blue colour being visible anywhere in the tissue. Potassium cyanide had no effect on the reaction.

## Lactate-oxidizing Systems in the Mycobacteria

In a recent communication, Y. Yamamura, M. Kusunose and E. Kusunose[1] described two "lactic oxidases" prepared from *Mycobacterium avium*. "Lactic oxidase I" is said to be a new type of lactate-oxidizing system which catalyses the reaction:

$$CH_3.CHOH.COOH + O_2 \rightarrow CH_3.COOH + CO_2 + H_2O. \quad (1)$$

The authors are apparently unaware that a soluble aerobic dehydrogenase catalysing the same oxidation of L-lactate was extracted from *Mycobacterium phlei* several years ago[2]. Preparations of a similar, if not identical, enzyme have been obtained from *Mycobacterium smegmatis* and *Mycobacterium tuberculosis* var. *hominis* (*H*37 strain)[3]. For these and other reasons, it was suggested that L-lactic acid oxidase is an enzyme common to all species of acid-fast bacteria[4].

One of the hypotheses originally put forward to explain reaction (1) postulated three consecutive steps[2]:

$$CH_3.CHOH.COOH + F = FH_2 + CH_3.CO.COOH \quad (2)$$

$$FH_2 + O_2 = F + H_2O_2 \quad (3)$$

$$CH_3.CO.COOH + H_2O_2 = CH_3.COOH + CO_2 + H_2O \text{ (non-enzymic)} \quad (4)$$

Sum of reactions (2) to (4) = reaction (1).

In this scheme, *F* was assumed to be an autoxidizable flavoprotein containing flavin-adenine-dinucleotide because this class of protein was found in the enzyme preparations; but it was pointed out that the hypothesis could not be tested satisfactorily until purer preparations became available[2,4]. Yamamura *et al.* have likewise assumed that "lactic oxidase I" is a flavoprotein with flavin-adenine-dinucleotide as its prosthetic group.

Our assumption identifying the lactic enzyme with a flavoprotein has proved to be false. Using large quantities of bacteria, one of us (F. B. C.) has achieved a considerable purification of the L-lactate-oxidizing enzymes extractable from *Mycobact. phlei*, *Mycobact. smegmatis* and *Mycobact. stercoris*. These preparations exhibit identical enzymic behaviour. Flavins (free and combined) are removed during the purification, details of which will be published elsewhere. The most active preparation from *Mycobact. smegmatis* has $Q_{O_2}$ (per mgm. nitrogen) = 166,000 at the optimum *p*H (5·2) and at 38°. This is sixty times as active as the best preparation of Yamamura *et al.*

Concentrated solutions of partially purified enzyme are orange-yellow in colour and exhibit three electrophoretic components, one of which contains the enzyme. The pigment migrates with the enzyme. The absorption spectrum shows typical protein bands in the ultra-violet region with additional absorption at 380–403 mμ due to the pigment. It is possible that the pigment is a prosthetic group of the enzyme, but this is unlikely since the pigment is removed progressively as the enzyme is purified.

*Mechanism of reaction.* Yamamura *et al.* consider that their experiments exclude the possibility of formation of hydrogen peroxide. The evidence seems to be that oxygen consumption and carbon dioxide production in reaction (1) are unaffected by addition of catalase or catalase plus ethanol. This evidence shows (*a*) that catalase does not inhibit the oxidation of lactate, and (*b*) that coupled oxidation does not occur in the presence of ethanol and catalase (carbon dioxide production unaltered). Though significant, this evidence is not conclusive. If pyruvate and hydrogen peroxide react spontaneously on the enzyme surface where they originate, there may be limited diffusion of hydrogen peroxide to an indicator system.

Our purified enzyme preparations behave in a similar way with catalase. Nevertheless, the experiment illustrated in the accompanying table supports the view that hydrogen peroxide is formed in accordance with reactions (2) and (3). The experiment employs horseradish peroxidase and *p*-aminobenzoic acid as a means of detecting hydrogen peroxide[5]. In the presence of peroxidase, *p*-aminobenzoic acid is oxidized only when lactate is oxidized simultaneously; in the absence of peroxidase there is no coupling.

Detection of Hydrogen Peroxide during the Oxidation of Lactate

| Additions | Oxygen uptake (μl./60 min.) | Dye formation |
|---|---|---|
| Nil | 0 | Nil |
| *p*-Aminobenzoic acid + peroxidase | 0 | Nil |
| Lactate | 381 | Nil |
| Lactate + *p*-aminobenzoic acid | 394 | Nil |
| Lactate + peroxidase | 345 | Nil |
| Lactate + *p*-aminobenzoic acid + peroxidase | 384 | Red |
| Pyruvate + *p*-aminobenzoic acid + peroxidase | 0 | Nil |

Warburg manometric cups contained: 0·2 ml. enzyme solution (L-lactic acid oxidase from *Mycobact. smegmatis*) and 0·9 ml. 0·2 *M* acetate buffer, *p*H 5·2. Gas, air. Temp., 38. Inseal, 0·2 ml. 2 *N* sodium hydroxide. Additions: 1·0 *M* DL-lactate (0·5 ml.); 0·2 *M* pyruvate (0·5 ml.), peroxidase solution (0·2 ml.); 0·025 *M* *p*-aminobenzoic acid (0·2 ml.); water to make total volume, 2 ml. in each case.

We have not encountered a DPN-linked anaerobic dehydrogenase like "lactic oxidase II" in the organisms we have studied.

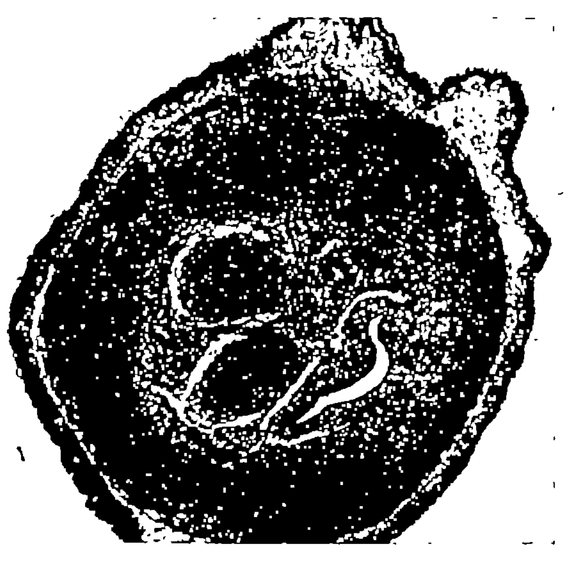
## A Sphincter in the Umbilical Ring of the Rabbit

During the course of some experiments on fœtal rabbits, a very marked constriction was observed in the umbilical cord at the umbilical ring; the abrupt narrowing in this region accompanied the closure of the length of the umbilical vessels in response to traction or to cooling of the cord. A circular band of smooth muscle in the umbilical ring region has been described for the horse[1] but for no other animal, and Sir Joseph Barcroft suggested that the structure of the rabbit's umbilical cord should be studied in more detail.

Serial sections of the umbilical vessels, in the full-term fœtal rabbit, showed that there is a thin layer of unstriped muscle fibres surrounding their adventitia; this was recognizable around the branches of both the arteries and the vein a few millimetres from where they emerge from the placenta. When the three large umbilical vessels lie side by side in the umbilical cord proper, the outer portions of this muscle layer fuse and the muscle fibres can be seen circularly arranged under the amniotic sheath; the inner portions of the muscle layer between the three umbilical vessels gradually disappear. The circular fibres increase in number and the sphincter attains its maximal thickness 2–3 mm. in front of the abdominal wall; it continues thus for 2–3 mm. inside the abdomen, and gradually tapers to its connexion with the abdominal muscle. Ranson impregnation, together with control positive material, revealed no nervous supply to the sphincter. It was already present in the cord of 20-day rabbit fœtuses. No similar structure was found in the rat, in the human or in the guinea pig umbilical ring.

It is doubtful whether this sphincter has any physiological function *in utero*, since it is not innervated and responds most readily to local stimulation. At birth it is obviously an efficient mechanism for ensuring closure of the three umbilical vessels, for in the region of the sphincter there is more complete reduction in the size of the lumen of the three vessels than is found on either the fœtal or placental side of the umbilical ring. It is difficult to understand its special relationship to the mechanism of birth in the rabbit. However, effective closure of umbilical vessels may be a function of their length as well as the relative contractile properties of the vessel walls. The latter is impossible to assess from histological specimens; but it is noteworthy that the umbilical cord proper in the rabbit is comparatively short, and the sphincter may have been developed as an extra safeguard.



Transverse section of umbilical ring of the rabbit showing unstriped muscle sphincter surrounding umbilical vessels

This work was begun in the Department of Physiology, Bedford College for Women, London. My thanks are due to Miss Beryl Shilton, who prepared many of the slides. Miss Helen Perry, of the Department of Zoology, Birkbeck College, London, is carrying out an exhaustive study of the umbilical rings in other animals.

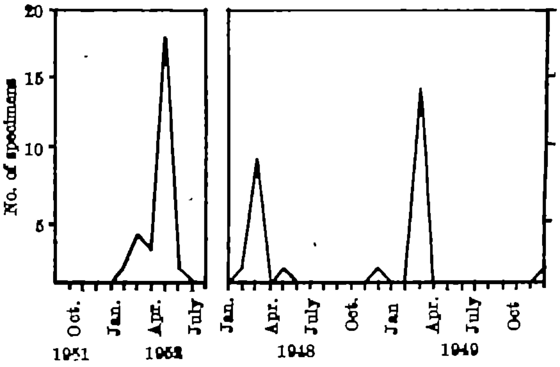
## Catches of *Coryphæna hippurus* (L.) in the Western Indian Ocean

While carrying out a survey of the pelagic fishes of East African waters, twenty-seven specimens (twenty-four female, three male) of the dorade or dolphin fish were caught during multiple trolling operations during September 1951–August 1952. All the dorade were taken close inshore, and from the graph it can be seen that the catches were limited to the months February–June. Although the total catch is not large, it must be remembered that the dorade is of widespread distribution in tropical seas and is nowhere abundant. In all specimens the state of maturity of the gonads was determined.

Reference to unpublished data of the Mauritius–Seychelles Fisheries Survey, 1948–49 (Wheeler and Ommanney), provides evidence of the capture of twenty-seven dorades (seventeen female, ten male). With one exception, they were taken on or near the many shallow-water banks of this area. No ripe females were noted; but ripening females occurred in March in both years. In East African waters ripening females occurred from March to May, and ripe females in May.

These observations suggest that *Coryphæna* makes an inshore spawning migration between February and June in the western Indian Ocean. Confirmation



Catches of *Coryphæna hippurus* (L.)

or otherwise of the movement indicated should be obtained during the future work of the survey.

## A Biological Agent for securing Large Numbers of *Amœba proteus*

The role of *Oscillatoria* for purifying freshwater reservoirs is well known. For some years now, I have been applying successfully this biological agent to 'cleaning up' amœba cultures. Ordinary laboratory cultures, unless rigidly controlled, tend to become choked with algæ in the course of time. It is a tiresome manipulation to separate out the amœbæ in sufficient numbers when it is desirable to make a quantity of stained preparations, or to secure the large numbers of young amœbæ which are required when a study of mitosis is being made. If, however, among the algal contents one introduces *Oscillatoria*, the filaments of this grow over and bind together the wheat grains and the algal contents into a cylindrical mass. The rest of the vesicle is quite free from weed; but young amœbæ, some rotifers and small flagellates creep out on to it and multiply, and so a white carpet is formed consisting mainly of amœbæ quite free from debris. These can then be pipetted off into the fixative, or used for a study of mitosis.

If now a new receptacle with water and wheat be prepared, the cylindrical mass can be removed bodily, placed into the prepared receptacle and squeezed, when a new culture results, which will be ready for use in about three months.

## Laws of Addition and Substitution in Atomic Reactions of Halogens

Quantitative developments of the observations communicated some time ago[1] on the reaction of N-chlorosuccinimide with toluene has led to a clarification of the reaction mechanism.

Let us, however, consider first the reactions between an organic substance ($R$H) and a halogen ($X_2$) in homogeneous gaseous systems or in non-polar solutions. If the reaction proceeds by atoms and free radicals, the following reactions (substitution *s*, addition *a*) must be expected:

$$X_2+M \rightarrow 2\,X+M \qquad (1)$$

$$X+\mathrm{H}R \rightarrow \mathrm{H}X+R \quad (2s) \qquad X+R\mathrm{H} \rightarrow XR\mathrm{H} \quad (2a)$$

$$R+X_2 \rightarrow RX+X \quad (3s) \qquad XR\mathrm{H}+X_2 \rightarrow XR\mathrm{H}X+X \quad (3a)$$

$$R+\mathrm{H}X \rightarrow R\mathrm{H}+X \quad (4s) \qquad XR\mathrm{H} \rightarrow R\mathrm{H}+X \quad (4a)$$

$$X+XR \rightarrow X_2+R \quad (5s) \qquad X+XR\mathrm{H}X \rightarrow X_2+XR\mathrm{H} \quad (5a)$$

$$2X+M \rightarrow X_2+M \qquad (6)$$

$$X+R \rightarrow XR \quad (7s) \qquad X+XR\mathrm{H} \rightarrow XR\mathrm{H}X \ (\text{or } X_2+R\mathrm{H}) \quad (7a)$$

$$R+R \rightarrow R_2 \quad (8s) \qquad XR\mathrm{H}+XR\mathrm{H} \rightarrow XR\mathrm{H}R\mathrm{H}X \ (\text{or } XR\mathrm{H}X+R\mathrm{H}) \quad (8a)$$

By applying the usual stationary state method, the rate laws in $(X_2)^{1/2}$, $(X_2)$ or $(X_2)^{3/2}$, which were found empirically by Bodenstein, Kistiakowsky, Schumacher, Van Artsdalen and others[2], are obtained. But it can be shown, in agreement with all previous observations, which of these rate laws must be expected in any specific case, by estimating the rate constants, that is, activation energies and partition functions for the eight different elementary steps. A quite satisfactory 'first approximation' is obtained in the following way: it is assumed that activation energies exceed endothermicities by 2 to 5 k.cal.; electronic and vibrational partition functions are assumed to be equal for all particles, and rotational partition functions are calculated neglecting structural particularities.

Further, the rules governing the competition of addition and substitution may be calculated; the ratio of addition to substitution being:

$$r(a/s) = k_{2a}/k_{2s}(1 + k_{4a}/k_{3a}\,(X_2)\,),$$

or for low concentrations of $(X_2)$—the order of magnitude of which can be estimated satisfactorily:

$$r(a/s) = k_{2a}k_{3a}\,(X_2)/k_{2s}k_{4a}.$$

Thus addition is favoured by high, substitution by low, values of $(X_2)$; this explains the 'perturbations' of addition reactions observed, for example, by Schumacher[3].

It has been shown that in the reaction of N-chlorosuccinimide with toluene, traces of impurities (for example, $10^{-6}$ water) lead, in the course of an induction period[4], to formation of H$X$, which yields with N-chlorosuccinimide halogen molecules ($X_2$); the latter give by thermal dissociation the primary halogen atoms. These could now react according to (2*s*) or (2*a*). In the first case, the following reaction chain would be started:

$$X + \mathrm{H}R \rightarrow X\mathrm{H} + R \qquad (a)$$

$$\mathrm{SN}X + X\mathrm{H} \rightarrow \mathrm{SNH} + X_2 \qquad (b)$$

$$R + X_2 \rightarrow RX + X \qquad (c)$$

It can easily be understood that (2*a*) cannot be followed by a rapid reaction: (i) actually the above substitution–addition rule means that (3*a*) is slow as compared to (4*a*) so long as ($X_2$) is low; (ii) the alternative reaction, $\mathrm{SN}X+XR\mathrm{H} \rightarrow \mathrm{SN}+XR\mathrm{H}X$, is only possible if the dissociation energy of the SN—$X$ bond is smaller than or equal to an $X$—$X$ bond; we have several indirect arguments for the contrary. (This reaction is certainly negligible compared with 3*a* because of its high (negative) entropy of activation.)

Thus the reactions (*a*), (*b*) and (*c*) are the only alternative. They explain all the observed facts[4], and we believe that they can be applied also in the case of other reagents giving atomic halogenations. It is not necessary to admit *ad hoc* a 'specificity' of the SN radical, as has been done previously[5].

Actually it appears, for the first time quantitatively, that the high specificity of reagents is due to the concentration at which reagents are maintained in a system, much more than to the inherent specificity of these reagents. We believe that this may have general importance in biological reactions. In fact, more than twenty years ago, one of us (P. G.) was able to discuss this possibility many times with the late Profs. F. Haber and R. Willstätter, when they first suggested the role of atomic and free radical reactions in enzymatic processes[6]; we did not succeed then, however, in putting forward an adequate quantitative model[7].

Two of us (J. A. and P. A. G.) wish to express our thanks to the Institute of Applied Scientific Research (I.R.S.I.A.), Brussels, for fellowships, which have enabled us to carry out this investigation.

## Dissociative Chemisorption of Carbon Dioxide on Solid Catalysts

THE chemisorbed state or the degree of dissociation of a polyatomic molecule on the surface of a solid catalyst may be important for understanding the catalysed reaction. We know little, however, for example, of the state of carbon dioxide, ethylene and other molecules, or even of such a simple diatomic molecule as carbon monoxide; in the latter case, contradictory views as to whether its chemisorbed state on a metallic surface is molecular or atomic have been put forward.

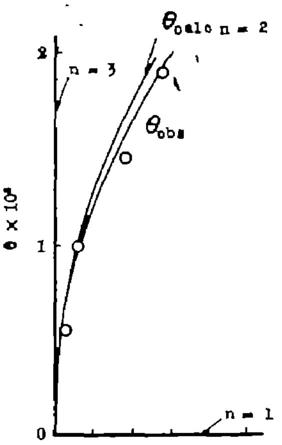
Kwan and Fujita[1] have recently investigated the chemisorption of carbon dioxide on reduced nickel at 200° C. with particular reference to its chemisorbed state, using statistical mechanical considerations, and we conclude that it is completely dissociated into three statistically independent atoms. This statement was borne out by the following fact. Using the heat of chemisorption of carbon dioxide derived from the isotherm for a sparsely covered surface, the fraction of surface covered, θ, was calculated from the expression:

$$\theta^n = \frac{P}{P_0}\exp \Delta\varepsilon/RT, \qquad (1)$$

where $n$ is 1 when the substrate molecule is undissociated at the surface and 2 or 3 respectively for the case when dissociated into two or three parts, $\Delta\varepsilon$ is the heat of chemisorption, $P$ the equilibrium pressure and $P_0$ a constant, being expressed for the present case as:

$$P_0 \doteq kT\,\frac{(2\pi mkT)^{3/2}}{h^3}\,\frac{4\pi^2 IkT}{h^2}\prod^{i}\{1-(\exp-h\nu_i/kT)\}^{-1}\exp 7/2.$$

The fraction covered was also derived from the amount of carbon dioxide chemisorbed and the Brunauer–Emmett–Teller surface area[2] of the adsorbent, assuming that each metal atom at the surface is equally capable of chemisorbing a dissociated particle. This was compared with the coverage given by equation (1) for three different chemisorbed states respectively. It was found that much better agreement between them can be attained when completely dissociative chemisorption, that is, $n = 3$, is assumed.



Chemisorption isotherm of carbon dioxide on copper ferrite at 300° C.

The method of investigation has now been applied to chemisorption on oxide catalysts of spinel type. Copper ferrite, copper chromite and zinc chromite, respectively, were prepared by the usual precipitation from the stoichiometric mixture of the corresponding salt, and dried and ignited in vacuum at 500° C. The 1 : 1 stoichiometric proportion of MeO—Me$_2$O$_3$ was confirmed in each case by chemical analysis and also the spinel structure by X-ray analysis.

The chemisorption isotherm of carbon dioxide was determined at temperatures ranging from 100° to 300° C. and at pressures from $10^{-3}$ to 1 mm. mercury by the same method as that described in a previous paper[3]. The isothermal heat was found to be 31, 21 and 16 ± 0·5 k.cal./mole, respectively, for copper ferrite, copper chromite and zinc chromite. The plot of the coverage against equilibrium pressure, for example, in the case of copper ferrite when $n = 1$,

$\theta_{\text{obs.}}$ AND $\theta_{\text{calc.}}$ FOR CHEMISORPTION OF CARBON DIOXIDE

| Oxide | Wt. (gm.) | Surface area ($M^2$) | $T$ (° C.) | $P$* (mm. mercury) | $\Delta\varepsilon$ (k.cal./mole$^{-1}$) | No. of chemisorbed CO$_2$ molecules per cm.$^{-2}$ | Fraction of surface covered | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | $\theta_{\text{obs.}}$ | $\theta_{\text{calc.}}$ $n = 2$ | $n = 1$ | $n = 3$ |
| CuFe$_2$O$_4$ | 4·2 | 210 | 300 | 0·01 | 31 | $1·3 \times 10^{12}$ | $2·6 \times 10^{-3}$ | $2·8 \times 10^{-3}$ | $7·6 \times 10^{-6}$ | $1·9 \times 10^{-2}$ |
| CuCr$_2$O$_4$ | 1·0 | 43 | 200 | 0·01 | 21 | $2·3 \times 10^{11}$ | $4·6 \times 10^{-4}$ | $4·9 \times 10^{-4}$ | $2·4 \times 10^{-7}$ | $6·2 \times 10^{-3}$ |
| ZnCr$_2$O$_4$ | 3·5 | 103 | 100 | 0·01 | 16 | $4·5 \times 10^{11}$ | $4·0 \times 10^{-4}$ | $4·1 \times 10^{-4}$ | $1·7 \times 10^{-7}$ | $5·5 \times 10^{-3}$ |

* $P$ was taken arbitrarily within the range of the observed chemisorption isotherm.

2 and 3, respectively (denoted by '$\theta_{\text{calc.}}$'), is shown in the accompanying graph. This shows that only when $n = 2$ does $\theta_{\text{calc.}}$ fit closely the experimental value (denoted by '$\theta_{\text{obs.}}$'), which was obtained by assuming that $5 \times 10^{14}$ metal ions or the average numbers of metal ions per square centimetre of the adsorbent surface are equally capable of chemisorbing each dissociated particle. The result is obviously in contrast to that for nickel quoted above. A similar result was also obtained in the case of copper chromite and zinc chromite, as shown in the accompanying table.

As can be seen from the table, if we assume that $n = 1$ or 3, the fraction covered, or $\theta_{\text{calc.}}$, fails to account entirely for the experimental value ($\theta_{\text{obs.}}$) for any of the oxide catalysts, whereas $\theta_{\text{calc.}}$ corresponding to $n = 2$ gives a good fit. Quite apart from the numerical agreement between $\theta_{\text{calc.}}$ and $\theta_{\text{obs.}}$ in the latter case, it seems very likely that the carbon dioxide molecule is chemisorbed with partial dissociation into two particles, that is, presumably into chemisorbed carbon monoxide and oxygen atoms.

Detailed accounts of this work will be published in *J. Res. Inst. Catalysis, Hokk. Univ.* Our thanks are due to Prof. J. Horiuti for his advice.

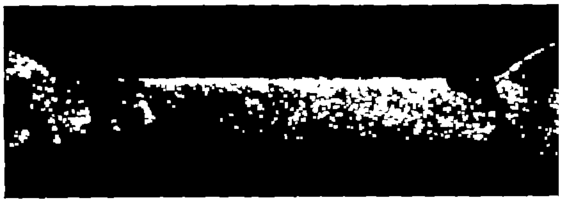
## Preparation of Single Crystals of Titanium and their Mode of Deformation

SINGLE crystals up to 20 mm. × 2·5 mm. × 1 mm. have been prepared in pure titanium by a modified strain anneal technique. Pure titanium of hardness of 90 V.P.N., indicating 0·01 wt. per cent of oxygen plus nitrogen[1], prepared in this laboratory by the van Arkel process, was first arc-melted[2] and then cold-rolled with intermediate annealing at 860° C. to strip in which there was very little preferred texture. By suitably gettering the purified argon used as a protective atmosphere throughout this preparation, the hardness of the titanium was not increased. The grain-size of this strip was fairly coarse and uneven (1–25 grains/mm.$^2$). Tensile strains from 0·05 to 5 per cent did not give large crystals on annealing for 90 hr. at 860° C.; but compressive strains between 0·1 and 1 per cent, followed by similar annealing, produced in one-third of the specimens a crystal occupying the whole cross-section and an appreciable part of the gauge length, as illustrated.

In a less pure titanium (V.P.N. 165, 0·1 wt. per cent oxygen plus nitrogen[1]) the strip had an even grain-size of 20–25 grains/mm.$^2$. Compressive strains produced no appreciable grain growth on the annealing; but a tensile strain of 1¼–2¼ per cent resulted in single crystals.

It is suggested that the purity of the titanium influences the techniques required to produce single crystals because it affects the initial grain size of the strip. It is known that initial grain size is a critical factor in the technique of strain anneal growth[3].



Single crystal of titanium, etched in 8 per cent nitric acid, 8 per cent hydrofluoric acid in water. × about 4

The size required in titanium (25 grains/mm.$^2$) coarse in comparison with the size required in Arm iron (120 grains/mm.$^2$) and is thought to be necessa to reduce deformation twinning during the critic straining. In a specimen with an initial grain si of 100 grains/mm.$^2$ the critical straining induced considerable amount of deformation twinning, an subsequent annealing produced no enhanced grai growth, but the deformation twins did disappear.

During tensile tests in a rigid machine at roo temperature it has been shown that, when suitabl oriented, single crystals of pure titanium slip o (0001) [11$\bar{2}$0] as well as on (10$\bar{1}$0) [11$\bar{2}$0] and (10$\bar{1}$ [11$\bar{2}$0]. Rosi, Dube and Alexander[4] only observe slip on (10$\bar{1}$0) [11$\bar{2}$0] and (10$\bar{1}$1) [11$\bar{2}$0] in work wit coarse polycrystalline titanium made by the Kro process. Slip on (0001) [11$\bar{2}$0] has been shown to b required if the rolling textures in titanium are to b completely accounted for[5]. The critical resolved she stress for slip on the basal plane appears to be high than that for slip on (10$\bar{1}$1), which is in turn high than that for slip on (10$\bar{1}$0). Deformation twinni on (10$\bar{1}$2) and (11$\bar{2}$1) has been observed. Deformatio or kink bands are formed both during basal a (10$\bar{1}$0) slip, and the bend plane has been identifie as the (11$\bar{2}$0) plane at right angles to the operati slip direction. The bent region of the lattice at t boundary of the band exhibits asterism, while t slipped region outside and inside the band does n On annealing, the bent region polyganizes as show by the break up of the asterism into discrete spo and the appearance of boundaries at right angl to the slip lines on the micro structure.

The stress–strain curve at room temperature sho a drop in load required to maintain plastic fl reminiscent of the yield phenomena in iron, b which appears to coincide with the appearance the deformation band.

A more complete survey of these results is in t course of preparation for publication.

I wish to thank Dr. G. A. Geach, leader of t Physical Metallurgy Section of this laboratory, f encouragement and helpful discussion; I also wi to express my thanks to Dr. T. E. Allibone for p mission to publish this paper.

# FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

## Monday, April 20

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Annual General Meeting; Dr. J. R. Boer: "Organo-Mercurial Fungicides".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Laboratory Experiments on Protective Gear" (to be opened by Mr. H. P. Young).

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Sebastian Snow: "Amazon Adventure".

## Tuesday, April 21

British Psychological Society, Industrial Section (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Dr. Peter F. C. Castle: "The National Institute of Industrial Psychology Foremanship Research, 1948–1953".

Society of Chemical Industry, Agriculture Group (in the Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. H. L. Penman: "Estimating the Water Requirements of Plants".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Mr. H. S. Gibson: "Two Oilfields in Northern Iraq" (Presidential Address).

## Wednesday, April 22

Institute of Petroleum (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Symposium on "The Engine Testing of Lubricating Oils".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. H. M. Barlow and Mr. A. E. Karbowiak: "An Investigation of the Characteristics of Cylindrical Surface Waves"; Prof. H. M. Barlow and Dr. A. L. Cullen: "Surface Waves".

Society of Chemical Industry, Nutrition Panel of the Food Group (in the Chemical Society's Rooms, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Dr. W. F. J. Cuthbertson: "Synthetic Food Possibilities"; Mr. P. N. Williams: "Synthetic Fats". Summary of Series by Dr. Norman Wright (Food and the Future, 4).

## Wednesday, April 22—Saturday, April 25

Institute of Metal Finishing (at the Hotel Majestic, Harrogate).—Spring Conference.

## Thursday, April 23

Institution of Chemical Engineers (at the May Fair Hotel, Berkeley Street, London, W.1), at 11 a.m.—Thirty-first Annual Corporate Meeting; at 12 noon.—Mr. Stanley Robson: "Changes in Roasting Practice and Furnace Design" (Presidential Address).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Geoffrey Taylor, F.R.S.: "Experimental Study of Standing Waves"; Mr. T. V. Davies: "Forced Flow of a Rotating Viscous Liquid which is Heated from Below".

Linnean Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. S. M. Manton, F.R.S.: "The Structures, Habits and Evolution of Millipedes".

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Sir Alexander Carr-Saunders: "Colonial Universities To-day" (Holland Memorial Lecture).

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. P. I. Dee, F.R.S.: "The Dilemma of Lord Kelvin" (Forty-fourth Kelvin Lecture).

## Friday, April 24

Society of Chemical Industry, Oils and Fats Group (at the Low Temperature Research Station, Downing Street, Cambridge), at 10.30 a.m.—Symposium on "Oxidation" (Speakers: Prof. C. E. H. Bawn, F.R.S., Dr. C. H. Lea, Dr. A. Banks, Dr. L. A. O'Neill and Dr. J. H. Skellon).*

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. A. T. Bowden, Mr. P. Draper and Mr. H. Rowling: "The Problem of Fuel Oil Ash Deposition in Open-Cycle Gas Turbines".

Television Society (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Fleming Memorial Lecture.

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Rockets" (Chairman: Prof. A. D. Baxter; Speakers: Dr. A. C. Merrington, Mr. L. Lubbock and Prof. A. D. Baxter).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. Archibald G. B. Russell: "Tradition and the Coronation".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Statistician (with a university honours degree in science, mathematics or economics, and some experience of research involving the analysis and interpretation of mass data) in the Central Statistical Office of the Town Clerk's Department—The Town Clerk, Room 30B, Council House, Birmingham 1 (April 25).

Entomologist (male, interest in ecology and mechanical ability important) for work in Insecticides Department primarily in connexion with field experiments—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 25).

Mechanical Engineer or Physicist (with first- or second-class honours degree or equivalent in mechanical engineering or physics) at the Royal Aircraft Establishment, Farnborough, to undertake experimental and theoretical work with light mechanisms—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.169/53A (April 25).

Physiologist (with good honours degree in physiology or equivalent qualification, and research experience preferably involving the perfusion of isolated organs) for research on the physiology of lactation—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 53/3 (April 25).

Statistician (part-time, graduate of a British university, with an honours degree, and statistical experience) in the Health and Welfare Department—The Town Clerk, Town House, Aberdeen (April 27).

Readership in Mathematics at Westfield College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 28).

University Demonstrator in Animal Nutrition—The Secretary, School of Agriculture, Downing Street, Cambridge (April 28)

University Lecturer in Agricultural Botany—The Secretary, School of Agriculture, Downing Street, Cambridge (April 28).

Assistants (2) in Mathematics, and an Assistant in Statistics—The Secretary, The University, Aberdeen (April 30).

Readership in Chemical Pathology at the Royal Veterinary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Readership in Public Health at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 1).

Temporary Lecturer (with special reference to horticulture) in the Department of Botany—The Registrar, The University, Manchester 13 (May 1).

Chair of Applied Mathematics—The Registrar, University College, Singleton Park, Swansea (May 2).

Physicist or Engineer (with first- or second-class honours degree or equivalent in physics or engineering) in the Instrument and Photographic Department of Royal Aircraft Establishment, Farnborough, for research and development work in connexion with gyroscopic equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.88/53A (May 2).

Readership in Geography, and an Assistant Lecturer in Zoology—The Registrar, Trinity College, Dublin (May 10).

Lecturer in Civil Engineering—The Secretary, Queen's University, Belfast (May 15).

Assistant (male, with a degree in horticulture, agriculture, or botany, together with a keen interest in the scientific aspects of practical fruit culture and ability to convey the results of research to scientists, advisory officers and growers) in the Scientific Liaison Section—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (May 16).

Organic Chemist (Senior Research Officer grade)—The Director, Laboratory of Human Nutrition, Oxford (May 16).

Senior Lecturer or Lecturer in Coal Mining Engineering at the New South Wales University of Technology—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (May 25).

Assistant Lecturer in Archæology—The Registrar, University College, Cathays Park, Cardiff (May 30).

Senior Lecturer in Physiology—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (June 20).

Assistant Lecturer (with honours degree in physics, preferably with a special interest in illumination or optics) in the Department of Applied Physics—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

Assistant Lecturer and a Demonstrator in Organic Chemistry—The Registrar, The University, Nottingham.

Biochemist (with a first- or second-class honours degree in chemistry, and research experience preferably in the field of protein chemistry) in the Endocrine Unit—The Secretary, London Hospital Medical College, Turner Street, London, E.1.

Chemist to assist in laboratory dealing with members' day-to-day production problems—The Printing, Packaging and Allied Trades Research Association, Randalls Road, Leatherhead, Surrey, quoting CH.

Chown Research Professorship in Chemistry—The Principal, Queen's University, Kingston, Ont., Canada.

Engineers or Physicists for Royal Aircraft Establishment, Farnborough: Scientific Officer-Engineer (preferably aeronautical) or Physicist, for research on flutter and vibration problems in aircraft structures (Ref. A.81/53A), and a Senior S.O.-Electrical or Electronic Engineer, for development and application of electrical and electronic equipment in connexion with above research (Ref. D.121/53A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Physicist as Head of the Physics Department—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

RESEARCH STUDENT IN THE CANCER RESEARCH DEPARTMENT, to work on problems concerning the mechanism of enzyme synthesis—The Secretary, London Hospital Medical College, Turner Street, London, E.1.

SCIENTIFIC OFFICERS (with first- or second-class honours degree, or equivalent, in physics or engineering) for operational research on a wide variety of problems, in London and provinces, under direction of Scientific Adviser to the Air Ministry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.285/52A.

SCIENTIFIC OFFICERS, Grade I and Grade II (with a good honours degree in engineering or mathematics; some research experience in either mechanical or civil engineering is essential for Grade I) IN THE RESEARCH DEPARTMENT (Engineering Division) at Derby—The Director of Research, Railway Executive, 222 Marylebone Road, London, N.W.1.

SENIOR RESEARCH WORKER, and a RESEARCH ASSISTANT, to undertake a fundamental study of the viscosity of liquid metals—The Registrar, The University, Edmund Street, Birmingham 3.

# GOVERNMENT SCIENTIFIC RESEARCH IN GREAT BRITAIN

During the past year there has been evident in Parliament, from time to time, a desire for fuller information regarding the work of the Department of Scientific and Industrial Research. While strong support was forthcoming in a debate in the House of Commons last June for the Advisory Council's plea, in its last year's report, for more continuity in the financial support of the Department's work, members of Parliament are manifestly and rightly concerned to satisfy themselves that the considerable sums concerned, approaching £6 millions in the estimates for 1953–54, are expended wisely and without waste. There has been little criticism of the general basis of the Department's plans to meet post-war needs, though some concern has been expressed at the delay in giving full effect to those plans; and, according to the Department's report for 1950–51, this was even then causing grave anxiety to the Advisory Council.

The report of the Department for the year 1951–52, which has now been published (see p. 716 of this issue), while making a praiseworthy effort to provide the detailed information which Parliament is seeking, is marked by the same note. "Nothing," writes the Advisory Council, "has since occurred to mitigate our anxiety. In fact, we find ourselves reviewing the relation between our scientific needs and our scientific resources with steadily deepening concern." The difficulty of drawing a balance between advisory and *ad hoc* work on one hand, and longer range research on the other, is recognized; but while agreeing with those who, like Sir Henry Tizard, stress the utmost importance of widely disseminating and using to the full existing information, the Advisory Council points to evidence that deficiencies in knowledge have often to be made good before fully satisfactory answers can be found to some of the problems and inquiries put to the Department. These deficiencies will become more serious as industry becomes more conscious of the help to be gained from science, unless the reservoir of scientific knowledge from which answers are derived is enlarged by further research.

"We and our colleagues on the Advisory Boards," continues the Advisory Council, "are already deeply concerned at the inadequacy of the effort the D.S.I.R. Establishments can devote to the longer range research. Basic research is hardly worth doing if the effort that can be devoted to it is insufficient to secure steady progress, and the suggestions made from time to time to reduce the present meagre effort appear to us to be ill-founded. We remain firmly of the view that there is no alternative to the planned expansion of the D.S.I.R. that our predecessors recommended six years ago."

In spite of this comment, however, the Advisory Council gives little or no information as to the present position of what are described in its previous report as the most urgent items in the Department's building programme. After a delay of twelve months due to the standstill on civil building work, work was begun on the second new laboratory building for mechanical engineering research in May 1952, but construction of the Heat Transfer and Creep Laboratories has still not begun. While the expenditure in this field increased from £137,566 in 1950–51 to £267,434 in 1951–52, much work has still to be carried out at the National Physical Laboratory, or at the universities under contract—and this when the industries which the new laboratory will serve are responsible in the aggregate for exports to the value of £750 millions a year and play the most important part in rearmament.

While such slender progress is being made in discharging the Department's obligation to develop the new Mechanical Engineering Research Laboratory as the chief national centre for basic research in all branches of mechanical engineering, progress in the development of the Hydraulics Research Station at Wallingford has been equally slow. The damage done to the coastal defences of Britain by the high tides and gales early this year points to the danger of neglect in this field and the probable cost to the nation of delay. The work of Lord Waverley's committee would probably be greatly assisted had this Station already been fully in operation. Apart from this, as noted in last year's report, important contracts have been lost to Britain through the absence of a centre with facilities for basic research and experiments with models on coast erosion and accretion, the effect of dredging and drainage schemes on estuaries and rivers, and the design of dock and harbour works so as to avoid silting. Experimental work in Britain is still in its preliminary stages, and relies on the National Physical Laboratory and the Imperial College of Science and Technology. Nor does the report indicate whether or not there has been further delay in letting the contract for the erection of the new Water Pollution Research Station at Stevenage or acquiring a site for a new Road Research Laboratory. Design work on the project for the new tank and water-tunnel which was stopped in October 1951 has, however, been resumed; but it appears that, since the project is still "subject to review in the light of the current economic situation", the importance of an up-to-date 'tank' and ancillary equipment for studying the design of ships' hulls is not fully appreciated, although Britain still constructs one-third of the world's shipping.

Some attention is given in the present report to the remaining two matters in the building programme which were stressed last year as specially urgent—the Radio Research Station and the Building Research Station. The hope is expressed that the construction of the permanent buildings on the site at Slough, referred to in the previous report, will be commenced in 1953, but meanwhile the work has to continue partly in huts and partly at the National Physical Laboratory. Apart from a small amount of fundamental research in progress at two universities, with support from the Department of Scientific and Industrial Research, the Radio Research Station is the only establishment in Great Britain doing fundamental work in this field.

The Radio Research Station was one of the three establishments specially visited by the Advisory Council during the past year, and it was noted that at present about half the staff of the organization is engaged in work on propagation and about one-third on research on properties of materials used in radio construction. The Council was impressed by the unanimous opinion which it encountered that, while increased facilities are urgently needed, so that more effort can be directed to problems of importance to the manufacturing side of the industry, this effort should not be obtained by curtailing research on propagation. It was also regarded as essential, in the present stage of the development of radio forecasting, that those engaged in it and in organizing ionospheric observations should continue to work in close conjunction with those carrying out research on propagation. Nevertheless, the Summary of Expenditure appended to the report shows that expenditure on radio research was reduced by some 20 per cent during 1951–52.

We refer later to two features of the Department's work which are well illustrated by the position of the Radio Research Station, and pass to the work of the Building Research Station. The Advisory Council was also impressed by the work of this Station and its practical value to the building and contracting industries. It stresses particularly the investigation of the causes of defects in buildings; the work on thermal and acoustical insulation of buildings and on heating systems; and the work on alternative methods of construction, which has saved the industry much wasted effort. The Station has evolved a cheaper and better mortar, now in general use, and has shown how substantial economy in cement can be achieved in concrete and in external rendering. Current work on the causes of heavy maintenance costs of buildings and on eliminating unnecessary handling of materials during construction is also noted, and an experimental study of the planning of dwellings conducted in co-operation with housewives has led to modifications in the planning and equipping of kitchens which should result in economy in cost and increased satisfaction to the housewife.

It appears that the industry is taking more notice of the results of this work, which are being applied more widely. The Advisory Council is satisfied that, to meet the increasing needs of the industry and to economize in man-power, it is essential that the various branches of the work of the Station should be brought together on a single site with as little delay as possible. The report gives, however, no indication as to the progress made in the reconstruction and extension of the Building Research Station, of which the previous report had stated: "far more remains to be done, including the acquisition of additional land".

In view of this, it is surprising to find in the report of the Committee of the Privy Council that the resources available for building research are to be curtailed. There may be some substance in the view that the staff employed in building research in October 1951 represented an excessive proportion of the restricted total staff available for the Department, and the Committee of the Privy Council points out that when the reduction has been made the non-industrial staff for building research is more than one-seventh of the total for all the Department's research establishments and more than one-and-a-half times as large as that of any other establishment except the National Physical Laboratory. In the estimates for 1953–54, the actual reduction in staff is given as 39 on the 1952–53 figure of 577, and the expenditure as £366,790, compared with £378,904 for 1952–53. Even more surprising is the contrast between this decision and the firmness with which the Government holds to its programme of building three hundred thousand houses a year.

Even if the belief that at the present time this housing programme represents too large a proportion of the country's economic resources is unfounded, it is scarcely consistent with the Government's programme of eliminating waste to hold up investigations into how to build houses more efficiently and cheaply. Doubts as to the wisdom of the economies which the Committee of the Privy Council or the Advisory Council proposes are further suggested by the reference in the latter's report to the Geological Survey. The Survey furnishes reliable advice to industry and to government departments on such matters as mineral deposits, water supplies and the planning of mining operations, and in connexion with the execution of many civil engineering projects. Such advice is usually based on the geological map, on which the geologist records the results of his work; present-day demands for geological information require the compilation of such maps on a scale of six inches to the mile for most areas of Great Britain. When the Department of Scientific and Industrial Research prepared its post-war plans, it was estimated that some 33,000 square miles of Great Britain had not been surveyed on this scale, and the plan of expansion for the Geological Survey then approved provided for the completion of the mapping programme in about thirty years. At the present rate of progress it will take more than one hundred years to complete, and the Advisory Council's plea for additional staff for field-work, and its reference to the delay in dealing with inquiries caused by this slow progress, should be viewed also against the disparity between the expenditure on the Geological Survey and that, for example, on the corresponding surveys of the U.S.S.R. or the U.S.A. Nor would the increase in the estimated expenditure on the Survey to £176,706 in the 1953–54 Estimates, compared with £164,817, appear likely either to increase appreciably the rate of progress or diminish that disparity; expenditure in the United States before the Second World War was already £1 million compared with £70,000 in Great Britain.

Apart from expenditure on building research and on the National Physical Laboratory (reduced from £721,855 in 1952–53 to £666,785 in 1953–54), the 1953–54 estimates for the Department of Scientific and Industrial Research show slight increases over the estimates for 1952–53; only for radio research is there a significant increase—from £14,903 to £74,649, with an increase of 87 in the staff, to a total of 112. The impression derived from the estimates in the light of this report is of trifling and indecision, and a failure to grapple with the real issues. The resources of the Department appear to be spread too thinly over too wide a range of activities, and the Advisory Council appears to be reluctant to take the ruthless action which would really bring home to the nation and to the government the price which may be paid for niggardliness where research is concerned.

But it is not merely that proposals, such as the Committee of the Privy Council makes, for cancelling authorized vacancies in staff, are as likely to cause waste as economy: there is to be sensed something of a rift in outlook between the Committee of the Privy Council and the Advisory Council. It is hard to reconcile the former's decision, though reluctant, "that some contribution must be made by the Department in the general economies that are being made in the government service as a whole", with the "steadily deepening concern" of the Advisory Council. Nor does the effect of this decision "not to eliminate any major plan or activity, but to slow down some work and to arrest, for the time being, most of the planned expansions of activities" easily harmonize with the Advisory Council's firm view that "there is no alternative to the planned expansion of the Department of Scientific and Industrial Research that our predecessors recommended six years ago". Elsewhere, in concluding its report, the Advisory Council adds: "We are, however, becoming more and more convinced that science will never be adequately used in this country until many more scientists and technologists are employed throughout industry, not omitting the direction and management". Ostensibly the words are directed at industry and call for wider provision for higher technological education; but the Advisory Council could equally be aiming them higher.

That passage, however, concludes a discussion on technical information services and the measures being taken by the Advisory Council to stimulate the utilization of existing knowledge by industry. Reference is made here to the survey of technological resources and the requirements of industrial firms in the north-west of Britain now being conducted by the Manchester Joint Research Council; but the summary of expenditure this year does not disclose the expenditure on intelligence. With the Committee of the Privy Council's decision to seek its main economies, after building research, in the headquarters office, the omission may or may not be significant. The estimates for 1953–54 show a reduction of £14,292 in headquarters expenditure; but whether or not that has curtailed the activities of the intelligence division, the possibility of some degree of overlapping may merit examination; thus there is no clear justification in the report for the grant of £15,000 during the past three years to the Association of Special Libraries and Information Bureaux.

To suggest that major and minor activities of the Department should be rigorously scrutinized and ruthlessly pruned where their continuance on the existing scale cannot be justified in the national interest is not to advocate the reductions in the present effort which the Advisory Council regards as ill-founded. It may be the only way to overcome the obstacles hindering the development of the Department's plans to which the Advisory Council refers, for unless the resources at the disposal of the Department are very considerably expanded, only concentration of effort on carefully selected fields and objectives, and the elimination of some major activities, will permit the effective pursuit of the selected objectives and avoid increasing frustration, waste of effort and fruitless dissipation of resources. The Advisory Council appears to be aware of this danger, but it has failed so far to give such a lead, and the Committee of the Privy Council rejects the policy.

The dangers of the present situation are not confined to the Department. The Department has now an established and recognized place in the organization of research in Great Britain, and whatever criticism may from time to time have been made of the scale of its operations and the appropriateness of some of its research projects, there has been no suggestion that its activities should be seriously curtailed. Little has, in fact, been heard of late regarding the appropriateness of the research associations as a means for prosecuting industrial research compared with the research organization within industry. Indeed, it now seems to be accepted, even by those who lean to the adoption of the sponsored research institution of the Mellon Institute type as supplement or alternative, that they have a marked field of their own, not only in operational research but also in the dissemination of information and in technological training.

The general value of the Department's work is well attested by the present report alone; but so also is the extent to which its work is interlocked with the rest of the research effort of Great Britain and, to some extent, its provision for higher education. Proposals for expansion or curtailment or reorganization of the Department cannot be considered in isolation; this is well illustrated by the Department's relations with the universities. The Department makes very considerable grants over periods of years to the universities for special investigations. It also spends some £250,000 on grants to students and senior research awards at the universities; but it appears from the present report that the Department to some extent relies upon the universities to carry out investigations under contract which its existing establishments are unable to pursue. This is notable in radio research, for example, in hydraulics and in mechanical engineering, and in the present situation there would appear to be a distinct danger that the policy may be pushed too far. Sir John Stopford recently expressed concern that the large increase in the external public responsibilities of the universities since the Second World War might deflect university staffs from their primary duty of teaching and research. Sir John thought that the universities should reject the heavy responsibility of research enterprises too big for the limited resources of a university.

Others besides Sir John Stopford have expressed concern at the possible effect of sponsored research on university work; and the implications of this trend should be given more attention by the Advisory Council than appears from this present report. Allied to this question is that of the proper balance to be struck between fundamental research and *ad hoc* short-term investigations. That is never an easy decision, particularly when some of the *ad hoc* investigations and the testing work strengthen the contact between the Department's staff and industry. Nevertheless, it would appear from the Advisory Council's comments on radio research and some other activities that there is danger of testing work absorbing an undue proportion of the effort of some establishments. The possibility of transferring such testing work to a separate bureau or organization with no responsibilities for research appears to merit examination. If it could be effected, such a transfer would remove one factor which encourages an exaggerated view of the extent of the Department's true research effort.

That, and the relation of the Department's work to the general research effort of Great Britain and also to the universities, are matters to which the Lord President of the Council and his Committee should be addressing themselves with vision as well as urgency. On the disposition of the Department's own resources, the Advisory Council could do something more than reiterate its predecessor's recommendations for planned expansion. A more detailed and forceful exposition of the value of the Department's work to the nation seems also to be required.

Clearly, the Advisory Council cannot immediately survey the activities of all its establishments in the way that it has examined those of three of the research associations. It should not be impossible, however, to cover with reasonable speed and thoroughness in some such way those features of its work which in last year's report were singled out for special mention as in urgent need of expansion. If the case for such expansion were thus presented to the Lord President of the Council and to Parliament, backed by the Advisory Council to the extent of resignation or to the re-allocation of the present resources to other purposes where they could be more effectively used, it is hard to believe that the position would not be reconsidered by the government.

Last year's report raised the crucial issue of reasonable year-to-year financial flexibility for the Department, and the present report fully emphasizes its importance. That issue is, however, now completely over-shadowed by the fundamental one of the whole future of the Department. Whether its activities are to be expanded, reorganized or considerably curtailed can only be wisely determined in the light of a national policy for science and technology. It is to be hoped that the Advisory Council's present call for help will be noted by the Parliamentary and Scientific Committee and other bodies able to influence the government. The present unsatisfactory situation should be ended, and the future activities of the Department reviewed in the light of a policy taking full account of the nation's resources in materials and man-power. Only in the light of such a review and policy can wise decisions be made which will enable the Department to concentrate its resources on the approved objectives, in the confidence that those resources are adequate to the task, and that it can offer the conditions of service which will attract —and retain—scientists and technologists of the high calibre required.

# PREHISTORIC AMERICA AND POLYNESIA

## American Indians in the Pacific

The Theory behind the Kon-Tiki Expedition. By Thor Heyerdahl. Pp. xv+821+90 plates. (London: George Allen and Unwin, Ltd.; Stockholm: Bokförlaget Forum A.-B.; Oslo: Gyldendal Norsk Forlag, 1952.) 70*s.* net.

THOR HEYERDAHL is an enthusiast. His epic 'Kon-Tiki' raft-voyage across the eastern Pacific, enduring privation and risking death, was undertaken to support a theory. His latest book, massive and lavishly illustrated, presents the evidence for that theory, whole-heartedly, persuasively, and often uncritically.

The theory is ingenious. It is, briefly, that the evidence for the generally held idea of the Asiatic origin of the Polynesian people and Polynesian culture is quite inadequate, and that two streams from the American continent have been responsible. The first, Heyerdahl argues, went raft-borne from the Peruvian coast in pre-Inca times, approximately about A.D. 500. These were the people who provided the "Caucasian-like elements" of strongly-bearded, light-skinned, fair-haired folk mentioned in Polynesian tradition and by some early European voyagers. They were responsible, he holds, for introducing cotton, sweet potato, gourd and many other plants to Polynesia, and for many cultural items, notably the sculpture of huge anthropomorphic statues in stone, of which the best-known examples are on Easter Island. But, it is pointed out, the present-day Polynesians do not make much use of rafts—they are adept in the manufacture and use of canoes. Moreover, before Europeans came, they were ignorant of the loom, of pottery, of cereal cultivation and of other features characteristic of Central and South American cultures. Hence, Heyerdahl postulates a second stream of immigrants, a Kwakiutl-type of people arriving from Queen Charlotte Sound, British Columbia, where these items were lacking, about the beginning of the present millennium. It is these so-called "Maori-Polynesians" who are held to be responsible for the large canoe-hulls of Polynesia, and for many other cultural features, including adzes, rectangular plank houses, massive timber-carving, short striking-clubs, fire-walking and cannibalism.

The author builds up a case for Amerindian relationships and stimulus in Polynesia that is far stronger than any advanced hitherto. Among his most telling points are: the favouring effects of the major eastward movement of prevailing winds and currents; the sailing possibilities of the Peruvian balsa raft; the (so far) admitted American origin of the sweet potato and of the 'native' Polynesian cotton with its twenty-six haploid chromosomes; the lack of the *B* blood-group among Polynesians as against its prevalence in South-East Asia; and the striking superficial similarities and suggestive distribution of certain types of Polynesian and Amerindian sculpture. But much of what the author treats as proof will appear to many anthropologists, even to those with no axe of origins of their own to grind, as only surmise of more or less plausibility.

One difficulty is that much of the argument rests on seizing quite general similarities as significant of some kind of connexion. The division of the Indian society of the north-west Pacific coast into three separate social classes—aristocracy, commoners, slaves—is said to be "followed closely" by the Maori, the Society islanders and some other Polynesian groups, who "strictly adhered to the same division" (p. 141). As regards land tenure, it is stated that "the state was completely communistic among both the northwest Indians and the Maori-Polynesian tribes" (*ibid.*). This amateurish kind of expression is valueless in investigating relationships; it ignores basic elements in structure and organization. Moreover, comparisons which show differences are apt to be neglected. The Polynesians are stated to have had a system of patriarchal clan units, with marked analogy among the Kwakiutl, who "reckon descent usually in the father's sept, and *marry into some other*" (my ital., p. 141). Even granted the propriety of the "patriarchal clan" notion, which the complexities in both societies render dubious, it should be pointed out that on Heyerdahl's own quotation from Goddard, as well as according to data from Boas, the Kwakiutl are primarily exogamous, whereas the Polynesians are not.

Again, far too much reliance is placed on genealogies, myth and tradition in tracing connexions. Recent work in anthropology has shown that such memory material is to be interpreted primarily as a clue to contemporary social relationships; its value as a historical record is very limited. This caution is especially necessary if one attempts to use translations of Polynesian proper names. The many homophones to be found in Polynesian—and it does not appear that the author speaks any Polynesian dialect well—make it highly conjectural to assign a meaning to such a name unless one knows the circumstances in which the name was bestowed. The author translates, for example, *Tu-te-rangi-marama* as "Marama, the Sacred of the Heaven" (p. 722); *Mata-ki-te-rangi* as "Eyes Facing Paradise" (p. 756); and *Vaka-akau-uli* as "Steersman-of-log-craft" (p. 726). When we know that these could be also translated much more prosaically as "Tu of the bright sky", "Face to the sky", and "Canoe of dark wood", they lose their alleged importance as migration indicators. The various sun-god equations of the Polynesian Tangaroa with the Peruvian Kon, and of Tiki or Maui-tikitiki with Ticci are far-fetched. And to state that a connexion between a stone talisman, *mauri*, and the ocean-voyaging culture-hero Maui "cannot be proved, but is etymologically very possible" (p. 245), because early Polynesian voyagers are said to have taken such talismans with them in their canoes, is too casual.

In his anxiety to leave no loose ends, the author brushes negatives aside. The Polynesians had no pre-European cereals. Yet maize was a characteristic food-plant in the Peruvian area from which the author supposes them to have come. How did it escape them? By having been lost during the landing of the Amerindian craft through the surf on Polynesian reefs, or by having failed to give a successful crop after having been sown, he answers. But the question does not really interest him. The absence of pottery from Polynesia, too, attracts discussion only to demonstrate the lack of relation with South-East Asia, whereas no very cogent reasons are given to explain why pottery should not have been brought from Peru, where it had reached a high state of development by the time that the ancestors of the Polynesians are said to have left.

Finally, the author rather overdoes his argument about the virtual impossibility of the ancient Polynesians making headway against the trade winds and the prevailing currents—the "one-way ocean escalator from Peru westwards". Elsdon Best and S. Percy Smith have pointed out three factors which are relevant for voyages in the opposite direction. First, the prevailing winds do not prevail always. Winds, often of considerable strength, blow for significant periods from west-north-west or north-west or even south-west. Secondly, Polynesian canoes could beat to some extent against a contrary wind, helped by the long steering-oar. Thirdly, in a contrary wind that was not too strong the Polynesian often paddled his craft. Moreover, the effects of the equatorial counter-current, variable and weak as it often is, are not to be dismissed. Without decrying the author's magnificent achievement on his raft, it may be fairly said to have involved seamanship rather than sailing skill, and one receives the impression that he consistently undervalues what an oceanic sailing canoe can do.

Despite its huge amount of material, the book is ably written, with a lively style, and the argument is cleverly presented. Provided the reader is prepared for an all-out statement rather than the dispassionate examination of the case, he will be interested and even entertained. But also he should remember that the problems discussed are not those which most anthropologists regard as most important in the Pacific to-day.

RAYMOND FIRTH

# SCIENTIFIC THOUGHT OF THE EARLY NINETEENTH CENTURY

## Genesis and Geology

A Study in the Relations of Scientific Thought, Natural Theology and Social Opinion in Great Britain, 1790–1850. By Charles Coulston Gillispie. (Harvard Historical Studies published from the income of the Henry Warren Torrey Fund, Vol. 58.) Pp. xv+315. (Cambridge, Mass.: Harvard University Press, 1951.) 30*s*. net.

THE author of the book under notice is not a geologist, or even a scientist, but is assistant professor of history at Harvard. "Genesis and Geology" is rather a forbidding title, reminiscent of a type of book published in considerable numbers and widely read during the first half of the nineteenth century. It recalls, for example, the Rev. John Pye Smith's "Relations between the Holy Scriptures and Some Parts of Geological Science", published in 1839, which attained five editions. In fact, Prof. Gillispie's book is an interesting, well-written, scholarly and at times even amusing study of the relations between scientific thought, natural theology and social opinion in Britain between the years 1790 and 1850.

Its publication arose out of the author's special interest, as a historian, in the nineteenth century, and his belief that issues stemming from the growth and dissemination of science may be approached by the historian as problems of intellectual history. Such studies he regards as desirable for the understanding of science as well as history. Because so much has been written about the period following the publication of Darwin's "Origin of Species", Prof. Gillispie concluded it would be more profitable to examine the preceding half-century, a period when the relation of science to religious beliefs was very much a matter of public concern. As a result, inevitably, he found himself forced to study the development of geology, rather than biology, for that was the golden age of geology. It was then the most popular science with the British public, with many followers on the Continent, and in the United States, too. Moreover, the period covered encompassed the publication of two outstanding geological classics, Hutton's "Theory of the Earth" (1795) and Lyell's "Principles of Geology" (1830–33). At about this time, however, some well-known geologists issued works the titles of which showed that they still had no difficulty in reconciling the new geology with the Mosaic account of Creation. A well-known example is Dean Buckland's "Reliquiæ Diluvianæ, or observations on the organic remains in caves . . ., and on other geological Phenomena attesting the action of the Universal Deluge" (1823). In addition, numerous works by naturalists with little or no claim to eminence appeared, with the definite object of reconciling the latest geological views with religious beliefs. An example is the book by the Rev. John Pye Smith, to which reference has been made above. Finally, the publication of Robert Cambers's "Vestiges of Creation" (1844) and Hugh Miller's counterblast, "Footsteps of the Creator" (1847), formed a link with the Darwinian period.

The excitement caused by the publication of the "Origin of Species" was not new in kind. Earlier discoveries, particularly in geology, had seriously challenged not only the literal interpretation of the Book of Genesis, but also the traditional and widely held belief that Providence controls the order of Nature to fulfil a divine purpose. The "Origin" added fuel to a fire already burning.

Here, then, is a book to be read especially by all who wish to appreciate the scientific and social background of the half-century or so preceding the publication of Darwin's "Origin of Species". It is carefully documented and includes, as well as upwards of six hundred text references, a bibliographical essay. It should also be consulted by geologists interested in the history of their subject, more especially because very many of the sources noted will not be found in standard histories of the subject.

# IMPACT OF MAN ON BRITISH WILD LIFE

## The Changing Wild Life of Britain

By H. L. Edlin. Pp. viii+184+36 plates. (London: B. T. Batsford, Ltd., 1952.) 21*s*. net.

THE wild life of Britain has been subjected to constant changes from the earliest times through the influence of man, who has introduced new plants and animals, driven others away, and altered the environment of those that have survived his interference. The dominating factor in the life of any wild animal in Britain to-day is its relations to man; "running parallel with the social, agricultural and industrial revolution of our human society, there has been a gradual change in the wild life of the country-side, which is still far from ended. Every change in methods of husbandry, sporting customs, or even the ownership of land, has aided certain organisms and upset others". This book deals with some of the more obvious changes that have taken place in the British flora and vertebrate fauna.

About two-thirds of the book is devoted to the fauna, mainly the mammals and birds, and the rest to the flora. Four chapters are given to mammals: the deer, the carnivores, the rodents, and the semi-domesticated cattle, sheep, goats and ponies that have free range over some of the moors and mountains in Britain—the last a chapter of much interest. The probable origin of these animals, and of some of the domestic breeds, is discussed, and the enormous influence that sheep-grazing has had on the character of the British flora and fauna is emphasized. "The implications to the naturalist are obvious—he will seek in vain for 'natural' vegetation over most of the British Isles; what he will find will be sheep induced, or at least sheep influenced, vegetation."

The section on birds points out that, although several species have been unable to withstand changed conditions and are no longer British breeding birds, only one, the great auk, has become extinct. On the other hand, many introduced species, especially among the waterfowl, have now become naturalized and are established members of the fauna.

The story of the flora is one of continual enrichment; only a few rarities have been lost, but scores of ornamental plants, weeds, and even forest trees have been introduced deliberately or by accident. The account of the introduced trees is particularly well done, as would be expected from the author's professional connexion with forestry.

The book admirably succeeds in its purpose of giving a survey of the endless changes wrought by man upon his surroundings. It is full of information presented in an attractive form; it is well written, and illustrated with many good photographs. The text is also embellished with numerous figures, but many of the reproductions of Bewick's wood engravings have, unfortunately, been enlarged and printed on paper too coarse to do justice to the delicacy of the originals. The more open woodcuts taken from "Matthiolus" to illustrate the plants are much more successful.

In a book of this nature that covers so wide a field in such detail there are bound to be some points on which a carping critic might check the author. But they are minor matters; the book can be warmly recommended to all naturalists.

L. HARRISON MATTHEWS

# CONFORMAL REPRESENTATION

## Conformal Mapping

By Prof. Zeev Nehari. (International Series in Pure and Applied Mathematics.) Pp. viii+396. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 64*s*.

## Conformal Representation

By C. Carathéodory. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 28.) Second edition. Pp. ix+115. (Cambridge: At the University Press, 1952.) 12*s*. 6*d*. net.

CONFORMAL representation is a many-sided subject, of interest to geographers, physicists, mathematicians and engineers. It started with problems of mapping, but developed into the theory of functions of a complex variable. Valuable contributions were made by Riemann, who stated the fundamental theorem that any simply connected domain can be conformably mapped on a circle. His proof was based on Dirichlet's Principle and used intuition to infer the existence of a function with certain properties. Another proof is based on boundary-value problems and the Green's function. Modern writers prefer a third method, using only the theory of functions. It is a great merit of Prof. Z. Nehari that in his book, "Conformal Mapping", he has combined an account of modern methods with a return to the spirit of Riemann, and has written for the physicist and engineer as well as for the mathematician. To make the book self-contained except for a knowledge of calculus, the first four chapters give an account of harmonic functions, analytic functions, the complex integral calculus, and families of analytical functions. The chapters are stated (not quite convincingly) to be suitable for those with no previous knowledge of these subjects. The preliminary informal discussion of Montel's normal families in Chapter 4, showing why the investigation is necessary, is admirable. These introductory chapters occupy about one-third of the book. Chapter 5 starts with the mapping properties of analytical functions, the 'linear' (or bilinear) transformation, and Schwarz's lemma, and then proves the fundamental theorem. Chapter 6 gives the mapping of certain special functions, including elliptic and elliptic modular functions. Chapter 7 deals with the conformal mapping of multiply-connected domains, including a careful treatment of the Green's function and Dirichlet's Principle, of which a preliminary account was given in Chapter 1. The book concludes with an index, but no bibliography or references to original papers. There are many problems and exercises in each chapter.

A few points for criticism can be made. The statement (p. 32) that the results in the previous sections concerning harmonic functions "are true regardless of whether the domains in question are simply-connected or multiply-connected" is open to doubt. The conditions for which Cauchy's integral theorem are applied (p. 183) do not seem to be included in those for which it is proved (pp. 84–8). The treatment of the Schwarz–Christoffel formula (pp. 189–198) and of the Joukowsky aerofoil profile (p. 271) might be improved by the addition of references from which the reader could obtain further details. However, as a whole, the book is very good.

The first edition of Prof. C. Carathéodory's excellent tract on "Conformal Representation" appeared in 1932. The first three chapters gave a simple account, suitable for beginners, of the 'Möbius' (or bilinear) transformation, non-Euclidean geometry and elementary transformations. The remaining four chapters were much more advanced and dealt with the fundamental theorem and related topics by the most refined modern methods, eliminating all traces of the early approaches and, in particular, of the physical ideas by which Riemann was so much influenced. To a beginner such a treatment may appear artificial, but the advanced student can realize its merits.

The present second edition, of which the manuscript was completed by the author before his death in 1950, contains an excellent extra chapter on the general theory of uniformization, which uses the method of van der Waerden to prove the celebrated theorem of Poincaré and Koebe. The bibliography and notes have been rewritten and form a valuable guide to further reading.

H. T. H. PIAGGIO

# DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

## REPORT FOR THE YEAR 1951–52

THE report of the Department of Scientific and Industrial Research for the year 1951–52* includes a brief covering report from the Committee of the Privy Council, over Lord Salisbury's signature, and the thirty-seventh annual report of the Advisory Council, signed by Sir Ian Heilbron, together with the usual summary of work carried out by the various research stations and boards and research associations. The appendixes include a classified list of departmental publications issued during the year, besides lists of assessors to the Advisory Council and of members of the research boards of the Department, of research associations and of grants for special investigations in progress during the year. While the report is an indispensable work of reference on the activities of the Department and is a very readable account of what Britain is getting for the £6 millions provided for these activities in the 1953–54 estimates, with its rising price the report is less than ever a popular account but rather one addressed strictly to the scientific and industrial world.

The gross expenditure of the Department for the year ended March 31, 1952, was £5,452,165, as against £5,007,822 in the previous year; this was reduced by receipts from various sources to £4,956,819, the net increase on 1950–51 being £402,397, and on 1949–50, £1,033,037. The staff of all grades employed in the Department on October 1, 1952, was 4,035 (including 149 part-time), a decrease of 53 compared with the previous year. The largest single item of expenditure was, as usual, the annual grants to research associations, totalling £1,334,863, besides special grants of £52,624. Gross expenditure on the National Physical Laboratory was £840,439, reduced by receipts to £559,335 net. Grants for special researches amounted to £313,693, a decrease of £74,209; and the list of grants for special researches in progress during the year ending September 30, 1952, is of interest in connexion with the recent argument in favour of giving the Department at least the right to carry over unspent money from year to year, if not to extend to the Department the principle of quinquennial grants so as to stabilize its budgetary expectations on a longer-term basis. The majority of the grants listed are spread over a period of years, the largest five being £487,500 to the University of Liverpool for the construction of a 400-MeV. proton synchrocyclotron for nuclear research, £317,700 to the University of Glasgow for the construction of a 300-MeV. electron synchrotron for nuclear research, £231,500 to the University of Birmingham for the construction of a 1,000-MeV. proton synchrotron for nuclear physics research, £191,000 to the University of Oxford for construction of a 140-MeV. proton synchrotron for nuclear physics, and £168,000 to the University of Manchester for radio-astronomy covering from four to six years.

Grants to students amounted to £251,241 net, an increase of £14,529. Net expenditure on mechanical engineering was £267,434, an increase of £129,868; on the Geological Survey and Museum £196,552, an increase of £38,351; on road research £273,259, an increase of £29,277; on the Chemical Research Laboratory £96,523, an increase of £22,346; on hydraulics £53,082, an increase of £27,084; and on fuel research £219,154, an increase of £15,223. Net expenditure of £498,123 on building research, £22,805 on fire research, £185,949 on food investigation, £97,288 on forest products research, £51,632 on pest infestation, and £55,842 on water pollution was of the same order but slightly higher than during 1950–51, while expenditure on radio research was £23,016, a decrease of £6,590. Net expenditure on headquarters administration, etc., was £208,029, and on overseas liaison £66,086, while research contracts again decreased to £34,310 compared with £70,606 during 1950–51. Expenditure on the Provision of Technical Equipment under American Aid increased from £498 to £97,433.

The number of students-in-training was 923, compared with 910 during 1950–51, and, of these, 384 were new. The senior research awards were thirteen in number, of which nine were new, compared with ten in 1950–51, and thirty-eight new grants for special investigations brought the total of such grants to ninety-one, compared with ninety-five in 1950–51. The preponderance in chemistry and physics continued: of senior research awards, five were in chemistry, six in physics and two in engineering; and of the grants for special investigations, twenty-six were in chemistry, forty-one in physics and fourteen in engineering. Of the grants to students, 390 were in chemistry, 276 in physics, 73 in biology, 71 in engineering, 48 in mathematics and astronomy, 38 in geology and mineralogy, and 27 in metallurgy.

The note of anxiety which characterized the report for last year recurs, both in the report of the Committee of the Privy Council and in that of the Advisory Council itself. The reasons for this anxiety and the implications of the measures adopted to meet the financial situation are discussed elsewhere (see p. 709). Apart from this, the most important feature of the former report is the intimation of the decision, in conjunction with the Committee of the Privy Council for Medical Research, and with the subsequent approval of the Lord President of the Council, to appoint two joint committees to study human problems in industry (see *Nature*, April 18, p. 684). The first, the Committee on Individual Efficiency in Industry, will be asked to keep under review the progress of knowledge bearing on the technical efficiency of the individual in industry, advise on general policy in research in this field, direct attention to gaps, make recommendations for filling them, and to consider and report from time to time on the requirements for the training of research workers and technologists in this field. The second, the Committee on Human Relations in Industry, will examine current activities concerning the study of human relations in industry and direct attention to problems of special timeliness and promise on which research might be undertaken or supported by the Department of Scientific and Industrial Research and the Medical Research Council, or other bodies.

The membership of these Committees was announced in the House of Commons on March 24, and the reasons for the decision to appoint the Committees are briefly indicated in a section of the Advisory Council's report. Fundamentally, they arise out of the recognition that the successful introduction of new methods and new equipment depends largely on human factors and that, while the responsibilities of the Medical Research Council and the Department of Scientific and Industrial Research in such matters as affect individual efficiency can be quite clearly defined, a joint approach to the whole field offers real advantage. Human relations are less tangible and more difficult to handle, and both Councils believe that a joint committee, with the first task of reviewing what is being done in this field in Britain and abroad, offers the best means of selecting the most promising lines of work for support by either Council.

---

* Department of Scientific and Industrial Research. Report for the Year 1951–52. (Cmd. 8778.) Pp. 203. (London: H.M. Stationery Office, 1953.) 8*s*. net.

Apart from this, and from the financial situation of the Department, the chief features of the Advisory Council's report are the comments on the increasing interest of the research associations in operational research, on the recommendations of the Cremer report regarding research in chemical engineering, on technical information services, and on the Advisory Council's visits during the year to establishments of the Department. These included the Geological Survey and Museum of Practical Geology at South Kensington, the Building Research Station and the Radio Research Station; and the Advisory Council once again expressed itself as being well satisfied with what it saw and with the manner in which the directors are endeavouring to meet the demands on their restricted resources. In regard to operational research, the report comments on the value of such work in showing where laboratory research can be most profitably directed, and in the experience which it gives the man of science of working with all kinds of people in an industry. The pioneer work of the Cotton Research Association and the Boot and Shoe Research Association in this field is well known, and the Wool Industries Research Association has now made a close study of faults and irregularities in wool cloth, showing in which of the various stages from preparation to finishing they originate. Since the industry, until recently, employed about one mender for every two weavers, this investigation bears on the use of man-power, as well as on quality. An analysis has now been made of the time required for mending each type of fault and the frequency of its occurrence, thus enabling priority in planning research to be given to the investigation of those faults which are economically the most important, and the industry has shown great eagerness to apply the results of these studies in the mills.

An operational research team set up by the Joint Iron Council and the Cast Iron Research Association has visited more than two hundred foundries during the past two years, and the information gained is leading to the wider adoption of sound and economical practices throughout the industry. A statistical survey of children's feet carried out by the Boot and Shoe Research Association has led to the development of a new series of lasts for children's shoes, which, besides greatly increasing the ability of the industry to make children's shoes fit accurately and comfortably, is of importance for the export market. The Iron and Steel Research Association is making a survey to assess the optimum size of ships that can be handled at the principal ports from which iron ore is dispatched to Britain, and is also studying unloading methods to discover the reasons for the rapid discharge of ships at certain foreign ports and the applicability in Britain of the techniques employed.

In regard to the Cremer report, the Advisory Council agrees that the national interest demands a central organization working in collaboration with manufacturers so as to ensure correlation between basic research and actual operation, but the Association of British Chemical Manufacturers and the British Chemical Plant Manufacturers' Association have already arranged to make a more detailed study of information that is available in industrial research establishments and of the resources of these establishments for carrying out further investigations. The survey is expected to take a further six to twelve months and to lead to the establishment of a properly staffed documentation unit. In view of the emphasis laid by the Cremer Committee on improved documentation, arrangements have been made by the Department of Scientific and Industrial Research to prepare bibliographies of selected topics; one on drying has been completed, and another, on crushing and grinding, has been initiated in co-operation with the Institution of Chemical Engineers.

A feature of the summary of work is the increased proportion of space given to the work of the research associations. This is in accordance with the trends of recent reports; it now occupies some 115 pages, as against 72 pages for the work of the research establishments of the Department. The work of the Chemical Research Laboratory and of the National Physical Laboratory has recently been reviewed in these columns, and, from the accounts of the work of the other establishments and the research associations, only a selection can be here made to illustrate the range and extent of the contribution which they make to the national welfare and economy. That of the Joint Fire Research Organization, for example, is preventive rather than of direct value in relation to increased productivity, and is planned mainly in relation to the needs of the various government departments which have responsibilities in connexion with fire protection, and to assist the Fire Offices' Committee and local authorities in framing their requirements. Annual losses from fires usually amount to about £24 millions, approximately half of which is from large fires involving more than £10,000 damage each, and against such figures the significance of the work on smouldering, on the study, with the use of models, of the growth of fire, on the use of water and foam in fire extinction and on dust explosions can be appreciated. Analysis of fire statistics indicates that, while the rate of incidence of fire in television receivers continued to decrease, the hazard is still three times as much as that with radio sets.

Under the Food Investigation Organization, in view of the importance of the problems of storage of home-produced beef, work is being concentrated on improving the quality of frozen meat through the controllable factors prior to slaughter and during storage. Two members of the staff of the Low Temperature Research Station, Cambridge, are working during 1952–53 in the Abattoir Laboratories at Brisbane of the Australian Commonwealth Scientific and Industrial Research Organization and will apply to beef animals on a commercial scale the techniques which have shown promise on the laboratory scale at Cambridge. Preliminary experimental shipments indicate that the better the initial quality of the meat, the less the damage suffered as a result of freezing. Surveys have continued of the wastage and deterioration which occur during the distribution of lettuce, plums, strawberries and Cornish broccoli to the home market, and also experiments on the best storage conditions for certain new varieties of apples and pears. Work on the production of heat by potatoes stored in bulk has permitted general recommendations regarding the height of stacking and the need for ventilation, and progress has been made in identifying some of the many compounds shown by chromatographic methods to be present in apples. Basic investigations have related to the recovery of ascorbic acid from aqueous extracts of lucerne, and a study of the mechanism of action of phenolases on the naturally occurring phenols present in many plant and animal substances has shown that ascorbic acid is a useful inhibitor of enzymatic browning. The demonstration that *iso*citric and malic acids can be oxidized by enzymes isolated from peas by successive transference of hydrogen from *iso*citric and malic acids through coenzyme II to glutathione, thence to ascorbic acid and finally to oxygen, allocates possible functions to the important plant constituents—ascorbic acid and glutathione. Other investigations on the respiration of plant organs promise to illuminate the balance between carbohydrate and acid constituents which accompanies the ripening of fruits, and may lead to control or prediction of the losses of ascorbic acid during storage of plant organs; they have indicated that sterilizing foods with intense beams of high-velocity electrons is a promising process.

Some basic research has been maintained in all sections of the Forest Products Research Laboratory, but much time has been given to the testing of Colonial and other imported timbers, in order to keep pace with the increasing demand for information on their properties and uses. Measurements on adsorption and desorption within the hysteresis loop have been concluded and confirm earlier findings, and work is now in progress on the effect of temperature on the hysteresis loop. A new system of loading has been developed for testing stresses and similar structural units, and research on the physiology of fungi has included the study of the metabolic products of wood-inhabiting fungi. Much time has been devoted to the development of a new technique for observing the collapse of wood during pressure treatment which will facilitate the accurate determination of the relation between temperature and pressure, while work on the treatment of timber in stick, for the prevention of attack by *Lyctus* powder-post beetles, has aimed at finding improved methods of applying DDT and benzene hexachloride to stacks of timber. Fuel research has included investigations on the nature of the processes of maturing of coal, which are believed to change when the coal acquires a minimum density, and on the mode of occurrence of certain minor constituents in coal. The development of a pilot plant for the generation of water-gas from small-sized non-coking coals in a fluidized bed at about 900° C. is proceeding, and in work on the Fischer–Tropsch process it has been found that the activity of an iron catalyst prepared from magnetic iron oxide and alkali is greatly increased by reduction with hydrogen at 300° C. instead of 450° C. and by removing surface alkali by leaching with water. Investigations on the formation and prevention of external deposits on boiler heating surfaces, on the removal of sulphur compounds from flue gas and on the development of combustion chambers to enable solid fuels to be used in industrial gas-turbines has continued, while many new designs of domestic appliance have been tested and much attention given to atmospheric pollution and its prevention.

The development of the new Hydraulics Research Station continued, and considerable progress is reported in building a second wave-basin in the open in which it will be possible to reproduce tidal currents and the rise and fall of the tide at the same time as waves. Tidal studies have concentrated attention on the problem of siltation in the tidal basin at Tilbury, while a report on the approach channel to Heysham harbour has been submitted and an investigation is being carried out on behalf of Lyttleton Harbour Board, New Zealand, into designs for new extensions to the existing harbour. In the field of coast protection a team of five men, led by an experienced hydrographic surveyor, is making a survey on the south coast of England with the object of recording data for comparison with future surveys, so that an accurate estimate can be made of the gain or loss of beach material; and the team will also attempt to find explanations of how these changes occur.

In the Division of Mechanical Engineering, construction of the Hydraulic Machinery Laboratory, though not of the Heat Transfer and Creep Laboratories, has begun, but most of the work on the properties of materials at high temperatures and the work on the metrology of machine tools and screw threads has to be carried out at the National Physical Laboratory. Fundamental work on grease lubrication has recently begun, and a tentative theory of bearing has been developed to take account of the rheological properties of grease. Experiments on fretting corrosion have confirmed the resistance of phosphated steel surfaces: on surfaces so treated it could be virtually eliminated by suitable lubrication. The performance of precision ball-bearings is being studied with special reference to the dimensional accuracy and finish of the ball and track surfaces, and equipment for investigating high-speed gears has been designed and built by a firm of gear manufacturers. The relation between stress and plastic strain in a polycrystalline aggregate has been used to provide a physical basis for the use of the principle of maximum work in macroscopic theory, tests are being made to establish basic principles governing the plastic deformation of metals in press- and drop-forging, and a micro-technique has been developed for measuring tool-wear so that the machining of large quantities of metal is avoided.

The Pest Infestation Laboratory, which works in close collaboration with the Infestation Control Division of the Ministry of Agriculture and Fisheries and with the corresponding division in the Department of Agriculture for Scotland, is becoming increasingly concerned with Colonial problems relating to the storage of foodstuffs, especially of cereals, where the most immediate needs are for the dissemination of existing knowledge and the assessment of problems on which further research is required. Respiration measurements on wheat grain at different humidities at 25° C., in the presence and absence of micro-organisms, indicate a sharp increase in the rate of respiration of normal grain as the moisture content rises above 16 per cent, accompanied by the development of visible external mould, especially at moisture contents of 18 per cent or more. Subepidermal mycelium appears to have no effect on the respiration of damp grain. The protection against infestation afforded by impregnating jute sacking with pyrethrins or piperonyl butoxide, or a mixture of the two, has been investigated, and all treatments with pyrethrin or the mixtures greatly reduced the likelihood of infestation. Tests have also been made on the relative efficiency of vacuum fumigation techniques and straightforward fumigation at atmospheric pressure. Among the problems investigated at the Road Research Laboratory are the effect of striped pedestrian crossings on road casualties, the braking performance of commercial vehicles, the rear lighting of vehicles in relation to accidents, the behaviour of soils in relation to road construction, the possibilities of prestressing concrete for roads, and the improvement of road tar. Further aspects of the treatment of sewage by alternating double filtration are being studied by the Water Pollution Research Organization, as well as the relative importance of factors affecting the toxicity of poisons to fish, while an increasing proportion of the resources of the Laboratory is being devoted to the study of conditions in the Thames Estuary.

New terms of grant were offered to nine research associations for the next five-year period. The British Boot, Shoe and Allied Trades Research Association receives a block grant of £8,000 a year, conditional on £15,000 from the industry, and an additional £100 for each £100 from industry up to a maximum of £10,000. Reference has already been made to the Association's work on children's shoes, but its day-to-day work on shoe-making materials and components is reflected in all categories of footwear. For the British Cotton Industry Research Association, a block grant of £50,000 a year was made, conditional on £220,000 from the industry, and an additional £100 for each £100 from industry up to a maximum of £40,000 for the period April 1, 1954–March 31, 1957. New developments in the textile industry during the year include the registration of Shirley Developments, Ltd., to take over under formal agreements the many commercialized results already in existence. By this means it is hoped to secure that the practical results of research are more quickly, effectively and fully adopted by the industry. Work on the newer fibres is expected to increase, but cotton still occupies the major part of the research programme. The Association's work on sizing warps is estimated to offer savings in starch to the industry of about £200,000 on £1 million, and the radioactive static eliminator, which has been on trial for two years, is now commercially available.

The new block grant for the British Hat and Allied Feltmakers' Research Association for 1952–54 will be £7,000 a year, conditional on £10,000 from the industry, with up to £5,000 on the £100 for £100 basis. The Association reports advances in the knowledge of mercuric carrotting of rabbit fur, which are leading to a better understanding of the process, and an investigation has been started on the effect of different types of dyeing machine on the quality of felt produced. For the two years 1952–53, the British Food Manufacturing Industries Research Association will receive a block grant of £9,000 a year, conditional on £20,000 from industry, with up to a further £6,000 on the customary basis. Besides studies of analytical methods, the keeping qualities of different types of margarine, and the incidence of mould infection, particularly on strawberries and blackberries, the Association is investigating the graining and rheological behaviour of chocolate, which are important in controlling the physical character of the chocolate and in preventing 'bloom'. For the British Non-Ferrous Metals Research Association the block grant for 1954–56 will be £28,000 a year, conditional on £65,000 from industry, with up to a further £15,000 on the usual basis; more than thirty investigations are at present in hand. A novel method of recovering zinc from galvanizer ash has been developed, the general adoption of which would save the galvanizing industry sums covering its entire subscription to the Association for many years. The Association has also developed an anodic test for a naturally occurring inhibitor of the cold-water pitting of copper pipes, which enables the corrosiveness of a water to be assessed in seven days.

A block grant of £10,000 a year has been made to the British Paper and Board Industry Research Association for the period October 1, 1952–September 30, 1957, conditional on £30,000 from the industry, with up to a further £12,000 on the usual basis. Work on effluent problems continued, and as a first step in a long-term study of fibre structure and properties as they affect paper manufacture and, in particular, of the fundamental effects produced by the beating process, a literature survey has been made and new techniques have been developed in preparing fibres for study under the electron microscope. The possibility of incorporating fungicides in the packaging material during manufacture so as to prevent attack of paper and board by bacteria and moulds is being investigated. Besides a block grant of £40,000 a year conditional on £50,000 from the industry, and up to a further £40,000 on the usual basis for the two years 1952–53, the Production Engineering Research Association has been promised £100,000 towards the cost of a new research building at Melton Mowbray, contingent on at least the same amount from the industry. Research in progress has included investigations to enable the accurate calculation of punch loads for a wide range of ferrous and non-ferrous materials, on the performance of experimental aqueous cutting fluids containing various additives and rust inhibitors, and on the effect of tool surface finish on tool life. For the period April 1, 1952–March 31, 1957, the Coil Spring Federation Research Organization will receive a block grant of £5,000 a year, conditional on £6,000 from industry, with up to a further £10,000 on the £100 for £100 basis, and plans have been made for the establishment of a central headquarters in the Midlands; further work on decarburization and its relation to type of steel, spring manufacture and performance has revealed some important features of the manufacture of springs from black rolled bar, and a study on avoiding hydrogen embrittlement has shown that a variety of oxidizing agents, including chromic sulphuric acid, are effective. The Wool Industries Research Association will receive a block grant of £40,000 a year for the period October 1, 1953–September 30, 1956, conditional on £100,000 from industry, with up to a further £30,000 on the usual basis. General recommendations have been made for the use of synthetic detergents in scouring, and work has been started on the effect of chlorination on the dyed strength and shade of nylon, in the presence and absence of wool, while it has been shown that the frictional forces between clean nylon and keratin surfaces are determined by the elastic indentation of the surfaces and the shear strength of the materials.

Other interesting features of the work of the research associations which may be noticed here are the studies on consumer preference carried out by the British Baking Industries Research Association in collaboration with the School of Bakery, Royal Technical College, Glasgow, which have indicated a marked ability to differentiate between shortbreads containing butter and cake margarine, respectively, and between cake products containing margarine with dried egg and butter with fresh eggs, respectively.

There was no evidence that smokers and persons with artificial dentures were appreciably inferior in their ability to taste. The British Electrical and Allied Industries Research Association's preliminary trials of the 100-kW. wind-driven generator in Orkney are being followed by full performance tests prior to permanent commission; preliminary trials of electric weed-killers have given promising results, and work has started on the flash illumination of laying poultry to increase egg production. The British Iron and Steel Research Association's work on graphite electrodes has led to two types of resistivity tests, the adoption of which in some works has offered savings of four to five shillings per ton of steel. The Lace Research Association has developed a new lubricant for lace machines which is as effective as graphite and offers a minor social revolution in the elimination of the saturation of the workers' clothes with graphite which characterized the old conditions. The designs of the Parsons and Marine Engineering Turbine Research and Development Association for turbine machinery in merchant ships have proved so successful overseas that applications are being received for licence agreements from countries outside the United Kingdom, and six licences have been granted. Interest in the use of oonophor oil as a drying oil is rapidly developing, and the Nigerian Government, the Colonial Office and the Paint Research Station are co-operating in exploiting the discovery and establishing a oonophor-growing industry. The Printing, Packaging and Allied Trades Research Association has patented a new design of book-binding which allows a book to open flat without major strain to the back; 'Patracrat', its light-sensitive material for making photo-lithographic plates, has been widely adopted, and much interest has been displayed in its journey shock recorder. The British Rayon Research Association has obtained very promising results with methods it has devised using ultrasonics for the removal of oil stains.

These examples should sufficiently demonstrate how varied is the contribution which the Department of Scientific and Industrial Research is making, alike through its own research stations and organizations and through the industrial research associations, to industrial efficiency and productivity and to almost every side of national welfare. The report shows, too, the extent to which contact and co-operation with industry and with other organizations and government bodies enables the Department to keep in touch with practical needs. Manifestly the wisdom with which the work of the Department is conducted in different fields, and the soundness of the selection of its objectives cannot be judged from an annual report of this order. Confidence in that respect is inspired by the three surveys of the work of the Leather, the Cast Iron and the Ceramics Research Associations which have already been made at the request of the Advisory Council, particularly that of the Leather Research Association. As the Advisory Council points out, however, while such surveys are of considerable value in reviewing progress and assessing priorities, they take time to complete and make considerable demands on the time of all concerned. To conduct such surveys every five years, even for the research associations alone, would be too big a task with existing resources, and the Advisory Council's proposal to arrange for such surveys only when special circumstances indicate the desirability seems reasonable, particularly as it also proposes to require a much more detailed review of the work of each research association before the renewal of grants.

# REFRACTOMETRY OF LIVING CELLS

By Dr. R. BARER *, K. F. A. ROSS † and S. TKACZYK †

Department of Human Anatomy, Oxford

SURPRISINGLY little attention has been devoted in the past to the determination of the refractive index of living protoplasm. Earlier workers who investigated the subject were apparently content simply to record values without interpreting their meaning, and the methods employed were rather crude or subject to considerable error. Vlès[1] pointed out that the refractive index of a spherical or cylindrical cell could be determined by treating it as a lens and measuring its focal length. This method only gave average values for the whole cell, that is, nucleus, cytoplasm and inclusions. Even less-precise methods were sometimes used. Thus, the frequently quoted figures of von Angerer[2] for the refractive indices of bacteria were estimated by comparing the subjective brightness (under the conventional microscope) of bacteria with that of oil emulsions. Other techniques have been reviewed in the literature[3].

## Methods

The method which we have developed[4] originated in a chance observation. During the course of a survey carried out with the phase-contrast microscope on a wide variety of living cells, it was noticed that the cytoplasm of the amœbocytes of earthworm blood appeared bright instead of dark when viewed by positive phase-contrast (and dark when viewed by negative phase-contrast). This was the reverse of the appearance of all other living cells examined in this laboratory, and could only mean that the refractive index of these cells was less than that of the mounting medium. It was then realized that the latter was not physiological saline or serum, as generally employed, but earthworm blood, which contains a considerable amount of dissolved hæmoglobin, so that the refractive index is appreciably raised. When the blood was washed out with saline, the cytoplasm of the same cells became dark, as usual. In order to determine the refractive index of the cytoplasm, it was only necessary to dilute the blood until the cytoplasm virtually disappeared, and then to measure the refractive index of the diluted blood. As it was inconvenient to use blood or hæmoglobin solutions, a search was carried out for other suitable colourless proteins. After several trials, the material now being used as an immersion medium is a plasma albumin preparation which is available as a dried powder. It is soluble in water or dilute saline up to at least 45 per cent w/v, and its salt content and *p*H can be adjusted to suit the particular cells being examined.

This method is, of course, the well-known 'immersion method' of refractometry which has long been used in mineralogy. It has not hitherto been successfully employed in biology because most of the common non-aqueous immersion media damage living cells. Any substance to be used for the refractometry of living cells must fulfil the following requirements: (1) it must be non-toxic and must not affect the structure or function of living cells; (2) it must not penetrate the cell; (3) it must exert a low osmotic pressure, that is, it must be of high

---

† Supported by Medical Research Council Grants.

molecular weight; (4) it must be freely soluble in water so that the refractive index of the solution can equal or exceed that of the part of the cell to be measured. These requirements are met by the albumin preparation actually used. Numerous experiments have shown that motile cells, such as various protozoa, bacteria, spermatozoa and ciliated epithelial cells, remain active and apparently in good condition for at least thirty minutes (and often for several hours) even in highly concentrated solutions. Cell-division and germination of spores have also been observed. The tonicity of the medium has been checked by plotting distribution curves of cell diameter for spherical cells such as spermatocytes. These experiments and full details of the technique will be described elsewhere.

It seems curious that so simple a method could not have been evolved much earlier. On reflexion, however, its success evidently depends on two fairly recent developments. In the first place, moderately pure preparations of suitable proteins have only been available on a large scale within the past few years. True, some early workers attempted to use gelatin as an immersion medium, but as this sets to a jelly in low concentrations, it is of no practical value. The second factor is the development of phase-contrast microscopy by Zernike[5]. This is an extremely sensitive method for observing local variations of refractive index (or strictly, optical path, that is, the product of refractive index and thickness) and thus enables the match between immersion medium and object to be judged with considerable accuracy. Two-beam interference microscopy[6] has also been used in this work, for which it possesses certain advantages over phase-contrast.

## Meaning of Refractive Index: Solid and Water Content of Living Cells

The refractive index of parts of living cells can be measured by this method to an accuracy of the order of 0·001–0·005. Even greater accuracy is possible in some cases, but in general the range of individual variation among cells of one type is greater than the experimental error of a single measurement. The bare figures are, however, of very little interest, and it is only when we consider what they mean that the full significance and possibilities of the method become clear. As a first rough approximation we can regard the living cell as an aqueous solution of protein. If we immerse such a solution in a medium containing the same protein, the refractive index difference between the cell and the medium will vanish when the concentration of protein in the external medium is equal to that inside the cell. Thus, if we were able to use the cell protoplasm as the immersion medium, we could determine its concentration inside the cell. Can we do the same by using a different protein? It is a remarkable fact that equal concentrations of aqueous solutions of different proteins all have approximately the same refractive index. The refractive index varies almost linearly with concentration, and the increase per 1 per cent increase in concentration is known as the specific refractive increment, α. The values of α for nearly all proteins so far studied do not differ by more than about ± 5 per cent from a mean figure of 0·0018. The extreme cases are the lipoproteins, and pigmented proteins such as hæmoglobin, but even here the variation from the mean is only slight. (The figures in the accompanying table were kindly provided by Dr. G. S. Adair.) Thus, if the cell were composed of protein alone, we could determine its concentration by using almost any protein as the immersion medium. Of course, there are other substances present besides proteins. These might be expected to introduce large errors; but, in fact, the refractive increments of nearly all organic substances in solution (and certainly of those likely to be present in living cells) are very nearly the same. Anomalies may occur with pigments (in the region of absorption bands), and with substances containing conjugated double bonds. Materials of special biological interest are the carbohydrates, lipoids and nucleic acid compounds. The first two usually have low values of α, in the region of 0·0014–0·0015. For nucleic acids, α has been variously given as 0·0016[7] and 0·0020[8]. For solutions of tobacco mosaic virus the value is 0·0017[9], that is, about the same as for much simpler proteins. Hence the error in assuming an average value for α for substances present in appreciable amounts in living cells is small, and only in exceptional cases, as perhaps in cells heavily loaded with pigments, glycogen or lipoids, is any considerable error likely to occur. Thus, in brief, the concentration of protein in the external medium, which makes a certain part of a cell vanish, is also the concentration of total solids in that part of the cell. In many cases the proportion of protein is so great relative to other substances that little error is introduced by regarding this figure as a measure of protein concentration. Clearly, if the total solid concentration is $x$ per cent, then the concentration of water is $(100 - x)$ per cent. A simple observation under the microscope thus gives us accurate information about two very important quantities, the estimation of which has always been a matter of difficulty. Measurements of the water content of living cells involving wet and dry weight determinations lack precision because one can never be sure of removing all extraneous surface water. Indeed, any attempt to dry thoroughly the surface of cells or tissues would almost certainly result in changes of cell permeability, perhaps with further loss of water from inside the cell. The great advantage of the new method is that it can be carried out on the living, and as far as can be judged, undamaged cell, and the results apply to individual cells or parts of cells, instead of being average figures based on large numbers of possibly different cells. In other words, the range of variation of water and solid concentration can be estimated in a given type of cell under different physiological conditions.

| Protein | |
|---|---|
| Total serum (human) | 0·00179 |
| Euglobulin | 0·00183 |
| Pseudoglobulin | 0·00181 |
| Total albumin | 0·00181 |
| Recrystallized albumin | 0·00181 |
| Lipoprotein | 0·00170–0·00171 |
| Hæmocyanin *Helix* | 0·00179 |
| *Octopus* | 0·00184 |
| *Carcinus* | 0·00187 |
| Egg albumin | 0·001813 |
| Sheep CO hæmoglobin | 0·001945 |
| Globin (ox) | 0·00178 |
| CO hæmoglobin (ox) | 0·00193–0·00195 |

Specific refractive increments (α) for various proteins (figures provided by Dr. G. S. Adair)

## Applications and Results

It is only possible in the present article to mention briefly a few of the different types of problem which have so far been studied by the technique and to indicate the trend of work now in progress.

(1) *General cytology and biology.* In general, the refractive index of the cytoplasm of most types of living animal cell has been found to lie between

1·350 and 1·367, corresponding to between 10–20 per cent concentration of solids. The degree of variation may be quite small in any given species. For example, the cytoplasm of snail spermatocytes and that of snail amœbocytes each has a refractive index corresponding to about 14 per cent of solids, even though the former are compact spherical cells, whereas the latter are very flat and irregular with extremely thin pseudopodial processes. As is to be expected, there is usually some degree of variation between individual cells of the same type from the same animal. As a rule, however, the extreme values rarely differ by more than ± 10 per cent from the mean value, and often the degree of scatter is very much less. Insufficient work has been done to make any statement about the possible correlation between the age or developmental state of an individual and the solid content of its cells; but such an investigation may provide useful clues to the mechanism of ageing. Even in normal human oral epithelial cells there appears to be a progressive decrease in the water content from the inner layers outwards, probably connected with the degree of cornification. The outermost layers may contain more than 30 per cent of solids, the innermost only about 11 per cent. It would be surprising if changes in the distribution of tissue water did not occur with advancing age.

The study of motile organisms is of particular interest both because of the evidence it provides for the absence of serious damage produced by the immersion technique, and because of the light it may throw on the mechanism of locomotion. Many species of protozoa have been observed, and special attention has been paid to some types of amœbæ. These organisms retain their normal motility for at least thirty minutes, even in high concentrations of protein, in which they appear with strongly reversed contrast. In general, the clear ectoplasmic layer of a resting region contains about 8–10 per cent of solids. In active movement, however, the tip of a pseudopodium may contain less than 2½ per cent of solids. This represents a considerable redistribution of water, such as has been postulated in some theories of amœboid movement. One forms an impression that water is squeezed forward into the pseudopodium from the less active 'hind regions' of the organism and that a sudden liquefaction accompanied by streaming of granules takes place.

The human spermatozoon often contains a collar of cytoplasm just behind the head. This contains about 14 per cent solids, as in the cytoplasm of many other cells. The heads, however, are very much denser and contain about 45 per cent of solids. It is difficult to obtain precise values for the tails; but they appear to contain approximately 50 per cent solids. The flagella and cilia of other types of cells are generally also very dense and their solid content cannot always be estimated by this method. In *Euglena*, however, the solid content of the flagella is only about 20 per cent, a value not very much higher than that for the cytoplasm itself.

It seems to be a general rule that many types of cellular activity are accompanied by an increase in water content. Thus in spermatogenesis the appearance of chromosomes may be heralded by a reversal of cytoplasmic contrast. The metaphase chromosomes, in particular, are surrounded by a bright zone of low solid content.

(2) *Microbiology*. Some of the most useful applications of microrefractometry may well occur in the study of bacteria, fungi and yeasts. Many of these organisms show considerable tolerance to *p*H and tonicity, so that the preparation of the immersion medium is greatly simplified. Fully grown bacterial cultures show surprisingly little variation in the individual cells and rather precise end-points are often obtained. In general, there is little difference in the solid content of the same species grown on solid or in liquid medium, provided that the medium contains all the necessary growth factors. Thus, *Sarcina lutea* gave the same value, 35 per cent, in each medium. *Proteus vulgaris* gave values of 28·5 per cent in liquid and 29 per cent on solid media. On the other hand, *Streptococcus hæmolyticus* had a higher solid content (43 per cent) in liquid medium than on solid (34 per cent). Most bacteria so far examined have a rather higher solid content (of the order of 25–40 per cent) than have tissue cells or protozoa. The values for a given strain vary very little, once the culture is fully grown, and the reproducibility of the results, even after many months, is quite astonishing. A study of the variations of solid concentration and mass of bacteria at different stages of the growth cycle and in response to diverse metabolic conditions, including the action of antibiotics, is being undertaken. There is every indication that this technique may be a useful and novel aid in the investigation of bacterial metabolism.

Work on fungi has suggested a variety of interesting problems. The solid content of fungal mycelia varies along their length, and only measurements of the young, actively growing tips are used as a basis of comparison. Nearly twenty species of *Penicillium* have been measured, and the solid content of the active regions is remarkably constant, the extreme values being 24–28 per cent. In *Rhizopus* and *Absidia*, two zygomycetes, however, the value is only about 15 per cent. Such differences may perhaps have some taxonomic bearing.

The behaviour of fungal spores is particularly striking. When a group of spores is examined in certain concentrations of protein some appear bright while others remain dark, in positive phase-contrast. Such spores were actually grown on the slide in the immersion medium. The bright spores invariably germinated and a bright mycelium grew out. The complete growth-cycle to the formation of new spores could be observed. The dark spores remained dormant, or if they germinated, always passed through a stage of reversal of contrast. Here again it appears that cellular activity is accompanied by an increased water content. So far as is known, this is the first time that it has been possible to distinguish spores which are about to become active from dormant ones. Another observation may throw some light on the sexual differentiation of fungi. In *Absidia glauca* the two progametangia which come into contact from different hyphæ show a distinct difference in refractive index. Thus, in 7·5 per cent protein one appears dark and the other bright. Again, this is perhaps the first indication of a structural or chemical difference which could not be revealed by classical methods.

The economic importance of yeasts makes their study particularly desirable. Both brewer's and baker's yeasts have been found to have an exceptionally high solid content (40 per cent) in the cytoplasm of resting cells. The vacuoles give very low values, and the water content of the cytoplasm rises sharply during active budding. As will be indicated below (section 5), the immersion method greatly assists the cytological study of yeast cells by phase-contrast microscopy.

(3) *Studies on cell permeability and death.* An investigation has been carried out in this laboratory into the action of fixatives on living cells[9]. For this reason an attempt was made to study the changes in refractive index produced by different fixatives. The immersion method failed completely, however, and it was never possible to make a fixed cell appear with reversed contrast. The reason for this is presumably that the dead cell becomes permeable to external protein, so that the external concentration never exceeds the internal one. This suggests a new and simple test for cell death or increased permeability, and there is much evidence to support this hypothesis. It may prove possible to detect earlier stages of damage by using solutions of substances of lower molecular weight, and experiments of this type are now in progress. Among the substances we have tried are preparations of peptone and of polyvinyl-pyrrolidone. These are apparently toxic in high concentrations (exceeding about 15 per cent), but amœbæ, for example, can tolerate them for reasonable periods in concentrations of about 12 per cent, and the values for refractive index obtained with protein have been confirmed with both substances. Although most bacteria and fungi so far studied do not show reversal of contrast in concentrated peptone or polyvinyl-pyrrolidone, yeast cells can be reversed by dialysed peptone. This behaviour may possibly be related to differences in the nature of the membranes of these micro-organisms. If some cells, for example, snail spermatocytes, are immersed in high concentrations of polyvinyl-pyrrolidone, both nuclei and cytoplasm may be reversed at first. In a few minutes, however, the cytoplasm becomes dark, but the nucleus remains bright. This suggests that the cell membrane becomes permeable to the material, but the nuclear membrane remains impermeable. The advantages of a simple visual method for studying changes in cell permeability are obvious.

(4) *Hæmatology.* The mammalian red cell can be regarded as a membrane containing a concentrated solution of hæmoglobin. The latter is the major constituent of the cell, and accounts for more than 97 per cent of the total solids, including stroma[11]. Thus, refractometry of red cells is essentially a new method of hæmoglobinometry and one, moreover, which determines a very fundamental quantity in clinical hæmatology, namely, the corpuscular hæmoglobin concentration. Again, this quantity can be determined on individual cells and not, as hitherto, as an average figure for millions of cells. The actual range of concentrations in the cells of any individual can be determined, and work has begun on the task of plotting actual distribution curves showing the relative number of cells containing a given hæmoglobin concentration. Such curves are reminiscent of the familiar Price-Jones distribution curves of red-cell diameter, and despite the considerable labour involved, they must be computed and subjected to statistical analysis in order to understand the nature of normal and pathological variations of the red-cell population.

A survey of various types of blood diseases is being carried out with the collaboration of the Department of Clinical Pathology of the Radcliffe Infirmary, Oxford, and full details will be reported elsewhere with Dr. J. B. Howie. It may be mentioned that the picture in iron-deficiency anæmia is a very clear-cut one. The scatter is usually greater than normal, but the highest members of the population rarely reach the concentration of the normal median. Even quite mild cases of iron deficiency with blood hæmoglobin as high as 80 per cent can be rapidly detected by this method. In pernicious anæmia, on the other hand, the range seems to be shifted in the opposite direction with a median slightly higher than normal, and many members of the population contain concentrations considerably higher than normal. Thus, contrary to current opinion, our results suggest that pernicious anæmia is, in fact, an example of a true hyperchromic anæmia with a raised corpuscular hæmoglobin concentration in some cells, and not simply a normal hæmoglobin concentration with larger cells.

Another hæmatological application which may be of practical value is the recognition of 'dead' cells or functionally abnormal red cells. In section (3) above we stressed that reversal of contrast could only be obtained with living cells. With the present technique we have never found any normal cells which were not reversed in 38 per cent protein solution. If a preparation of normal cells is left to stand over-night in this strength of protein, a proportion of the 'bright' cells becomes dark. Similarly, if a suspension of 'bright' cells is damaged, for example, by narcotics or by sub-hæmolytic concentrations of lytic agents, a number of cells, depending on the degree of damage, become dark. Presumably these cells are 'leaky' and allow the protein to penetrate into their interiors. Blood stored in a refrigerator begins to show a gradually increasing proportion of 'leaky' cells after some time, and this proportion is rapidly increased by keeping the blood at room temperature. It is hoped to devise a simple and rapid test for determining whether a given specimen of stored blood from a blood bank is suitable for transfusion.

Many hæmatological problems remain to be investigated. Apart from the determination of normal and abnormal distribution curves, there are questions associated with the change-over from the fœtal type of hæmoglobin to the adult type, the nature of hæmolytic anæmias, the changes which occur during treatment of anæmias, the possible alterations which blood cells undergo in the spleen, the effect of various anticoagulants, and the influence of different substances on the survival of stored blood.

(5) *Contrast variation in phase-contrast microscopy.* In order to obtain the maximum information from the phase-contrast method, it is essential to vary the refractive index of the mounting medium[12]. This has not hitherto been possible in the case of living cells, and some of these have been regarded as unsuitable for phase-contrast work. Thus, many spherical cells are very refractile and are surrounded by intense and disturbing haloes when examined in saline or plasma media, so that little or no internal structure can be made out. Such haloes can be greatly reduced by immersion in suitable protein solutions, and cytological details can then be readily studied. The method is particularly useful with refractile structures such as yeasts, spores, and some plant cells. The immersion method can also be used for the measurement of birefringence of living cells as already foreshadowed[13].

(6) *Spectrophotometry of cell suspensions.* Suspensions of cells mounted in saline or nutrient media are very cloudy and scatter light. If, however, the refractive index of the cells is determined and they are then suspended in a medium of about the same refractive index, light scattering is greatly reduced and the suspension becomes virtually transparent. Concentrated suspensions of blood cells, for example, can be clarified in this way[14]. It now becomes possible

to carry out spectrophotometry on such material much more accurately and with much more concentrated suspensions than hitherto, and the state of pigments, enzymes, etc., in living animal and plant cells and micro-organisms can be investigated. Results obtained by this method will be reported in detail by one of us (R. B.).

(7) *Combination of refractometry and mass determination.* By means of interference microscopy it is possible to determine the product of refractive index and thickness, and hence the dry mass of a living cell[15,9]. Although refractometry and mass determination are closely related, the information given by the former, that is, the concentration of solids, is generally more fundamental. Thus the knowledge of the actual mass of a structure like an amœbal pseudopodium is of no great interest, because it depends on the size of the pseudopodium, which may be varying rapidly. The local concentration of solids is of much greater value. When the two methods are combined, however, it is possible in principle to obtain a considerable amount of useful information about living cells. If the product of refractive index difference and thickness and the refractive index itself are measured, the thickness can be calculated. The integrated product of thickness and projected cell area then gives the cell volume. Thus, from two optical measurements it is possible to derive (1) the dry mass of part or the whole of a cell, (2) the concentration of solids in different parts of the cell, (3) the cell thickness, (4) the cell volume, (5) the concentration of water in different regions, (6) the total mass of water. Such facts provide a useful basis for much quantitative work on living cells.

This work was made possible by grants for apparatus from the Royal Society and the Rockefeller Foundation. Generous assistance was also provided by the Nuffield Foundation and the Smith, Kline and French Foundation.

# FLAVOUR ASSESSMENT

A SYMPOSIUM on flavour assessment, in which the Food Group of the Society of Chemical Industry, the Biological Methods Group of the Society of Public Analysts and the Biometric Society joined, was held on the afternoon and evening of Wednesday, March 11, at the Wellcome Research Foundation, Euston Road, London. The chairman of the Food Group, Prof. H. D. Kay, took the chair at the afternoon session, and Dr. H. O. J. Collier, of the Society of Public Analysts, and Dr. Katherine Coward, of the Biometric Society, at the after-tea and evening sessions. Some two hundred and thirty people were present.

The first speaker was Dr. E. D. Adrian, who discussed the physiological background of flavour assessment. He pointed out that while the strict physiology of the sense-organs tells us little about the sensations experienced by the individual, which are elaborate constructions of the central nervous system, the physiologist can tell us a good deal about the kind of information which comes in when the end organs are stimulated. The concept presented to consciousness is an edited synthesis of this information; in the case of our appreciation of food and drink, it depends both on the signals coming from the eyes as well as the nose and mouth, and also on the idiosyncratic likes and dislikes acquired during our upbringing and past experience. The physiologist deals with the stage where the environmental change is analysed by the sense organs; he can measure the size, number, grouping and spacing of the brief impulses travelling up the sensory nerve fibres.

The flavour of food is signalled by the taste buds in the tongue and the back of the mouth and the large olfactory organ at the back of the nose. In man, the olfactory organ, which has an area of about 2 sq. cm. on either side, contains several million long, sensory cells, each ending in a hair-like process which projects into the surface layer of mucous and water on the surface of the organ.

With smells, there has always been the difficulty of making any classification or analysis of the qualitative aspects, or of producing a scale of smells. Recent research has left the sensation out of account and recorded the signals which the sense organ sends to the brain. Experiments have been carried out with the rabbit, which has a large olfactory organ, to determine the character of the impulses—changes in electrical potential—passing along the olfactory nerve after a measured stimulus, consisting of a definite quantity of the vapour of a chemical substance of known composition, has been brought to the olfactory surface within a definite and fairly short time. Dr. Adrian showed a number of slides recording those impulses.

With a similar stimulus, the time course of the discharge of impulses is characteristic, and may help the animal to distinguish one smell from another. The esters and substances soluble in water seem to act more rapidly than those only soluble in lipoids. It is possible that there may be different types of reception, perhaps depending on the distance of the cell nucleus in the long sensory cell from the receptor hairs. Thus air which has passed over coffee gives a group of potential spikes on the record of the discharge differing from that given by air which has passed over tea. When pure chemical substances are tried, there seems to be at least four classes of substances of which the discharge patterns can be distinguished. This is most obvious when the stimulus is not too far from the threshold, that is, when only a few conducting units are in action.

How the stimulating molecules of the odoriferous substances excite the end organs is a different problem; but at least we know that the olfactory organ sends the same sort of messages into the brain as the other sense organs, and that judgments of flavour are based on a central editing and synthesis of signals arriving via a fairly large number of afferent channels.

Mr. H. G. Harvey (British Food Manufacturing Industries Research Association) dealt with certain basic considerations in regard to flavour assessment from a somewhat different angle. In the well-fed human, the reaction to flavour is still primitive and largely confined to like or dislike, or preference of one food to another, though many separate sensory messages associated with colour, temperature, texture, taste, odour, obviously enter into any such judgment. Mr. Harvey emphasized the importance of visual appearance, quoting Moir's experiment where table jellies with colours not conforming to the flavours customarily associated with these colours were tasted by a large group of people, most of whom failed to allocate the flavours correctly. When food intended for sale to persons of normal vision is being tested for flavour, the normal association of colour and flavour should be allowed to operate.

Nearly every type of tasting test, Mr. Harvey pointed out, falls into one of two categories: (1) consumer preference and (2) grading, though the way in which particular assessments are made varies widely. A sound statistical planning is necessary, whatever method is used. Mr. Harvey compared, with examples, the 'paired comparison' method and the 'triangular' test, where three samples, of which two are identical, are presented to each assessor. He considered that assessors should, where possible, be given the simplest possible judgment to make. Assessors vary greatly in their discrimination for reasons that are usually obscure, though non-smokers do not seem to show any significant difference in tasting ability from smokers.

Mr. A. S. C. Ehrenberg (Institute of Psychiatry, Maudsley Hospital, London) and Dr. J. M. Shewan (Torry Research Station, Aberdeen), in a paper on the objective approach to sensory tests, illustrated their conclusions from a study of present-day methods of preserving fish in palatable form, using carefully trained taste panels for the assessment of qualities which go a little beyond simple flavour. They endeavour to measure 'eating quality', grading this variable on a ten-point scale, each point of which is given a detailed description. The panel is trained to agree on the association of the descriptive terms and the place on the scale. A major difficulty is to decide whether or not the level of assessment remains reasonably constant over a period of time; quick-frozen fish stored at low temperatures show little change over months of storage and have some value as standards; also, objective chemical measurements (total volatile bases) seem to agree fairly consistently with the position on the 'eating quality' scale given by the organoleptic assessments.

Mr. J. M. Harries (Ministry of Food) also spoke on specialist grading tests and consumer acceptance trials. The consumer acceptance or preference tests, the results of which vary with standards of living, have usually a wide scatter of individual results about an average. When attempting to forecast consumer preference, the scatter is as important as the average. The relation of this variation to the economic concept of elasticity of demand was discussed. In consumer preference tests, the food should be presented in the form in which it is normally used. One method employed is to offer five samples, three (identical) of one kind, two (identical) of another—a method useful in assessing the effect of alternative treatments on the flavour of a given food.

For specialist grading tests, a limited panel of individuals of trained acuity is used; such tests are not concerned primarily with likes and dislikes but are meant to effect a sensory analysis of flavour or other food characteristics, previously formulated in as precise a way as possible, and discussed beforehand by the panel. By such means, it is often possible to place different samples in a consistent order, or on a numerical scale. Mr. Harries reviewed some of the statistical methods of dealing with the test data.

Dr. J. O. Irwin (London School of Hygiene and Tropical Medicine) gave an interesting statement of the biometrician's point of view. There has been in the past a good deal of doubt as to the legitimacy of speaking of the measurement of sensation, and whether the only measurable quantities are the stimuli that evoke the sensation. His view is that the attempt to provide and classify such measurements has, nevertheless, to be made. He referred to the classification proposed by Chambers into (1) nominal, (2) ordinal, (3) interval and (4) ratio scales, and briefly described the use and limitations of each of these scales. The pragmatic approach to ordinal scales, not infrequently used in flavour assessment, is often better than a too pedantic use of a precise form of metric—an example was given of this from results on bacterial plate counts of milk. The biometric assessment of the properties of food, such as odour or flavour, is a type of assay not too dissimilar from, say, the biological assay of the amount of insulin in a given preparation.

Dr. Irwin directed attention to a valuable publication by the U.S. Department of Agriculture, namely, Bulletin No. 34 of the Bureau of Human Nutrition and Home Economics, 1950, in which a thorough examination of many aspects of the 'specialist grading' type of test is given. He ended his talk by scrutinizing from the biometric point of view some of the findings mentioned by the previous speakers.

A short discussion followed the conclusion of each of the five papers presented.

# OBITUARY

## Dr. Marc Daniels

Dr. Marc Daniels, a member of the Tuberculosis Research Unit of the Medical Research Council, died in London on March 3 at the age of forty-six. Educated in Manchester and Paris, he took his British medical qualification in 1937 and, a few years later, entered the public health field. After two years in Lincolnshire, however, he gained a scholarship at the Royal College of Physicians, a committee of which was directing a survey on the epidemiology and prevention of tuberculosis in young adults, under the Prophit Trust. From this point Daniels concentrated upon tuberculosis, and, after outstanding work in this survey during 1942–45, and in the preparation of its important report, which among other beneficial effects led to the official recognition of tuberculosis in nurses, laboratory workers and certain other categories as an industrial disease, he joined UNRRA as a consultant in post-war Europe. Some of his observations in this sphere were recorded in his Milroy Lectures to the Royal College of Physicians in 1949.

In 1946 Daniels joined the staff of the Medical Research Council, and thereafter was responsible for the practical co-ordination of two important lines of inquiry undertaken by the Tuberculosis Research Unit under the direction of special committees of the Council. One of these was the controlled trials of BCG and vole bacillus vaccines in the prevention of tuberculosis in school-leavers, now being conducted in Birmingham, Manchester and the Home Counties; the other was the nation-wide trials of the newer chemotherapeutic agents in human tuberculosis (streptomycin, *p*-aminosalicylic acid and isoniazid, the latter being still under test). Although Daniels's most abiding interest lay in epidemiology, his reputation was most enhanced by these—the first strictly controlled—chemotherapeutic trials in tuberculosis; the reports, prepared by him for the committee, received highly favourable comments in many countries, as much for their methods as for their content. Indeed, one of his main scientific contributions was the successful application of statistical methods to group studies in clinical tuberculosis. With the services of Prof. Bradford Hill as statistical designer, and of Daniels as organizer, these trials constituted an advance in the evaluation of new drugs in acute and chronic disease. While occupied with this work, Daniels served on many missions concerned with tuberculosis, for the Foreign Office, the British Council, and the World Health Organization; he was a member of the Streptomycin Sub-committee of W.H.O.'s Expert Tuberculosis Committee.

Daniels brought enthusiasm, precision and modesty to all his work, and he developed many friendships at home and abroad. Having a world outlook on health problems, he was very conscious of the moral and social responsibilities of medical men and scientists in a world needing peaceful development, but subjected to increasing strains and the threat of destructive uses of medical and scientific skill; and he was interested in the Medical Association for the Prevention of War from its formation. He had for many years been a member of the Association of Scientific Workers. He had many other interests, showing discriminating appreciation of art and drama, in both of which he took personal part. Daniels had two daughters by his first marriage, to Anne Burgess. In 1949 he married Kay Graw.

P. D'Arcy Hart

## NEWS and VIEWS

### Geography at Oxford:

#### Prof. K. Mason

Prof. K. Mason retires from the chair of geography in the University of Oxford at the end of this academic year, after twenty-one years service. He went to Oxford from the Survey of India, at a time when the last of many proposals for an Honour School in Geography was receiving favourable consideration from the University, and thus became heir to the Oxford tradition in geography. He wisely accepted the proposals without serious change and concentrated his efforts on making the new School work smoothly, on collecting a well-qualified staff, and, most successfully, on securing a building which could adequately house the growing number of students reading geography. The splendid lecture theatre, in the design of which he took an active part, is a fitting memorial to this side of his activities. Not least of his services was to induce the Drapers Company to provide three travelling scholarships. Under his administration the numbers have grown continuously from a mere handful in 1932 to about 180 in the present year. He leaves the Honour School of Geography at Oxford firmly established and well fitted for further expansion.

#### Mr. E. W. Gilbert

Mr. E. W. Gilbert, who succeeds Prof. Mason, is the first Oxford man since the days of Sir Halford Mackinder to direct the Oxford School of Geography. Like Mackinder, he began by taking the Honour School of Modern History—in 1922. He then gained all the distinctions possible at Oxford before the days of an Honour School of Geography, including the degree of B.Litt., for a thesis on the exploration of Western America, afterwards published by the Cambridge University Press (1933). Mr. Gilbert's first teaching post was at Bedford College, London. He next became joint head of the newly established Honour School of Geography in the University of Reading. He returned to Oxford in 1936 as Rockefeller research lecturer in human geography, and seven years later became reader in human geography. Most of his very large number of contributions to geography deal with the human and regional aspects of the subject, and this fact alone is some guarantee that the traditions of Oxford geography will be maintained. Moreover, Mr. Gilbert begins his career as professor with a full knowledge and experience of the Oxford School of Geography. Oxford is fortunate in retaining the services of one of her most devoted sons; the School of Geography has now an experienced and very competent staff; and Mr. Gilbert is fully qualified to maintain the high standards set by his predecessors.

### Meldola Medal, 1952

The Meldola Medal is the gift of the Society of Maccabæans and is awarded each year to the chemist who, being a British subject and less than thirty years of age on December 31 in that year, is considered to have shown the greatest promise as indicated by his or her published work. On the recommendation of the Council of the Royal Institute of Chemistry, two candidates have been adjudged equal, and therefore two Medals have been awarded for 1952 to T. L. Cottrell and Dr. B. C. L. Weedon, respectively.

#### Mr. T. L. Cottrell

Mr. Cottrell graduated in 1943 from the University of Edinburgh and joined the Research Department of the Nobel (then Explosives) Division of Imperial Chemical Industries, Ltd. There he worked in the Organic Research Section until 1946, when he was sent to study in the Physical Chemistry Laboratory in Oxford and investigated the thermo-chemistry of the ionization of some organic acids and also some theoretical problems connected with molecular structure. On his return in 1948 to the Nobel Division, where he is now in charge of the Physical Chemistry Research Section, Mr. Cottrell became interested in the properties of gases at high temperatures and pressures, and in aspects of chemical kinetics. Using a simple quantum mechanical model, he investigated the effect of density on molecular energy and, in collaboration with Dr. S. Paterson, used the results to derive an equation of state which could be applied in the calculation of the velocity of detonation of condensed explosives. In the course of this work an investigation was made of the conditions under which the virial theorem holds in such calculations. In chemical kinetics he has made a study of the pyrolysis of nitrocompounds, distinguishing between bond breaking and unimolecular mechanisms and, in addition, is at present doing theoretical work on rates of energy transfer in gases.

### Dr. B. C. L. Weedon

Dr. Weedon was educated at Wandsworth School and at the Imperial College of Science and Technology, London, and, after graduating in 1942, worked at the Imperial College on the reactions of acetylenic alcohols. He later joined Imperial Chemical Industries, Ltd. (Dyestuffs Division), and spent two years in the research laboratories at Blackley. In 1947 he was appointed to his present position as lecturer in organic chemistry at the Imperial College, and, with Sir Ian Heilbron, until the latter relinquished his chair, and then independently, he worked on compounds of the vitamin A type; as a result, several features in the relationship between biological (growth-promoting) activity and molecular structure were elucidated. Dr. Weedon has been working in the carotenoid field and has developed routes to the synthesis of methylbixin and some related compounds. Another of his current interests is in fatty acids, and he is also associated with Prof. R. P. Linstead in developing anodic reactions of preparative value in organic chemistry. Such methods have, for example, been found to provide convenient routes to a wide variety of straight- and branched-chain, saturated and unsaturated, fatty acids. During this research a novel route to some vinyl*cyclo*propanes was encountered.

## New Zealand Department of Scientific and Industrial Research

Mr. F. R. Callaghan has recently retired from his post as secretary to the council and permanent head of the New Zealand Department of Scientific and Industrial Research, and has been succeeded by Dr. W. M. Hamilton, assistant secretary in control of the agriculture and biology branches of the Department. Mr. Callaghan is a graduate of Canterbury University College, Christchurch, and after a period of teaching in the South Island he was appointed in 1916 as instructor in agriculture to the Auckland Education Board. In 1926 he was in charge of the New Zealand Government Court at the Wembley Exhibition, London. Then, in 1927, he joined the newly formed Department of Scientific and Industrial Research, and from the first took a major part in the establishment of the Department on sound lines, helping the secretary in the formidable task of establishing, equipping and staffing the many new units of the Department. In 1936 he also became chief executive officer of the Plant Research Bureau, which comprised the Plant Diseases Division, the Grasslands Division, the Crop Research Division, the Entomological Research Station, and the Botany Division, and he was largely responsible for the development of agricultural research in the Department. Mr. Callaghan was officially appointed assistant secretary in 1935, deputy secretary in 1939, and finally secretary and permanent head in 1947 in succession to Dr. E. Marsden. During his service with the Department he has seen it grow from a small beginning to a large organization of great importance to New Zealand science, and the success of this expansion is in no small way due to his efforts. His successor, Dr. Hamilton, was educated at Auckland University College and Massey Agriculture College, gaining the degree of D.Sc. for his survey of the dairy industry. He joined the Department in 1936 and in 1941 deputized for Mr. Callaghan as chief executive officer of the Plant Research Bureau. He was appointed assistant secretary in charge of the agricultural and biological branches in 1948.

## Research Expenditure in the United States

Federal expenditure in the United States on scientific research and development during 1952 was 1,839 million dollars, according to the National Science Foundation, and is estimated as 2,189 million dollars for this year and 2,327 million in 1954. Of this expenditure, the Department of Defence accounted for about 72 per cent in 1952, the Atomic Energy Commission for 14 per cent, and the National Advisory Committee for Aeronautics and the Federal Security Agency for 4 per cent each, with a little more than 3 per cent for the Department of Agriculture. The distribution ratios for the 1953–54 estimates are similar. These figures may be compared with those given for industrial research and development in a preliminary report issued by the Research and Development Board, Department of Defense (Washington 25, D.C.). Based on a survey made during the middle of 1952 of about two thousand companies that are estimated to handle 85 per cent of all industrial research and development in the United States, this report indicates that the co-operating companies spent nearly two thousand million dollars on research and development in 1951, half of which was financed by the Federal Government, and 97 per cent of this government programme was sponsored by the Department of Defense and the Atomic Energy Commission. The survey covered some ninety-four thousand scientific workers and engineers and a hundred and forty thousand supporting workers; of all these, more than half were employed in the electrical machinery, aircraft and chemical industries. Nearly 90 per cent of the scientific workers and engineers were working in manufacturing industries, and 55 per cent in the electrical machinery, aircraft and chemical industries; more than a third were employed by less than twenty companies which have research staffs of a thousand or more, and less than 2 per cent were employed by six hundred companies with staffs of less than five professional workers. The electrical machinery, aircraft and chemical industries account for 55 per cent of research expenditure, but the chemical industry, which ranks third in respect of expenditure on research, received only 7 per cent of its expenditure from Federal funds. The report refers to a greatly increased rate of turnover of scientific workers and engineers and to the vulnerability of industry engaged on defence research programmes to demands of military service.

## Royal Scottish Forestry Society: Centenary Endowment Fund

In February 1954 there will be an important forestry centenary, for, a hundred years previously, the Royal Scottish Forestry Society, the senior forestry society in the British Commonwealth, was founded. Particularly from the beginning of the eighteenth century, many Scottish landowners had pioneered in planting, and, in the middle of the nineteenth century, interest had been quickened by the introduction of conifers from the Pacific slope of what was to become the north-west States of the United States and British Columbia. From its foundation, the Society has stimulated and co-ordinated interest and the development of forestry in Scotland; but its influence has been felt far beyond the bounds of that country. It helped to promote the establishment of chairs in forestry in the Universities of Edinburgh and Aberdeen, and it continues to strive to extend education in forestry. The Society has taken a leading part in advocating the need for a national forest policy and a State forestry department, and in the latest post-war period it has helped directly and indirectly to mould government policy in relation to private forestry. Like many societies in these days, its income is proving inadequate for its necessary activities; a Centenary Endowment Fund of £10,000 is therefore being started. Donations should be sent to the Treasurer, Royal Scottish Forestry Society, 7 Albyn Place, Edinburgh, 2.

## Nuclear Research in Yugoslavia

The growth and development of nuclear research in Yugoslavia, and of the Institut de Recherches sur la structure de la Matière at Vincha, near Belgrade, is mainly due to the efforts of Prof. P. Savich, the present head of the Chemistry Laboratory. When, late in 1948, the building of the Institute was commenced, Prof. Savich was one of the only two men of science in Yugoslavia who could claim any previous experience of nuclear physics. Since then, however, about a hundred young physicists, chemists, mathematicians and engineers, many of whom have been trained in Yugoslav universities, have been gathered together to form the physics, chemistry, applied mathematics, electronics and biological sections of the Institute. The present director is S. Dedijer, and Dr. R. J. Walen is in charge of the physics section. The Institute possesses a Cockcroft–Walton type of accelerator, giving 1·5 MeV., and preliminary studies for the construction of a nuclear reactor are being undertaken. The progress made and the standard achieved may be judged from the collection of the first sixteen scientific articles published by members of the Institute, which has recently been issued (*Recueil de Travaux de l'Institut*, 1; 1952. Pp. 120; from the Institute, Belgrade). Six of the articles are in English, nine in French and one in German (with English summary). They deal mainly with instruments and techniques useful in nuclear energy research, and include articles on impulse amplifiers, a large-window rectangular β-particle Geiger–Müller counter, the fluorimetric determination of uranium in ores, the determination of feeble concentrations of heavy water, the uses of mass spectrometers, glass-to-metal seals, the structure of electrolytically deposited copper, measurements of β-ray spectra, the retardation of neutrons, and particle track lengths in photographic emulsions.

## Presentation of Technical Information

Subsequent to Prof. R. O. Kapp's lectures on "The Presentation of Technical Information", given at University College, London, in 1947, an informal discussion group was formed which, in October 1948, entered on a formal existence under the title, Presentation of Technical Information Discussion Group (Secretary: B. C. Brookes, University College, Gower Street, London, W.C.1). The objects of the Group are to interchange ideas and experience of the art of exposition, and to encourage the development of any methods of presenting technical information which promise to raise the general standard of exposition. A paper read at a meeting of the Group on November 19, 1952, by J. W. Godfrey, deals with the preparation and production of technical instruction manuals and has been issued as Group Paper D.G. No. 1. It discusses the qualifications of a technical writer, the considerations which may lead an organization to set up a technical publications unit and the problems of co-ordination which may arise in such a writing unit. Some notes are also included on difficulties, such as formulæ, in the preparation of typescript for letterpress, and on methods of production, including the production of illustrations.

## Health Education in Rumania

In the summer of 1952 Dr. S. Leff, medical officer of health to the County Borough of Willesden, visited Rumania, and he has recorded some of his impressions of health activities in that country (*Health Educ. J.*, 11, No. 1; January 1953). Before the War most Rumanian babies were born in home conditions of great ignorance and poverty; doctors and midwives were almost unknown in rural areas. During recent years the Rumanian Ministry of Health has built more than one thousand maternity hostels throughout the country, each with a doctor and midwife in attendance. These hostels are small; but, within a period of about two years, the number of mothers delivered under aseptic conditions in them rose to almost 100 per cent. The combination of measures for health education and the raising of the standard of the health services has resulted in a large reduction in the maternity mortality-rates and in the halving of the infant mortality-rates within four years. Another example of the results that can be achieved by health education is the Rumanian experience in combating typhus. Up to the end of the War, 72,000 people suffered from typhus annually, largely owing to dirt, lack of washing facilities and illiteracy. In 1952 the number had fallen to a few hundred. This was accomplished as the result of an extensive health education campaign throughout the country. The success of this campaign has been repeated with malaria, where the number of cases has been reduced from 50,000 annually to 5,000.

## Embryology of the Orobanchaceæ

*Cistanche tubulosa*, like other members of the Orobanchaceæ (Personales), is a leafless total parasite, growing on the roots of *Acacia* and other trees. In an investigation of its embryology, B. Tiagi (*Lloydia*, 15, 3, 129; 1952) has found that the embryo sac is not characterized by any unusual features, but after fertilization the embryo remains small and relatively undeveloped. In the small mature seed the embryo is an ovoid structure with tissue differentiation but without differentiation of plumule, cotyledons or radicle. The cellular endosperm forms a rather feeble chalazal haustorium but a very aggressive micropylar haustorium, with intercellular hyphal-like branches which penetrate the integument. These endosperm developments, however, are general in the autotrophic Scrophulariaceæ and are not correlated with the parasitic habit in *Cistanche*.

## Nutrition Society Conference on Scurvy

THE Nutrition Society is holding a two-day conference in Edinburgh during May 22–23, in honour of the bicentenary of the publication of James Lind's "Treatise of the Scurvy". After an opening ceremony in the University Upper Library, Surgeon Vice-Admiral Sir Sheldon Dudley will give an address on Lind, and Sir Edward Mellanby will then take the chair at the first session; the chairmen at other sessions will be Vice-Admiral Sir Alexander Ingleby-Mackenzie, Prof. R. C. Garry and Dr. L. J. Harris. Thirteen papers will be read dealing with various aspects of scurvy and vitamin C, of which six will be by authors from the United States and one each from Belgium, France and Holland. Further information can be obtained from Dr. C. P. Stewart, Department of Clinical Chemistry, Clinical Laboratory, Royal Infirmary, Edinburgh.

## The Night Sky in May

NEW moon occurs on May 13d. 05h. 06m., U.T., and full moon on May 28d. 17h. 03m. The following conjunctions with the moon take place: May 10d. 19h., Venus 4° S.; May 14d. 11h., Mars 4° S.; May 25d. 09h., Saturn 8° N. Mercury is a morning star, rising at 4h. 15m. on May 1 and at 4h. on May 15, and is in superior conjunction on May 24, after which it becomes an evening star but is too close to the sun for the remainder of the month to be favourably seen. Venus, a morning star, rises at 3h. 30m., 2h. 55m. and 2h. 20m. on May 1, 15 and 31, respectively; its stellar magnitude is about – 4·2 during the month, and the visible portion of the illuminated disk varies from 0·1 to 0·36. Mars sets at about 21h. during the month, which is an hour after the sun at the end of the month and it will then be difficult to observe. Jupiter sets at 20h. 50m. and 20h. 15m. on May 1 and 15, respectively, and is in conjunction with the sun on May 25, after which it becomes a morning star but cannot be observed during the remainder of the month. Saturn rises in the afternoon, and some time after sunset remains visible until the early morning hours; it is easily recognized by its proximity to Spica, and its stellar magnitude averages about 0·6. The $\eta$ Aquarid meteor shower is active in the early part of May and is visible in the early-morning hours. For many years it has been believed that this shower was associated with the debris of Halley's Comet, but recent work carried out by Prof. A. C. B. Lovell and his team at Jodrell Bank, University of Manchester, has thrown some doubt on this connexion, although further research is necessary before a definite pronouncement can be made. The velocities of these meteors obtained by radar methods at Jodrell Bank are less than would have been expected from the debris of Halley's Comet, but the results are not yet conclusive.

## Announcements

IN the Department of Nuclear Physics of the Australian National University, Canberra, Dr. B. D. McDaniel, associate professor of physics in Cornell University, has taken up his duties as a visiting Fulbright Fellow, and Dr. J. H. Carver, formerly of the Cavendish Laboratory, Cambridge, has been appointed a research Fellow in the Department, working with Prof. E. W. Titterton on photo-disintegration problems.

THE Royal Dutch-Shell Group of oil companies is offering a research studentship in geophysics, of value £400 a year and tenable for two to three years at the University of Cambridge, which is open to men of any nationality less than twenty-seven years old. Further information can be obtained from Mr. B. C. Browne, Department of Geodesy and Geophysics, Downing Place, Cambridge. Applications must be completed by July 1.

THE Development Commission is offering a few grants to British honours graduates for training in research problems in marine or freshwater science, which is designed to fit them for employment either in the Fishery Research Services of the Ministry of Agriculture and Fisheries and the Scottish Home Department or in a marine or freshwater biological research institute. The grants are worth £250-£350 a year, with extra university fees paid, and are tenable initially for one year, but renewable up to a maximum of three years. Application forms, to be returned by May 20, can be obtained from the Secretary, Development Commission, 6a Dean's Yard, Westminster, London, S.W.1.

THE annual Cornell University summer laboratory course in techniques and applications of the electron microscope will be given in the Laboratory of Electron Microscopy of the Department of Engineering Physics during June 15–27, under the direction of Dr. Benjamin M. Siegel. The course is designed for research workers, both in academic institutions and in industry, who have recently entered the field of electron microscopy or who are planning to undertake research problems involving applications of the instrument. Further inquiries should be addressed to Dr. Benjamin M. Siegel, Department of Engineering Physics, Rockefeller Hall, Cornell University, Ithaca, N.Y.

A SPECIAL summer course in the thermodynamics of equilibrium and non-equilibrium states will be given at the Massachusetts Institute of Technology during June 29–July 10. The course, which is designed especially for teachers, research workers and development engineers, will provide an exposition of classical thermodynamics and explore the newer extensions of the subject into the kinetics of processes in which non-equilibrium states play an essential part. Besides the general lectures, a number of special topics will be discussed, including a biography of Count Rumford (the bicentenary of whose birth at Woburn, Mass., has been celebrated this year), the thermodynamics of irreversible processes, the third law of thermodynamics, the thermodynamics of compressible fluids, and critical points and transitions of the second kind and other related subjects. Further information can be obtained from the Director of the Summer Session, Room 3–107, Massachusetts Institute of Technology, Cambridge 39, Mass.

A BIBLIOGRAPHY on cholinesterases and the anti-cholinesterase drugs is being prepared by Dr. K.-B. Augustinsson, of the Biochemical Institute, University of Stockholm (Odengatan 63, Stockholm 6), covering all published (official and unofficial) reports and patents, etc., in this field. In order to facilitate the compilation of this bibliography, Dr. Augustinsson requests that complete sets of relevant reprints be sent to him at the above address. If this is not possible, he would be very grateful for bibliographical details, and also any further information such as possible future publications and the names and addresses of librarians who might be prepared to co-operate in gathering together material.

# DEVELOPMENTS IN METHODS OF MICROSCOPY

A WELL-ATTENDED symposium and exhibition, organized by the Royal Microscopical Society (Industrial Section) in collaboration with the Spectroscopy Group of the Institute of Physics, the Optical Group of the Physical Society and the Physical Methods Group of the Society of Public Analysts and Other Analytical Chemists, was opened at King's College, London, on March 20 by Prof. J. T. Randall. Prof. Randall welcomed the co-operation of the four societies concerned, which he said is a recognition that to-day microscopy is not the servant mainly of only one discipline, but of many.

The meeting consisted of three sessions of papers in the anatomy lecture theatre, while an exhibition of apparatus was staged in the Physics Laboratories at King's College. In the first session, Dr. A. E. J. Vickers surveyed the use of the polarizing microscope in organic chemical research. Optical measurements such as refractive index, birefringence, can be made, which characterize and identify materials. He showed a number of microscopes of different design, as well as accessories such as universal stages, for meticulously orienting crystals. Polarization was also the subject of two of the five short papers of the second session. Mr. E. G. Steward showed how X-ray analysis, together with examination of birefringence, can identify components of mixed minerals. He also exhibited a simple hot stage for studying polarizing microscope interference figures of crystals at raised temperatures: 200°–300° C. could easily be obtained with negligible heat loss, cooling arrangements being unnecessary. Dr. R. Barer discussed polarization of the fluorescent light emitted by certain crystals, and suggested this might be used for determining the orientation of molecular planes.

Mr. M. G. L. Curties discussed the testing of microscope objectives with the Baker–Smith interferometer, in which shear is obtained by birefringent elements. He showed interferograms of aberrant objectives and the effect of unsuitable cover glasses and immersion oils. Dr. H. H. Hopkins spoke on the influence of the illuminating aperture on optical images. The partial coherence of the light in the object plane depends on the aperture of the illuminating system. Some results obtained by a generalization of the diffraction theory of image formation were given, including the influence of aberration and condenser aperture on images of periodic structures, of lines of negligible width and of straight edges. Dr. M. H. F. Wilkins described a solid fused-quartz ultra-violet microscope water-immersion objective of N.A. 0·90, constructed with spherical surfaces. The quartz/aluminium reflecting interfaces are internal, so that atmospheric deterioration is prevented. Photomicrographs as examples of the performance of the objective were exhibited: the same field taken in infra-red and in ultra-violet showed the relative quantities and distribution of hæmoglobin and nucleic acid in developing red cells.

Among other exhibits was a double-refracting interference microscope with variable phase, shown by Mr. F. H. Smith. The optically matched condenser and objective pairs with double-refracting components each exert a double-focus effect. The condenser illuminates axially separated planes of the specimen with the same portion of the luminous source, while the objective brings the two separated planes into coincidence in the image plane. The interference of the images is controlled by a double-refracting phase-shifting system. Prof. S. Tolansky exhibited a device for showing the profile of a surface. The shadow of a thin opaque line thrown at an angle on to a flat surface under the microscope appears straight, but if the surface is corrugated the line faithfully contours the corrugations. An infra-red reflecting microscope of N.A. 0·8 and focal length 13·5 mm. was demonstrated by Dr. W. C. Price; it is constructed with large mirrors to give a long working distance and to match the optics of an infra-red spectrometer. The focal length permits the objective to be used at the low magnifications necessary for infra-red work. Dr. P. M. B. Walker showed a densitometer for recording the density in photomicrographs by a double-beam system incorporating a circular density wedge, and he and Dr. H. G. Davies showed a photomultiplier attachment for photometric microscopy. Dr. W. E. Seeds exhibited an ultra-violet monochromator for use with a microscope of low aperture and high dispersion. It is a reflecting system involving two passages of light through a 60° quartz prism: with a line source, large field areas can be illuminated monochromatically.

In Mr. J. R. King's apparatus for examining opaque objects by fluorescence microscopy, ultra-violet radiation suitably filtered from a high-pressure compact source mercury vapour lamp is reflected on to the specimen from above by a Chapman and Aldridge illuminator with aluminized surfaces, as modified in the Beck–Chapman illuminator. A new technique for examining fine particles of such materials as coal, which is only translucent when thin, was demonstrated by Dr. R. G. H. Boddy. The particles are collected by the 'delta' technique, the deposition of the dust on a slide being watched under the microscope to obtain an adequately sized and distributed sample. The particles are then crushed by a specially designed condenser while the process is under observation, the measurements of the particles and the manner and results of crushing affording new information about them. A two-circle goniometer of unconventional design to provide a robust and simple apparatus for measuring crystal angles was exhibited by Mr. W. T. Moore and Mr. L. W. Codd. Dr. R. Barer and Dr. W. Weinstien demonstrated a microscope lamp designed to fulfil the two conflicting requirements for Kohler illumination: for high-power objectives a large aperture has to be filled, but the field of view is small, while for low-power work the field is large and the aperture small. The new lamp uses one fixed lens and two interchangeable lenses to provide combinations suited to objectives and condensers commonly used.

A historical note was struck by Mr. F. C. Grigg, who illustrated, from the Royal Microscopical Society's collections, the development of the microscope slide. Leeuwenhoek made special microscopes for individual objects: the rotating object holder later became popular, with talc windows enclosing a variety of objects. The ivory slide held the field for more than a century, and early glass slides, also with a number of objects, were long and narrow. The first 3 in. × 1 in. glass slides were covered with ornate paper covers: the present uncovered slide has now been used exclusively for upwards of fifty years.

Finally, among the exhibits was a small electron microscope shown by Mr. R. H. Horne.

The third session, a paper on cinemicrography, was given by Mr. R. McV. Weston. He discussed the apparatus and general technique of filming through the microscope and the difficulties that arise when cinecamera and microscope are harnessed together, mentioning vibration, weight, size of film and apparent changes of speed with magnification. He showed lantern slides of a number of famous pieces of apparatus and finished with a fascinating film he had made, the only one so far to have been taken at 3,000 exposures per sec. through the compound microscope: it showed what happened to the mercury at the constriction in a clinical thermometer immersed in warm water.

MARY DEMPSEY

# BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

## OPEN DAYS

During the week beginning March 23 the British Non-Ferrous Metals Research Association held open days during which, representatives of members and other industrial companies, university staffs and government scientific workers were invited to visit the laboratories at Euston Street, London, N.W.1. A total of more than eight hundred persons went during the week, and, at a press conference held on the first day, some fifty newspapers and periodicals were represented. The equipment of the laboratories was demonstrated, and the Association's present researches with some of those recently concluded were illustrated by exhibits.

The work of the Association covers every aspect of metallurgy, including extraction, melting and casting, working, mechanical and physical testing, corrosion, analysis and metal finishing. Major research projects, of which there are forty-two in hand at the moment, are selected from those problems which are of interest to groups of the Association's members and which can be more satisfactorily handled on a co-operative basis than in an individual works laboratory. Members co-operate with the Association's staff, which exceeds one hundred and fifty in number, by making available through a number of advisory committees knowledge within the industry on the problem in question; in some cases, members carry out in their own laboratories specific items in a research for which they have special facilities and try out some of the Association's investigations on a production scale for the benefit of other members.

The exhibits at the open days naturally referred mainly to the work actually carried out in the laboratories in Euston Street and were too numerous for comprehensive description. The following notes select a few items for special mention.

*Pressing of aluminium alloys.* One of the difficulties in the production of sheet-metal pressings in the aluminium–magnesium alloys, which are otherwise the most suitable for this purpose, is the appearance of markings in the less severely worked parts of the sheet due to uneven yielding. These are called stretcher/strain markings and are similar in appearance to those occurring in steels. The true nature of these markings has been investigated and the causes of their formation ascertained in the laboratories. From this basic knowledge practical recommendations for their avoidance have been made, and the effectiveness of the measures suggested has been established by works trials carried out with the collaboration of several members. The industry is now in a position to supply aluminium–magnesium alloy sheets which are not liable to these markings.

*Improvements in bronze foundry practice.* Over many years the Association's work in this field has established the principles governing the avoidance of gas and shrinkage unsoundness, and the present work is largely concerned with the application of this knowledge in industrial production. A special investigation is also being made in the use of insulated feeder-heads which not only improve the feeding of a casting but also greatly reduce both the weight of metal melted for a good casting and the labour involved in fettling.

*Titanium.* Although some exaggerated statements have been made about titanium, there is no doubt that its remarkable strength and corrosion resistance, coupled with its relatively light weight (intermediate between aluminium and steel), make it an extremely promising material for many engineering applications. The present high cost restricts very much its potential uses, but the prospects for the future are such as to make it important for Great Britain to play its share in the development of titanium alloys. The Association has investigations in this field in hand on behalf of the Ministry of Supply, and is provided with special equipment and experience in the techniques necessary for the handling of this highly reactive element.

*Prevention of corrosion.* Many of the applications of non-ferrous metals in engineering practice depend on their intrinsically high corrosion resistance, and the urge to develop better materials for particular applications is very pressing. In the field of condenser-tube alloys, the Association is pre-eminent. Aluminium brass, which is now very widely used in marine and land installations, was developed in the Association's laboratories, and the beneficial effect of iron additions in the 70/30 cupro-nickel alloy, which is widely accepted as the best all-round material for marine use, was fully established by the Association's work. This was followed by the development of copper–nickel–iron alloys of low nickel content, which are easily worked by the coppersmith and are resistant to corrosion by moving sea-water.

Similar work has been carried out on materials for the conveyance of fresh waters. For example, the occasional pitting to which copper water-pipes are subject has been traced in part to a film of carbon formed during the annealing operation which, when recognized, can easily be avoided, and in part to the absence from some waters of a naturally occurring corrosion inhibitor. Attempts are at present in hand to isolate and identify this inhibitor.

*Metal economy.* Researches designed to improve the efficiency of the manufacturing operations or to lengthen the service life in a particular application all promote the economical use of metals, and most of the Association's work comes in this category. Some researches have, however, been specifically aimed at problems in this field, such as the recovery of copper from pickle liquors, reduced consumption of zinc in galvanizing and more effective use of nickel in electroplating.

*Metal finishing.* One of the main investigations in the relatively newly formed Metal Finishing Laboratory at Euston Street is on the use of nickel in electroplating. Other researches in that field, designed to improve technique, are those on the electroplating of aluminium and on chromium deposition. The plating of aluminium is difficult, due to a tendency of the basis metal to form a film which prevents proper adhesion of the deposit. This is overcome by the initial formation of a thin zinc coating in one of two ways: chemical replacement, or electrodeposition. The conditions necessary to secure the optimum results in both these methods have been worked out, with marked improvement in industrial practice as a result.

*Analysis.* In the analytical field, the Association is responsible, apart from a vast amount of analysis required in its own investigations, for the development of new methods and apparatus. The exhibits during the open days covered an extremely wide variety of analytical methods, including the determination of gases in metals. In the chemical field great use is made of the polarograph (including derivative polarography) and of the spectrophotometer. In the field of spectrographic analysis, the Association has been responsible for a great deal of work aimed at improving the range and accuracy of the method. A direct-reading spectrograph (Quantometer) has recently been acquired, designed for the examination of copper alloys. The accuracy and field of use of this instrument are being explored in the light of its known success in the aluminium and steel industries.

# DEODAR AS PENCIL WOOD

UNTIL recently the so-called East African cedar (***Juniperus procera***) from Kenya has held sway in Britain, the United States and elsewhere as providing the highest class of pencil. Formerly the eastern red cedar of America (***Juniperus virginiana***) was widely used for pencil-making in the United States; but supplies gave out and the Kenya cedar held pride of place for the best-class and highest-priced pencil. Another tree used for this purpose in the United States is the incense cedar (***Libocedrus decurrens***), which grows in California. The use of the beautiful Indian deodar wood (***Cedrus deodara***) for pencil slats is a new idea, due to the research work undertaken at the Research Institute at Dehra Dun, and Indian Forest Bulletin No. 149 (New Series) gives a brief account of this new application*. The deodar has been extensively used in the past for other purposes: after the Sikh Wars in the Punjab (1849), the province was taken over and the British made acquaintance with the deodar, practically the only wood used by the local people, in the building of stations and cantonments; later, in the early 1860's, with the coming of the railways, the wood was in even greater demand for making sleepers.

The habitat of the deodar is the north-west Himalaya at approximately 6,500–8,000 ft. It has a strong timber, of good grain and easy to work, and is free from warpage. The trees are felled on contracts by the mountain people, converted ***in situ*** as required for logs or sleepers and floated down the mountain rivers to the part of the hills where they are collected in depots and built into rafts for the rest of the journey. The forests and work are mostly under the supervision of the government forest department. From the work done at the Institute, it is claimed that the wood makes first-class pencils. Unfortunately, its colour is light yellow; it is thought the public would be suspicious of the unusual colour, so the deodar slats are stained with a dye to a more popular colour. If the deodar pencil can be put on the market at a paying price, the results should be satisfactory, for the consumption in India to-day is about half a million gross of pencils, of which the deodar will supply the demand for higher quality pencils and save imports.

In supplies of material it is hoped to make use of part of the millions of cubic feet of sawn timber extracted every year as shipur; but perhaps more particularly to exploit the huge amount of off-cuts and small pieces left in the forest after the shipur conversion. The bulletin is silent as to the methods by which this material can be collected on the mountain-side in forests where chain-felling is not practical, and it also gives no indication as to the costs of such collection.

---

# EARTHQUAKES DURING 1952

DURING 1952 there were eighty-nine earthquakes each having a magnitude 6 or greater than 6 on the Richter logarithmic scale. The greatest two had magnitudes 8¼ and about 8¼, these being rather less than the greatest the world has known. One of the two occurred on March 4 from an epicentre near the east coast of Hokkaido, Japan. Fissures in the earth were caused, and a section of the cliff sank into the sea. Several bridges were damaged, railway lines were buckled and two trains were derailed. When buildings collapsed, fires were started. There was probably some geological fault displacement in the sea-bed also, as a tsunami with waves up to eight feet high swept the coast and swamped a fishing fleet of twenty boats at Urumai village. At least 31 people were killed and 169 injured, and there was extensive damage to property.

The other earthquake occurred on November 4 from an epicentre near the east coast of Kamchatka (see *Nature*, 170, 914; 1952). The epicentre, as calculated from observations at eighty-one observatories by the workers at the International Seismological Association Central Station at Strasbourg, was situated at lat. 52·9° N., long. 160·1° E., and the initial time was 10 hr. 58 min. 23 sec. G.M.T. The macroseismic effects in Kamchatka are not yet known, but the earthquake started a great tsunami which spread across the Pacific Ocean and reached as far as the shores of New Zealand, the Hawaiian Islands and South America.

During the past year five earthquakes were reported with a focal depth equal to, or greater than, 400 km., the one with the greatest focal depth (700 km.) being on February 11 with its epicentre in the Java Sea.

There were a number of earthquakes in or near Europe, and these included the following. On January 3 an earthquake occurred with epicentre near Hasankale in Turkey, Erzurum being affected; the shock caused damage to some 1,570 houses, and at least 94 persons were killed and 262 injured. On February 7 an earthquake at Arette in the Low Pyrenees, and on February 24 another near Worms and Ludwigshafen in the lower Rhine valley, were both felt with intensity 7 on the Modified Mercalli scale. On February 22 an earthquake took place with epicentre near Winster in Derbyshire. Chimney-stacks collapsed and walls of buildings, chiefly in the main street, collapsed; some slight damage was done in the surrounding district, and it is likely that movement took place along the Crich–Cromford–Bonsall fault. The shock was accompanied by a sound like a double explosion. On March 9 an earthquake was felt with intensity 8 at Etna in Sicily, and on the same day a strong one occurred in north-west Turkey. An earthquake with intensity 7 was felt on May 20 at El Palmar in Spain. Shocks with intensity 8 occurred on June 8 at Pierre Longue (France), on June 13 at Perivola (Peloponnese Islands) and on June 26 at Riberra Quente, Azores. On September 29 an earthquake was felt with intensity 7 at Munchhausen and Soufflenheim in the lower Rhine valley, and on October 8 there was a shock in lower Alsace with the same intensity. Twelve people were killed and a hundred injured on October 22 in an earthquake in the Adana district in Turkey.

Other earthquakes causing property damage and casualties occurred as follows. On July 21 in the Tulare Valley in southern California an earthquake caused extensive damage and several people were killed. The town most seriously affected was Tehachapi, some hundred miles north of Los Angeles. Permanent vertical ground movement at Bear Mountain fault was as much as one metre. On October 14 an earthquake from an epicentre at lat. 8·5° N., long. 83° W., near the south coast of Costa Rica, resulted in casualties and property damage, as did one on October 28 in Haiti (epicentre at lat. 18 5° N., long. 73·5° W.). On November 22 an earthquake caused slight property damage in San Luis Obispo County, California.

Reports have been received from the United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association, the International Seismological Association at Strasbourg, and from observatories at Aberdeen, Arkansas, Beograd, Cleveland (Ohio), De Bilt (Netherlands), Durham, Fayetteville (U.S.A.), Karlsruhe, Kew, Pasadena, Perth (Western Australia). Stuttgart, Toledo, Wellington and the New Zealand stations (including Fiji), and Zurich and the Swiss stations.

ERNEST TILLOTSON

# EDUCATION IN INDIA

THE first elections in free India under universal suffrage showed that a large proportion of voters had voted not for any particular cause, or person, but for the sacred bull (*Science and Culture*, 18, No. 1; July 1952). Congress, which now holds power, had long been mindful of the importance of educational reforms. So far back as the Karachi session of the Indian National Congress of 1931, a resolution was passed defining the fundamental rights of citizens and stating in its preamble that to enable the masses to appreciate what Swaraj would mean to them, Congress should provide for free and compulsory education.

Since independence, the National Government has been seriously tackling this problem. A large number of committees was appointed to consider general educational matters. Among them was the Kher Committee, which recommended that: (1) a fixed percentage of central and provincial revenues—about 10 per cent of the central and 20 per cent of the provincial—should be earmarked for education by the respective Governments; (2) about 70 per cent of the expenditure on education should be borne by Provincial Governments, including local bodies, and the remaining 30 per cent by the Central Government; (3) all contributions for education approved by the Provincial and Central Governments should be exempted from income tax.

The percentages recommended by the Kher Committee were not large. In certain States of the United States of America, nearly 30 per cent is spent on education, and in one State nearly 40 per cent. Apart from Mysore, which was already spending a larger percentage on education, no other major State, excepting a few like Bombay and Madras, have given serious attention to the Kher Committee's recommendations.

A comparison of State finances for 1951–52 shows that the total educational budget of all the States amounted to Rs. 65 crores, which is about 14·8 per cent of the total budgets of the various States against the Kher Committee's recommendation of 20 per cent. From these figures it is clear that the attempts to remove 'illiteracy' in the Indian Union has fallen short of the objective of Congress.

When Shri B. G. Kher's Committee recommended that 10 per cent of the central budget should be spent on education, it was implied that the bulk of it should be spent on higher and professional education. Ten per cent of the central budget comes to 30–40 crores of rupees, while the actual expenditure by the Central Government has varied between 3 and 6 crores.

The University Commission, appointed by Government on November 4, 1948, supported the National Planning Committee and Kher Committee's recommendation that democracy depends for its very life on a high standard of general, vocational and professional education. The academic problem has assumed new shapes. India now has a wider conception of the duties and responsibilities of universities. "They have to provide leadership in politics, administration, the professions, industry and commerce. They have to meet the increasing demand for every type of higher education, literary and scientific, technical and professional. It is for the universities to create knowledge and train minds who would bring together material resources and human energies."

The Commission found that the universities were unable to carry out these responsibilities because their finances were totally inadequate.

Like the Kher Committee, it recommended that the Central Government should make large grants for higher education through a properly constituted agency.

The Commission is aware that the Central Government has taken the responsibility of maintaining the Universities of Banaras, Aligarh and Delhi (and now, the Visva Bharati), and that a large amount of money has been given as grants to meet the needs of these universities. While welcoming and appreciating the grants that have so far been given, the Commission has suggested that, even though grants to other universities are mainly provincial responsibilities, they should also be the concern of the Central Government at least so far as postgraduate education and research are concerned. The Commission noted with appreciation that grants to universities have been given by the Government of India in recent years, but hoped that there would be a more systematized method of giving these grants on the advice of a responsible body.

# MICROSOMAL PARTICLES OF NORMAL COW'S MILK

By Dr. R. K. MORTON

Biochemical Laboratory, University of Cambridge*

HITHERTO, cow's milk has been considered to contain particulate components belonging to three categories, namely: (1) blood cells, leucocytes, bacteria and other readily sedimentable 'foreign' material; (2) butterfat globules; and (3) particles of the casein – calcium phosphate complex. However, it has recently been shown that lipoprotein particles, with which the alkaline phosphatase is firmly associated, also occur in milk[1,2]. Disruption of the lipid-protein bonds by treatment with *n*-butanol releases the alkaline phosphatase into true solution[1,3].

In order to obtain the lipoprotein particles, whole milk was centrifuged (2,500 *g*, 45 min.) and the cream layer removed and repeatedly washed with distilled water. After churning, the buttermilk so obtained was centrifuged at high speed (14,000 *g*, 45 min.). The red-brown lipoprotein precipitate was then dispersed in distilled water.

The separated milk was also centrifuged under similar conditions to obtain a pure white precipitate of casein. In this way both the lipoprotein and casein complexes were isolated by methods expected to produce only a minimum of denaturation or other modification, although the recovery was by no means quantitative.

The properties of the two materials are compared in the accompanying table.

COMPARATIVE PROPERTIES OF CASEIN AND LIPOPROTEIN PARTICLES OF NORMAL COW'S MILK

| | Casein particles | Lipoprotein particles |
|---|---|---|
| Lipid (per cent) | 3 | 22 |
| Nucleic acid | Not determined | Present |
| Cytochrome *c* | Absent | Present |
| Enzymic activities: | | |
| Alkaline phosphatase | 0·6 | 57·2 |
| Diaphorase | Absent | 2·5 |
| Coenzyme I–cytochrome *c* reductase | Absent | 0·1 |
| Xanthine oxidase | Absent | 37·7 |
| Succinic dehydrogenase | Absent | Absent |
| Cytochrome oxidase | Absent | Absent |

Units for enzymic activities: alkaline phosphatase expressed as µmole phosphorus liberated from β-glycerophosphate/hr./mgm. nitrogen (at 37° C.), dehydrogenases expressed as µmole 2 : 6-dichlorophenol indophenol (diaphorase and xanthine oxidase) or of cytochrome *c* (coenzyme I–cytochrome *c* reductase) reduced/hr /mgm. nitrogen (at 18° C.)

The difference between the two protein complexes is immediately apparent. The relatively high lipid content (most of which is phospholipid) and the considerable enzymic activity of the lipoprotein preparation suggests that this was obtained relatively free of contaminant casein. Moreover, the very low enzymic activity of the casein precipitate indicates that it was only slightly contaminated with lipoprotein particles.

Partial separation of the casein from the lipoprotein particles has also been obtained by removing the former as paracasein by the action of crystalline rennin. However, other methods of separation, such as by precipitation of casein at the isoelectric point, with salts or with organic solvents, result in co-precipitation of the lipoprotein particles. Hence casein prepared by these methods will always contain this lipoprotein impurity, which may account for some of the heterogeneity ascribed to so-called 'purified' casein[4].

The chemical and enzymic characteristics of the lipoprotein complex as shown in the table are very similar to those of the microsomal particles from animal tissues[5]. Therefore, it is considered that these lipoprotein particles of normal cow's milk should be called 'milk microsomes'. Furthermore, since the alkaline phosphatases of milk and of mammary gland are identical, it appears that the microsomes are released into the milk from the secretory cells of the gland. The isolation of microsomes from an animal secretion without prior homogenization or other disruptive treatment indicates that these particles occur as such in the cells.

Microsomes have been considered to be derived by fragmentation of mitochondria[5,6]. However, it is clear that the milk microsomes could not have been obtained in this way. The failure to demonstrate either succinic dehydrogenase or cytochrome oxidase in any of the precipitates from milk indicates that mitochondria (with which these enzymes are firmly associated) are virtually absent. They apparently are not released into milk during normal secretion. The significance of the presence of microsomes and absence of mitochondria is the subject of further investigation.

The factors which influence the release of microsomes into milk from the secretory cells of the mammary gland have not yet been studied. It seems likely, however, that more microsomes will be released during disturbance of normal functioning of the gland, as, for example, during mastitis infection, or towards the end of lactation. The alkaline phosphatase activity of milk rises under both these influences[7,8]. Thiouracil treatment also increases the phosphatase activity of milk[9,10], in contrast to thyroxine[11]. It seems very probable that these compounds affect the release of the milk microsomes, rather than the phosphatase activity of the microsomes themselves. Therefore, caution is urged against concluding that the change in activity of milk is an indication of similar changes in the enzymic activity of the mammary gland itself[9,10].

The association of xanthine oxidase activity with microsomal particles has not previously been demonstrated. It is therefore of interest that microsomes from liver have also been found to have high activity. It now seems important to determine whether the properties of the particle-bound xanthine oxidases differ from those of the flavoprotein obtained in solution either by proteolytic or lipolytic action[12] or by butanol treatment[1].

Electron micrographs of the casein particles and the milk microsomes have shown that both are spheroidal in shape. The microsomes, however, do not show the same tendency to clump in regular forms as do the casein particles; they are much less dense and they often appear somewhat flattened. Both types of particles vary in size, from a maximum of about 250 mµ diameter, diminishing beyond the limits of resolution with the equipment available (less than 30 mµ).

---

* Present address: Department of Biochemistry, University of Melbourne, Australia.

In endeavouring to obtain an active preparation of the 'virus' responsible for transmissible carcinoma in mice, different workers have employed centrifuging, either of untreated milk[13,14], or of milk after coagulation of casein with chymotrypsin[15]. The precipitates so obtained would certainly contain both casein and microsomal particles, the latter predominating where chymotrypsin treatment was used. Comparison of the electron micrographs obtained in the present work with those of particles separated from milk of mice having mammary carcinoma[13-15] confirms this view. Consequently, the claim that virus particles have been demonstrated in the sedimented material from infective milk cannot be considered as established. Moreover, the apparent relationship between the occurrence of human breast carcinoma and the number of particles found in milk[16] might well be explained by the release of a greater number of microsomes into milk from diseased cells. This would become particularly apparent in human milk, since the casein content (0·5 per cent) is so very much lower than that of cow's milk (3 per cent). The possibility that the milk microsomes themselves may carry the infective agent which is concerned in inducing carcinoma in susceptible mice is at present being investigated.

I wish to thank Mr. R. W. Horne, formerly of the Cavendish Laboratory, Cambridge, for taking the electron micrographs. I am grateful to Dr. M. Dixon for his continued interest and advice in this work, and to the Gowrie Scholarship Trust Fund of Australia and the Agricultural Research Council of Great Britain for financial support.

# MEASUREMENT OF WIND CURRENTS IN THE SEA BY THE METHOD OF TOWED ELECTRODES

By K. F. BOWDEN
National Institute of Oceanography

It was first pointed out by Faraday that when a stream of water flows through the earth's magnetic field an electromotive force should be induced in it. Experiments made by Faraday himself, by suspending electrodes in the River Thames from Waterloo Bridge, failed to detect this e.m.f., owing to polarization of the electrodes and other experimental difficulties. Since then, measurements made on various submarine cables showed voltages related to the velocities of the tidal streams in their vicinity. In 1918, Young, Gerrard and Jevons[1] carried out experiments in the English Channel, using both fixed electrodes and electrodes towed in tandem behind a vessel. Their experiments showed clearly the existence of the induced e.m.f.'s due to tidal currents. In 1946, Longuet-Higgins[2] made measurements of the potential differences across pairs of fixed electrodes in the English Channel and gave a theoretical treatment of the potential gradients generated by water flow in a shallow channel. Since 1946 a form of equipment using towed electrodes, and known as the geomagnetic electro-kinetograph (G.E.K.), has been developed in the United States and used in a number of U.S. oceanographic and survey vessels to determine surface currents in the ocean (Von Arx[3]). The method of towed electrodes has also been used during recent cruises of the R.R.S. *Discovery II*, using quite simple equipment.

If a stream of water is moving horizontally with a velocity of $V$ cm./sec. and the vertical component of the earth's magnetic intensity is $Z$ gauss, then the e.m.f. induced in a filament of water of length $l$ cm., transverse to the direction of flow, is given by

$$E = VZl \times 10^{-8} \text{ volt.} \qquad (1)$$

Its direction is from right to left, in the northern magnetic hemisphere, as one faces downstream. If there is a conducting return path below the moving water, a current will flow, the current density $i$ being given by

$$i = E/(\rho + \rho')l,$$

where $\rho$ is the specific resistance of the moving water, and $\rho'$ may be termed the effective specific resistance of the return path. Then the potential difference measured by a voltmeter connected across a pair of fixed electrodes, distant $l$ apart, would be

$$e_1 = E - \rho li = E[1 - \rho/(\rho + \rho')]. \qquad (2)$$

If, however, the electrodes and the voltmeter are attached to a vessel drifting with the water, an e.m.f. $E$ will also be induced directly in the connecting wires, and the potential difference actually measured, $e_2$, will be the difference between this and the potential difference in the water, that is :

$$e_2 = e_1 - E = -\rho li = -\rho E/(\rho + \rho'). \qquad (3)$$

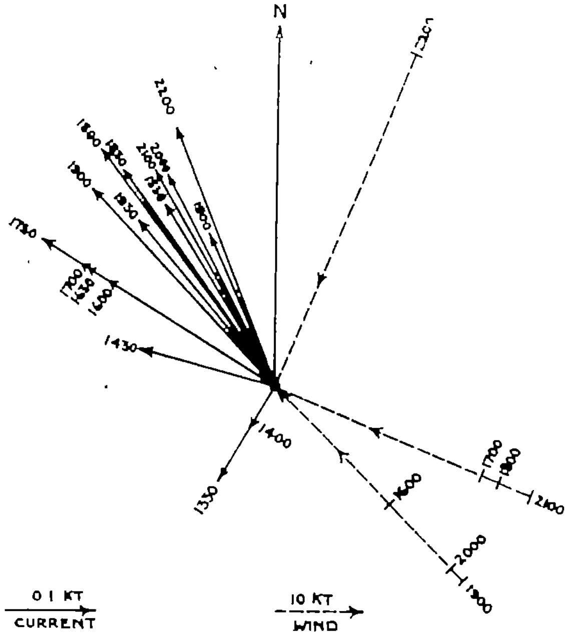
It is seen that the method of drifting electrodes is most sensitive when $\rho' \ll \rho$. This is the case when the flow extends only to a depth which is small compared with the total depth of water, so that the lower layer of water acts as a low-resistance return path for the electric current.

In the towed-electrode equipment used in *Discovery II*, the electrodes are of the non-polarizing silver/silver-chloride type, packed in glass wool in a cylindrical 'Tufnol' casing, which contains a number of holes to allow access to the water. A two-core rubber-covered cable serves for making electrical connexion to the electrodes and for towing them. The distance between the electrodes is usually 100 yd. and, with this separation, the sensitivity is approximately 2 millivolts per knot when $Z$ is about 0·4 gauss. On board, the two conductors are connected to the input of a D.C. amplifier, the output of which operates a pen recorder. A resistance-capacitance filter, with a time constant of approximately 30 sec., may be connected across the input to the amplifier, to reduce signals due to the component of particle velocity of the waves.

When the electrodes are being towed, the potential difference measured depends on the component of drift of the ship and electrode system at right-angles to the direction of towing, the forward speed of the ship being immaterial. By making observations on two courses at right-angles, the drift of the surface water may be determined in magnitude and direction. It is also necessary that a change of course of 180° should be made periodically to determine the 'zero point' of the potential difference and eliminate slow changes in the electro-chemical potentials of the electrodes. One way of fulfilling these conditions is by steaming in squares, that is, changing course by 90° at regular intervals.

The towed-electrodes method is well suited to the measurement of wind drift in deep water, since the drift is unlikely to extend to a depth greater than about 50 fathoms. An example of its use for this purpose, showing the development of a drift current following a change in the wind, was obtained during a recent cruise of *Discovery II*. At noon on October 12, 1952, *Discovery II* was in position 47° 50′ N., 12° 30′ W., in a depth of about 2,400 fm. After blowing from west-north-west during the morning, the wind had dropped to 'light airs' by noon. Soon afterwards, it started to blow from the south-east and freshened, reaching an average speed of 18 knots by 1600 hr., $25\frac{3}{4}$ knots at 1700 hr. and 30 knots at 1900 hr. A series of towed-electrode measurements was started at 1230 hr., the vessel steaming in squares, changing course by 90° every half-hour.

The accompanying diagram shows, in vector form, the drift currents as computed from these measurements. Each full-line arrow shows the direction and speed of drift, as computed from measurements on the four legs of a square, obtained during the period of 2 hr. centred on the time marked against the arrow. The corresponding wind vectors are shown by the broken-line arrows.



*Discovery II*, October 12, 1952. Current vectors, derived from towed electrode observations, and corresponding wind vectors. The time of observation is marked against each vector. At 1200 hr. the wind was reported as "light airs" and at 2130 hr. as "variable, 10 to 25 kt."

The 1330-hr. vector shows the drift as 0·12 knot, setting approximately towards south-south-west, and at 1400 hr. the drift had decreased to 0·05 knot in the same direction. The 1430-hr. vector, however, shows a drift of 0·16 knot in direction west by north. Subsequent vectors show the drift to be turning farther towards north-west and increasing in magnitude. By 1730 hr. the speed was 0·30 knot, bearing 301° (true). Afterwards the speed did not increase appreciably, although the direction continued to veer. Between 1800 and 2200 hr., the direction varied between 316° and 338°; but the variations are probably within the experimental error. Taking the mean of the determinations from 1800 to 2200 hr., the drift was 0·29 knot in direction 326°. The mean of the wind determinations from 1700 to 2100 hr. was 28 knots, blowing towards direction 308°. Thus the magnitude of the drift was about 1·0 per cent of the wind speed and its direction 18° to the right of the wind. After 2100 hr. the wind dropped, and at 2130 hr. was 10–25 knots, variable in direction. By 2200 hr. it had backed to north-north-east and increased to 40 knots. It appears from the meteorological charts that the centre of a small, but intense, depression passed slightly to the south of the ship's position at 2100 hr. The 2200-hr. drift vector (based on measurements taken between 2100 and 2300 hr.) shows no response to the change in wind direction, and could scarcely be expected to do so.

It is of interest to compare these observations with the classical theory of wind drift, due to Ekman[4]. According to the theory, the surface drift, after the steady state has been reached, should be 45° to the right of the wind (in the northern hemisphere) and its magnitude $v_s$ should be given by

$$v_s = 0{\cdot}0127\, W (\sin\varphi)^{-1/2},$$

where $W$ is the wind speed and $\varphi$ the latitude. Taking $\varphi = 48°$, gives $v_s = 0{\cdot}0148\, W$. If the water is initially at rest and a wind suddenly starts to blow and then remains steady, the surface current should reach a speed comparable with the steady-state value after about $2\frac{1}{2}$ hr., in this latitude. The direction of the surface current should approach its final value more slowly, and after $2\frac{1}{2}$ hr. should be approximately 18° to the right of the wind.

The observed drift had a speed only about two-thirds of that predicted by theory for a current generated by the local wind. The discrepancy may be due, in part, to the presence of another current constituent which is independent of, or less readily affected by, the local wind. Current charts indicate that, in this part of the north-east Atlantic, there is a general drift towards the south-east, which would be almost directly opposed to the wind drift observed on October 12, and would thus reduce its magnitude.

These observations illustrate the rapid response of the surface drift to a change in wind and show that such changes in drift may readily be determined by the towed-electrodes method, using simple recording apparatus.

Acknowledgment is made to Dr. J. T. Crennell, of the Admiralty Chemical Laboratory, for advice on the design and construction of the electrodes, to Mr. M. J. Tucker, who was responsible for the electronic equipment, and to Dr. G. E. R. Deacon and the captain and officers of R.R.S. *Discovery II* for their part in making the observations.

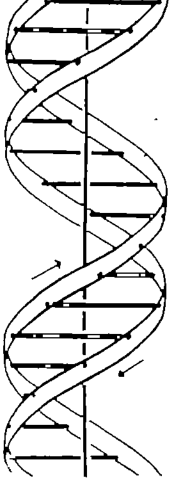
# MOLECULAR STRUCTURE OF NUCLEIC ACIDS

## A Structure for Deoxyribose Nucleic Acid

WE wish to suggest a structure for the salt of deoxyribose nucleic acid (D.N.A.). This structure has novel features which are of considerable biological interest.

A structure for nucleic acid has already been proposed by Pauling and Corey[1]. They kindly made their manuscript available to us in advance of publication. Their model consists of three intertwined chains, with the phosphates near the fibre axis, and the bases on the outside. In our opinion, this structure is unsatisfactory for two reasons: (1) We believe that the material which gives the X-ray diagrams is the salt, not the free acid. Without the acidic hydrogen atoms it is not clear what forces would hold the structure together, especially as the negatively charged phosphates near the axis will repel each other. (2) Some of the van der Waals distances appear to be too small.

Another three-chain structure has also been suggested by Fraser (in the press). In his model the phosphates are on the outside and the bases on the inside, linked together by hydrogen bonds. This structure as described is rather ill-defined, and for this reason we shall not comment on it.



This figure is purely diagrammatic. The two ribbons symbolize the two phosphate—sugar chains, and the horizontal rods the pairs of bases holding the chains together. The vertical line marks the fibre axis

We wish to put forward a radically different structure for the salt of deoxyribose nucleic acid. This structure has two helical chains each coiled round the same axis (see diagram). We have made the usual chemical assumptions, namely, that each chain consists of phosphate diester groups joining β-D-deoxyribofuranose residues with 3′,5′ linkages. The two chains (but not their bases) are related by a dyad perpendicular to the fibre axis. Both chains follow right-handed helices, but owing to the dyad the sequences of the atoms in the two chains run in opposite directions. Each chain loosely resembles Furberg's[2] model No. 1; that is, the bases are on the inside of the helix and the phosphates on the outside. The configuration of the sugar and the atoms near it is close to Furberg's 'standard configuration', the sugar being roughly perpendicular to the attached base. There is a residue on each chain every 3·4 A. in the $z$-direction. We have assumed an angle of 36° between adjacent residues in the same chain, so that the structure repeats after 10 residues on each chain, that is, after 34 A. The distance of a phosphorus atom from the fibre axis is 10 A. As the phosphates are on the outside, cations have easy access to them.

The structure is an open one, and its water content is rather high. At lower water contents we would expect the bases to tilt so that the structure could become more compact.

The novel feature of the structure is the manner in which the two chains are held together by the purine and pyrimidine bases. The planes of the bases are perpendicular to the fibre axis. They are joined together in pairs, a single base from one chain being hydrogen-bonded to a single base from the other chain, so that the two lie side by side with identical $z$-co-ordinates. One of the pair must be a purine and the other a pyrimidine for bonding to occur. The hydrogen bonds are made as follows: purine position 1 to pyrimidine position 1; purine position 6 to pyrimidine position 6.

If it is assumed that the bases only occur in the structure in the most plausible tautomeric forms (that is, with the keto rather than the enol configurations) it is found that only specific pairs of bases can bond together. These pairs are: adenine (purine) with thymine (pyrimidine), and guanine (purine) with cytosine (pyrimidine).

In other words, if an adenine forms one member of a pair, on either chain, then on these assumptions the other member must be thymine; similarly for guanine and cytosine. The sequence of bases on a single chain does not appear to be restricted in any way. However, if only specific pairs of bases can be formed, it follows that if the sequence of bases on one chain is given, then the sequence on the other chain is automatically determined.

It has been found experimentally[3,4] that the ratio of the amounts of adenine to thymine, and the ratio of guanine to cytosine, are always very close to unity for deoxyribose nucleic acid.

It is probably impossible to build this structure with a ribose sugar in place of the deoxyribose, as the extra oxygen atom would make too close a van der Waals contact.

The previously published X-ray data[5,6] on deoxyribose nucleic acid are insufficient for a rigorous test of our structure. So far as we can tell, it is roughly compatible with the experimental data, but it must be regarded as unproved until it has been checked against more exact results. Some of these are given in the following communications. We were not aware of the details of the results presented there when we devised our structure, which rests mainly though not entirely on published experimental data and stereochemical arguments.

It has not escaped our notice that the specific pairing we have postulated immediately suggests a possible copying mechanism for the genetic material.

Full details of the structure, including the conditions assumed in building it, together with a set of co-ordinates for the atoms, will be published elsewhere.

We are much indebted to Dr. Jerry Donohue for constant advice and criticism, especially on interatomic distances. We have also been stimulated by a knowledge of the general nature of the unpublished experimental results and ideas of Dr. M. H. F. Wilkins, Dr. R. E. Franklin and their co-workers at

King's College, London. One of us (J. D. W.) has been aided by a fellowship from the National Foundation for Infantile Paralysis.

# Molecular Structure of Deoxypentose Nucleic Acids

While the biological properties of deoxypentose nucleic acid suggest a molecular structure containing great complexity, X-ray diffraction studies described here (cf. Astbury[1]) show the basic molecular configuration has great simplicity. The purpose of this communication is to describe, in a preliminary way, some of the experimental evidence for the polynucleotide chain configuration being helical, and existing in this form when in the natural state. A fuller account of the work will be published shortly.

The structure of deoxypentose nucleic acid is the same in all species (although the nitrogen base ratios alter considerably) in nucleoprotein, extracted or in cells, and in purified nucleate. The same linear group of polynucleotide chains may pack together parallel in different ways to give crystalline[1-3], semi-crystalline or paracrystalline material. In all cases the X-ray diffraction photograph consists of two regions, one determined largely by the regular spacing of nucleotides along the chain, and the other by the longer spacings of the chain configuration. The sequence of different nitrogen bases along the chain is not made visible.

Oriented paracrystalline deoxypentose nucleic acid ('structure *B*' in the following communication by Franklin and Gosling) gives a fibre diagram as shown in Fig. 1 (cf. ref. 4). Astbury suggested that the strong 3·4-A. reflexion corresponded to the internucleotide repeat along the fibre axis. The ~ 34 A. layer lines, however, are not due to a repeat of a polynucleotide composition, but to the chain configuration repeat, which causes strong diffraction as the nucleotide chains have higher density than the interstitial water. The absence of reflexions on or near the meridian immediately suggests a helical structure with axis parallel to fibre length.

## Diffraction by Helices

It may be shown[5] (also Stokes, unpublished) that the intensity distribution in the diffraction pattern of a series of points equally spaced along a helix is given by the squares of Bessel functions. A uniform continuous helix gives a series of layer lines of spacing corresponding to the helix pitch, the intensity distribution along the *n*th layer line being proportional to the square of $J_n$, the *n*th order Bessel function. A straight line may be drawn approximately through the innermost maxima of each Bessel function and the origin. The angle this line makes with the equator is roughly equal to the angle between an element of the helix and the helix axis. If a unit repeats *n* times along the helix there will be a meridional reflexion ($J_0^2$) on the *n*th layer line. The helical configuration produces side-bands on this fundamental frequency, the effect[5] being to reproduce the intensity distribution about the origin around the new origin, on the *n*th layer line, corresponding to *C* in Fig. 2.

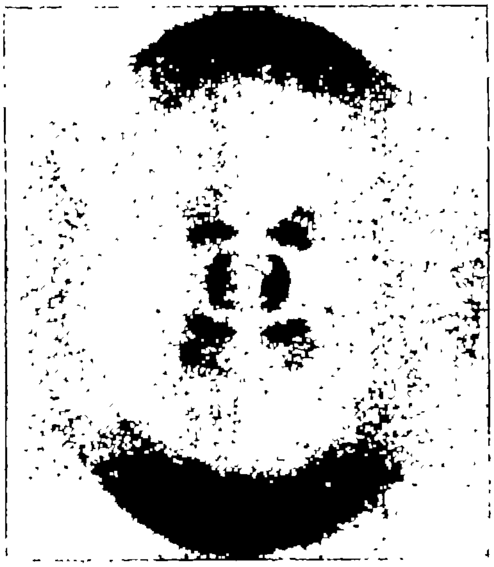

Fig. 1. Fibre diagram of deoxypentose nucleic acid from *B. coli*. Fibre axis vertical

We will now briefly analyse in physical terms some of the effects of the shape and size of the repeat unit or nucleotide on the diffraction pattern. First, if the nucleotide consists of a unit having circular symmetry about an axis parallel to the helix axis, the whole diffraction pattern is modified by the form factor of the nucleotide. Second, if the nucleotide consists of a series of points on a radius at right-angles to the helix axis, the phases of radiation scattered by the helices of different diameter passing through each point are the same. Summation of the corresponding Bessel functions gives reinforcement for the inner-

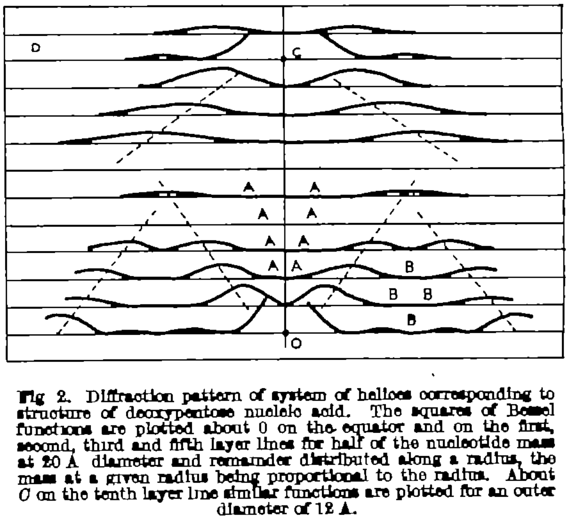

Fig. 2. Diffraction pattern of system of helices corresponding to structure of deoxypentose nucleic acid. The squares of Bessel functions are plotted about 0 on the equator and on the first, second, third and fifth layer lines for half of the nucleotide mass at 20 A. diameter and remainder distributed along a radius, the mass at a given radius being proportional to the radius. About *C* on the tenth layer line similar functions are plotted for an outer diameter of 12 A.

most maxima and, in general, owing to phase difference, cancellation of all other maxima. Such a system of helices (corresponding to a spiral staircase with the core removed) diffracts mainly over a limited angular range, behaving, in fact, like a periodic arrangement of flat plates inclined at a fixed angle to the axis. Third, if the nucleotide is extended as an arc of a circle in a plane at right-angles to the helix axis, and with centre at the axis, the intensity of the system of Bessel function layer-line streaks emanating from the origin is modified owing to the phase differences of radiation from the helices drawn through each point on the nucleotide. The form factor is that of the series of points in which the helices intersect a plane drawn through the helix axis. This part of the diffraction pattern is then repeated as a whole with origin at *C* (Fig. 2). Hence this aspect of nucleotide shape affects the central and peripheral regions of each layer line differently.

## Interpretation of the X-Ray Photograph

It must first be decided whether the structure consists of essentially one helix giving an intensity distribution along the layer lines corresponding to $J_1, J_2, J_3 \ldots$, or two similar co-axial helices of twice the above size and relatively displaced along the axis a distance equal to half the pitch giving $J_2, J_4, J_6 \ldots$, or three helices, etc. Examination of the width of the layer-line streaks suggests the intensities correspond more closely to $J_1^2, J_2^2, J_3^2$ than to $J_2^2, J_4^2, J_6^2 \ldots$ Hence the dominant helix has a pitch of ~ 34 A., and, from the angle of the helix, its diameter is found to be ~ 20 A. The strong equatorial reflexion at ~ 17 A. suggests that the helices have a maximum diameter of ~ 20 A. and are hexagonally packed with little interpenetration. Apart from the width of the Bessel function streaks, the possibility of the helices having twice the above dimensions is also made unlikely by the absence of an equatorial reflexion at ~ 34 A. To obtain a reasonable number of nucleotides per unit volume in the fibre, two or three intertwined coaxial helices are required, there being ten nucleotides on one turn of each helix.

The absence of reflexions on or near the meridian (an empty region *AAA* on Fig. 2) is a direct consequence of the helical structure. On the photograph there is also a relatively empty region on and near the equator, corresponding to region *BBB* on Fig. 2. As discussed above, this absence of secondary Bessel function maxima can be produced by a radial distribution of the nucleotide shape. To make the layer-line streaks sufficiently narrow, it is necessary to place a large fraction of the nucleotide mass at ~ 20 A. diameter. In Fig. 2 the squares of Bessel functions are plotted for half the mass at 20 A. diameter, and the rest distributed along a radius, the mass at a given radius being proportional to the radius.

On the zero layer line there appears to be a marked $J_{10}^2$, and on the first, second and third layer lines, $J_9^2 + J_{11}^2$, $J_8^2 + J_{12}^2$, etc., respectively. This means that, in projection on a plane at right-angles to the fibre axis, the outer part of the nucleotide is relatively concentrated, giving rise to high-density regions spaced *c.* 6 A. apart around the circumference of a circle of 20 A. diameter. On the fifth layer line two $J_5$ functions overlap and produce a strong reflexion. On the sixth, seventh and eighth layer lines the maxima correspond to a helix of diameter ~ 12 A. Apparently it is only the central region of the helix structure which is well divided by the 3·4-A. spacing, the outer parts of the nucleotide overlapping to form a continuous helix. This suggests the presence of nitrogen bases arranged like a pile of pennies[1] in the central regions of the helical system.

There is a marked absence of reflexions on layer lines beyond the tenth. Disorientation in the specimen will cause more extension along the layer lines of the Bessel function streaks on the eleventh, twelfth and thirteenth layer lines than on the ninth, eighth and seventh. For this reason the reflexions on the higher-order layer lines will be less readily visible. The form factor of the nucleotide is also probably causing diminution of intensity in this region. Tilting of the nitrogen bases could have such an effect.

Reflexions on the equator are rather inadequate for determination of the radial distribution of density in the helical system. There are, however, indications that a high-density shell, as suggested above, occurs at diameter ~ 20 A.

The material is apparently not completely paracrystalline, as sharp spots appear in the central region of the second layer line, indicating a partial degree of order of the helical units relative to one another in the direction of the helix axis. Photographs similar to Fig. 1 have been obtained from sodium nucleate from calf and pig thymus, wheat germ, herring sperm, human tissue and $T_2$ bacteriophage. The most marked correspondence with Fig. 2 is shown by the exceptional photograph obtained by our colleagues, R. E. Franklin and R. G. Gosling, from calf thymus deoxypentose nucleate (see following communication).

It must be stressed that some of the above discussion is not without ambiguity, but in general there appears to be reasonable agreement between the experimental data and the kind of model described by Watson and Crick (see also preceding communication).

It is interesting to note that if there are ten phosphate groups arranged on each helix of diameter 20 A. and pitch 34 A., the phosphate ester backbone chain is in an almost fully extended state. Hence, when sodium nucleate fibres are stretched[3], the helix is evidently extended in length like a spiral spring in tension.

## Structure *in vivo*

The biological significance of a two-chain nucleic acid unit has been noted (see preceding communication). The evidence that the helical structure discussed above does, in fact, exist in intact biological systems is briefly as follows:

*Sperm heads.* It may be shown that the intensity of the X-ray spectra from crystalline sperm heads is determined by the helical form-function in Fig. 2. Centrifuged trout semen give the same pattern as the dried and rehydrated or washed sperm heads used previously[4]. The sperm head fibre diagram is also given by extracted or synthetic[1] nucleoprotamine or extracted calf thymus nucleohistone.

*Bacteriophage.* Centrifuged wet pellets of $T_2$ phage photographed with X-rays while sealed in a cell with mica windows give a diffraction pattern containing the main features of paracrystalline sodium nucleate as distinct from that of crystalline nucleoprotein. This confirms current ideas of phage structure.

*Transforming principle* (in collaboration with H. Ephrussi-Taylor). Active deoxypentose nucleate allowed to dry at ~ 60 per cent humidity has the same crystalline structure as certain samples[5] of sodium thymonucleate.

We wish to thank Prof. J. T. Randall for encouragement; Profs. E. Chargaff, R. Signer, J. A. V. Butler and Drs. J. D. Watson, J. D. Smith, L. Hamilton, J. C. White and G. R. Wyatt for supplying material without which this work would have been impossible; also Drs. J. D. Watson and Mr. F. H. C. Crick for stimulation, and our colleagues R. E. Franklin, R. G. Gosling, G. L. Brown and W. E. Seeds for discussion. One of us (H. R. W.) wishes to acknowledge the award of a University of Wales Fellowship.

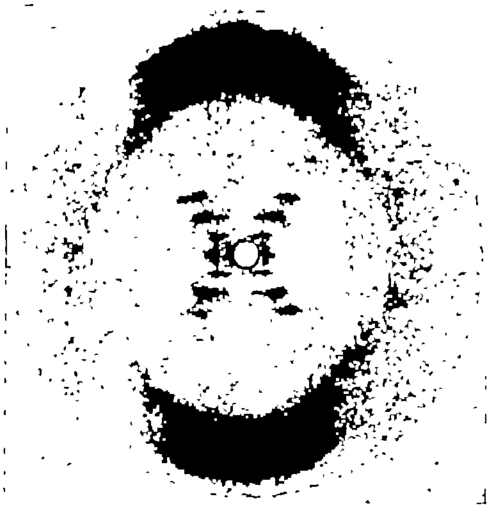
# Molecular Configuration in Sodium Thymonucleate

Sodium thymonucleate fibres give two distinct types of X-ray diagram. The first corresponds to a crystalline form, structure *A*, obtained at about 75 per cent relative humidity; a study of this is described in detail elsewhere[1]. At higher humidities a different structure, structure *B*, showing a lower degree of order, appears and persists over a wide range of ambient humidity. The change from *A* to *B* is reversible. The water content of structure *B* fibres which undergo this reversible change may vary from 40–50 per cent to several hundred per cent of the dry weight. Moreover, some fibres never show structure *A*, and in these structure *B* can be obtained with an even lower water content.

The X-ray diagram of structure *B* (see photograph) shows in striking manner the features characteristic of helical structures, first worked out in this laboratory by Stokes (unpublished) and by Crick, Cochran and Vand[2]. Stokes and Wilkins were the first to propose such structures for nucleic acid as a result of direct studies of nucleic acid fibres, although a helical structure had been previously suggested by Furberg (thesis, London, 1949) on the basis of X-ray studies of nucleosides and nucleotides.

While the X-ray evidence cannot, at present, be taken as direct proof that the structure is helical, other considerations discussed below make the existence of a helical structure highly probable.



Sodium deoxyribose nucleate from calf thymus. Structure *B*

Structure *B* is derived from the crystalline structure *A* when the sodium thymonucleate fibres take up quantities of water in excess of about 40 per cent of their weight. The change is accompanied by an increase of about 30 per cent in the length of the fibre, and by a substantial re-arrangement of the molecule. It therefore seems reasonable to suppose that in structure *B* the structural units of sodium thymonucleate (molecules on groups of molecules) are relatively free from the influence of neighbouring molecules, each unit being shielded by a sheath of water. Each unit is then free to take up its least-energy configuration independently of its neighbours and, in view of the nature of the long-chain molecules involved, it is highly likely that the general form will be helical[3]. If we adopt the hypothesis of a helical structure, it is immediately possible, from the X-ray diagram of structure *B*, to make certain deductions as to the nature and dimensions of the helix.

The innermost maxima on the first, second, third and fifth layer lines lie approximately on straight lines radiating from the origin. For a smooth single-strand helix the structure factor on the *n*th layer line is given by:

$$F_n = J_n(2\pi rR) \exp i\, n(\psi + \tfrac{1}{2}\pi),$$

where $J_n(u)$ is the *n*th-order Bessel function of $u$, $r$ is the radius of the helix, and $R$ and $\psi$ are the radial and azimuthal co-ordinates in reciprocal space[2]; this expression leads to an approximately linear array of intensity maxima of the type observed, corresponding to the first maxima in the functions $J_1$, $J_2$, $J_3$, etc.

If, instead of a smooth helix, we consider a series of residues equally spaced along the helix, the transform in the general case treated by Crick, Cochran and Vand is more complicated. But if there is a whole number, $m$, of residues per turn, the form of the transform is as for a smooth helix with the addition, only, of the same pattern repeated with its origin at heights $mc^*$, $2mc^*$ . . . etc. ($c$ is the fibre-axis period).

In the present case the fibre-axis period is 34 A. and the very strong reflexion at 3·4 A. lies on the tenth layer line. Moreover, lines of maxima radiating from the 3·4-A. reflexion as from the origin are visible on the fifth and lower layer lines, having a $J_5$ maximum coincident with that of the origin series on the fifth layer line. (The strong outer streaks which apparently radiate from the 3·4-A. maximum are not, however, so easily explained.) This suggests strongly that there are exactly 10 residues per turn of the helix. If this is so, then from a measurement of $R_n$ the position of the first maximum on the *n*th layer line (for $n$ 5<), the radius of the helix, can be obtained. In the present instance, measurements of $R_1$, $R_2$, $R_3$ and $R_5$ all lead to values of $r$ of about 10 A.

Since this linear array of maxima is one of the strongest features of the X-ray diagram, we must conclude that a crystallographically important part of the molecule lies on a helix of this diameter. This can only be the phosphate groups or phosphorus atoms.

If ten phosphorus atoms lie on one turn of a helix of radius 10 A., the distance between neighbouring phosphorus atoms in a molecule is 7·1 A. This corresponds to the P . . . P distance in a fully extended molecule, and therefore provides a further indication that the phosphates lie on the outside of the structural unit.

Thus, our conclusions differ from those of Pauling and Corey[4], who proposed for the nucleic acids a helical structure in which the phosphate groups form a dense core.

We must now consider briefly the equatorial reflexions. For a single helix the series of equatorial maxima should correspond to the maxima in $J_0(2\pi rR)$. The maxima on our photograph do not, however, fit this function for the value of $r$ deduced above. There is a very strong reflexion at about 24 A. and then only a faint sharp reflexion at 9·0 A. and two diffuse bands around 5·5 A. and 4·0 A. This lack of agreement is, however, to be expected, for we know that the helix so far considered can only be the most important member of a series of coaxial helices of different radii; the non-phosphate parts of the molecule will lie on inner co-axial helices, and it can be shown that, whereas these will not appreciably influence the innermost maxima on the layer lines, they may have the effect of destroying or shifting both the equatorial maxima and the outer maxima on other layer lines.

Thus, if the structure is helical, we find that the phosphate groups or phosphorus atoms lie on a helix of diameter about 20 A., and the sugar and base groups must accordingly be turned inwards towards the helical axis.

Considerations of density show, however, that a cylindrical repeat unit of height 34 A. and diameter 20 A. must contain many more than ten nucleotides.

Since structure $B$ often exists in fibres with low water content, it seems that the density of the helical unit cannot differ greatly from that of dry sodium thymonucleate, 1·63 gm./cm.$^3$ [1,5], the water in fibres of high water-content being situated outside the structural unit. On this basis we find that a cylinder of radius 10 A. and height 34 A. would contain thirty-two nucleotides. However, there might possibly be some slight inter-penetration of the cylindrical units in the dry state making their effective radius rather less. It is therefore difficult to decide, on the basis of density measurements alone, whether one repeating unit contains ten nucleotides on each of two or on each of three co-axial molecules. (If the effective radius were 8 A. the cylinder would contain twenty nucleotides.) Two other arguments, however, make it highly probable that there are only two co-axial molecules.

First, a study of the Patterson function of structure $A$, using superposition methods, has indicated[6] that there are only two chains passing through a primitive unit cell in this structure. Since the $A \rightleftharpoons B$ transformation is readily reversible, it seems very unlikely that the molecules would be grouped in threes in structure $B$. Secondly, from measurements on the X-ray diagram of structure $B$ it can readily be shown that, whether the number of chains per unit is two or three, the chains are not equally spaced along the fibre axis. For example, three equally spaced chains would mean that the $n$th layer line depended on $J_{3n}$, and would lead to a helix of diameter about 60 A. This is many times larger than the primitive unit cell in structure $A$, and absurdly large in relation to the dimensions of nucleotides. Three unequally spaced chains, on the other hand, would be crystallographically non-equivalent, and this, again, seems unlikely. It therefore seems probable that there are only two co-axial molecules and that these are unequally spaced along the fibre axis.

Thus, while we do not attempt to offer a complete interpretation of the fibre-diagram of structure $B$, we may state the following conclusions. The structure is probably helical. The phosphate groups lie on the outside of the structural unit, on a helix of diameter about 20 A. The structural unit probably consists of two co-axial molecules which are not equally spaced along the fibre axis, their mutual displacement being such as to account for the variation of observed intensities of the innermost maxima on the layer lines; if one molecule is displaced from the other by about three-eighths of the fibre-axis period, this would account for the absence of the fourth layer line maxima and the weakness of the sixth. Thus our general ideas are not inconsistent with the model proposed by Watson and Crick in the preceding communication.

The conclusion that the phosphate groups lie on the outside of the structural unit has been reached previously by quite other reasoning[1]. Two principal lines of argument were invoked. The first derives from the work of Gulland and his collaborators[7], who showed that even in aqueous solution the —CO and —NH$_2$ groups of the bases are inaccessible and cannot be titrated, whereas the phosphate groups are fully accessible. The second is based on our own observations[1] on the way in which the structural units in structures $A$ and $B$ are progressively separated by an excess of water, the process being a continuous one which leads to the formation first of a gel and ultimately to a solution. The hygroscopic part of the molecule may be presumed to lie in the phosphate groups ($(C_2H_5O)_2PO_2Na$ and $(C_3H_7O)_2PO_2Na$ are highly hygroscopic[8]), and the simplest explanation of the above process is that these groups lie on the outside of the structural units. Moreover, the ready availability of the phosphate groups for interaction with proteins can most easily be explained in this way.

We are grateful to Prof. J. T. Randall for his interest and to Drs. F. H. C. Crick, A. R. Stokes and M. H. F. Wilkins for discussion. One of us (R. E. F.) acknowledges the award of a Turner and Newall Fellowship.

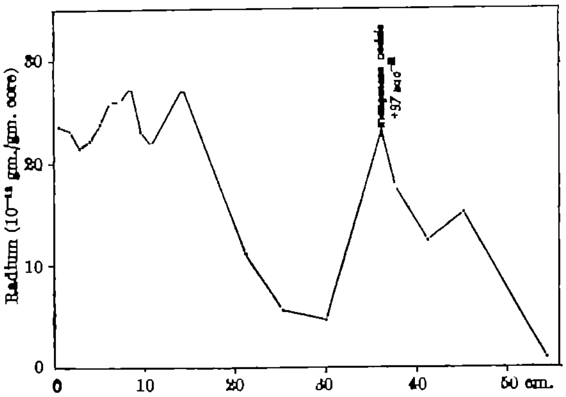
## Vertical Distribution of Radium in Deep-Sea Sediments

The surprisingly high content of radium in certain deep-sea sediments discovered nearly fifty years ago by J. Joly[1] remained unexplained until 1937, when H. Pettersson[2] suggested an ocean-wide precipitation of ionium from sea water on to the ocean bottom as its origin. Extensive radium measurements on deep-sea cores raised by the Swedish Deep-Sea Expedition carried out in this institute by Pettersson[3], T. Bernert[4] and me did not confirm the regular vertical distribution of radium reported by other workers[5]. An expected rise in radium content from moderate values in the uppermost surface layers to a maximum corresponding to a radioactive equilibrium between precipitated ionium and ionium-supported radium generally occurred; but the maximum was not followed by the theoretical exponential decline downwards governed by the rate of decay of ionium, to 50 per cent in 83,000 years, to 25 per cent in 166,000 years, etc. Instead, a number of secondary maxima of radium content separated by equally pronounced minima were observed (see graph), which could not well be explained as due to intervening changes in the rate of total sedimentation. Another explanation offered was that ionium and radium are not in radioactive equilibrium; that is, the assumption underlying the use of measurements of radium as indicating the concentration in the same layer of its mother element is unjustified.

Radium is well known for its migratory habits, leading to high concentrations of the element in manganese nodules. It was, therefore, decided to ask the assistance of a specialist on the photographic method—Dr. E. Picciotto, of the Centre for Nuclear Research in Brussels—to develop a method suitable for direct determinations of the content of ionium in the sediment. These attempts have met with success, as is seen from the following communication by Dr. E. Picciotto and Miss N. Isaac. So far, only a limited number of samples from Pacific red clay have been measured; but already the present results lend support to the conclusion that the greater part of the radium in the sediment is ionium-supported, and the migration of radium is proved.



Radium concentration in a red clay core from the Central Pacific Ocean at lat. N. 02° 23′, long. W. 173° 50′, depth of water 5,560 m. A manganese nodule with a concentration of 97·1 × $10^{-12}$ gm. radium/gm. sediment was found at a depth of 32 cm. in the sediment

However, interesting results can also be obtained from the radium measurements. Thus an integration of the total radium content in a sediment core down to levels ($L_0$) where practically all the ionium precipitated has had time to become disintegrated, so that generally only very small quantities of uranium-supported radium are present, permits a comparison between the excess radium in the upper sediment layers and the potential supply of radium derivable from the uranium in the superposed column of sea water. Although both figures are of the same order of magnitude, there appears to be a surplus of sediment radium over that to be expected from ionium precipitation by a factor of 1·5–3. This discrepancy, which evidently falls outside the limits of experimental error, may possibly be due to a considerably higher content of dissolved uranium in the ocean during late quaternary time than at present (namely, 1·3 × $10^{-6}$ gm. radium/litre[6]).

Having found through such an integration of the total radium content the corresponding value for the total ionium content in the sediment column, a theoretical value of the ionium content at $L_0$ can be calculated by assuming that the column $L_0$ is precipitated during a certain period of time (for example, 330,000 years = 4 half-periods of ionium). The time correlation is now varied until the calculated ionium content at $L_0$ is in correspondence with the measured radium content within limits of error. In this way we have found an average value for the rate of sedimentation during the period of time considered. The values thus found are of the order of 1 mm. in 1,000 years, in fair agreement with other methods of estimation. This method is, however, liable to errors, arising on one hand, as mentioned before, from a possible change in the rate of ionium sedimentation and, on the other, from the complication represented by the vertical migration of radium in the sediment.

A full report on these measurements and calculations will be published in the Reports of the Swedish Deep-Sea Expedition.

## Ionium Determination in Deep-Sea Sediments

Measurements carried out in the Oceanographical Institute, Göteborg, on the radium content in deep-sea cores by H. Pettersson, Traude Bernert, V. Kröll[1] *et al.* showed the vertical distribution of radium to be highly complicated. We were therefore asked to develop a method for direct measurement of the ionium content in samples of sediment from the Swedish Deep-Sea Expedition.

Uranium-$X_1$ (thorium-234) is added to a solution of the sample as radio-tracer for ionium (thorium-230).

The solution (0·5 $N$ hydrochloric acid) is passed through a column of ion exchanger ('Amberlite *IR*100'). Elution with 2 $N$ hydrochloric acid removes most of the cations, including uranium and radium. A second elution with 0·5 $M$ oxalic acid[2] releases the thorium isotopes together with polonium; the last-named element is removed by extraction with dithizone[3]. Oxalic acid is removed by calcination, and the nearly carrier-free thorium (ionium + uranium $X_1$) redissolved in the smallest possible volume of a complexing solution of citric buffer at $p$H 7[4]. The yield of ionium recovered is checked by counter-measurements of the β-activity of the uranium-$X_1$. The concentration of ionium is measured by the α-radiation detected with nuclear emulsion using the double-emulsion technique[5].

Assuming radioactive equilibrium between thorium and radio-thorium to prevail in the sample, the proportion of α-track 'stars' with five branches on the plates gives the concentration of thorium and permits the separation of thorium and ionium, since the latter gives only single α-tracks[6]. The method also permits the detection of possible residues of radium from the number of three- and four-branched stars. Measurements of the lengths of the tracks make it possible to detect impurities like uranium and polonium which give also single tracks.

The method was checked with a standard solution of ionium containing $10^{-11}$ gm. ionium/c.c., obtained by dissolving a sample of pitchblende and measuring the concentration of uranium in the solution. In this solution uranium was known to be in radioactive equilibrium with its descendants[7]. The concentration of ionium in this solution was of the same order as that in the uppermost layers of sediment examined.

The main difficulty lies in the preparation of uranium-$X_1$ of sufficient purity and in the elimination of radioactive contamination by the chemicals used and by the photographic emulsion.

The method enables us at present to measure a concentration of ionium between $10^{-9}$ and $10^{-10}$ gm./gm. to within 10 per cent, and to detect a concentration of $10^{-11}$ gm./gm. in a sample weighing 0·5 gm., a quantity which, by the use of microchemical methods, could be reduced to a few milligrams. An absolute quantity of ionium as low as $10^{-13}$ gm. contained in a volume of $10^{-3}$ c.c. can easily be measured by the photographic method.

Our main purpose has been to ascertain whether, in deep-sea sediments, there exists radioactive equilibrium between ionium and radium. For lack of a suitable method of determining ionium, it has hitherto not been possible to solve this problem. For this reason all conclusions regarding the vertical distribution in the sediment cores of ionium and subsequent inferences regarding the rate of sedimentation have so far had to be based on radium measurements and on the hypothesis that there is radioactive equilibrium between ionium and radium in the cores.

The samples we have worked on were taken from cores of deep-sea sediments raised in the Pacific Ocean by the Swedish Deep-Sea Expedition. Their radium content has been measured in Göteborg. The results so far obtained are too few to allow any general conclusions to be drawn, and the figures set out in the accompanying table should be considered as preliminary values, subject to revision after control measurements. With these reservations, they seem to lend support to the hypothesis of ionium precipitation, and they further indicate that the irregularities found in the radium curves may be due to a lack of radioactive equilibrium between ionium and radium.

| Sample No. | Core No. | Depth in sediment (cm.) | Radium ($10^{-12}$ gm./gm.) | Ionium ($10^{-10}$ gm./gm.) | $R = \frac{\lambda_{\text{Ra}} N_{\text{Ra}}}{\lambda_{\text{Io}} N_{\text{Io}}}$ |
|---|---|---|---|---|---|
| 4 | 83 | 3·5– 4·5 | 27·9 | 14 | 1 |
| 5 | 83 | 31·5–32·5 | 46·4 | 10 | 2·3 |
| 11 | 86*B* | 11·5–13 | 38 | 20 | 1 |
| 12 | 86*B* | 16·5–17·5 | 52 | 13 | 2 |
| 13 | 86*B* | 48 –49 | 19·1 | < 1 | > 1 |

We wish to thank the Oceanographical Institute of Göteborg, and in particular Prof. H. Pettersson, for support. We are indebted to Profs. F. G. Houtermans and G. P. S. Occhialini and to Dr. H. Rotschi for helpful suggestions, and to Mr. C. Waller (Ilford, Ltd.) for supplying specially purified emulsion.

## An Interferometer Microscope for the Accurate Measurement of Optical Thickness

The methods developed by Barer[1] and Davies and Wilkins[2] for the measurement of the dry weights of cells involve the accurate measurement of the optical thickness of the cell at a number of points on its surface. In many cases, the optical thickness is quite a small fraction of a wave-length, so the measurement must be made with considerable accuracy; furthermore, in the case of a living cell, speed of measurement is essential.

In order to fulfil these conditions, a new type of interferometer microscope has been designed. The basic arrangement of the microscope is similar to that of Lebedeff[3], in which the specimen is enclosed between two birefringent plates together with a suitably oriented half-wave plate. Lebedeff's microscope, however, enabled only very thin plates to be used at high powers, resulting in a doubling of the image. To overcome this difficulty, a glass hemisphere is cemented to the upper plate to increase the working distance of the objective[4]. In this way, plates 5 mm. thick can be used with a 4-mm. objective, and the second image becomes so far out of focus that it disappears.

The system gives an image of the light source and an image of the source with the object superimposed, coincident and polarized mutually at right-angles. If viewed through an analyser at 45° to each plane of polarization, the two images interfere and the object is revealed by normal interference contrast. In order to effect the measurement, further modifications are introduced. A birefringent quarter-wave plate is placed above the objective, suitably oriented so that the image and reference beams are circularly polarized in opposite senses thereby. These two beams then combine to form a single plane-polarized beam, with an orientation of polarization depending on the phase differences between the two beams. The plane of polarization may then be rotated by a rotatable half-wave plate with suitable scale. The phase-difference may be measured by rotating the plane of polarization to a fixed position and reading off from the scale the angle through which it has been turned.

In order to determine accurately when the plane of polarization has a given direction, a half-wave plate consisting of a sheet of 'Cellophane' is placed in the focal plane of the eyepiece. A system of small squares, arranged in chequer-board formation, is cut out of the half-wave plate, and the analyser is fixed, making an angle of 45° with the principal directions of the half-wave plate. Under these conditions, there is an intensity contrast between the cut-out squares and the rest of the field unless the plane of polarization is parallel to one of the principal directions of the half-wave plate. Hence, an accurate setting for the orientation of the plane of polarization is possible by adjusting for disappearance of each small square in turn.

Using mercury green light, it has been found possible under good conditions to repeat settings within ± 0·25°, which corresponds to ± 0·003 wave-lengths, as a complete rotation corresponds to four wave-lengths. The chequer-board formation of the squares facilitates the averaging of optical thickness over the cell.

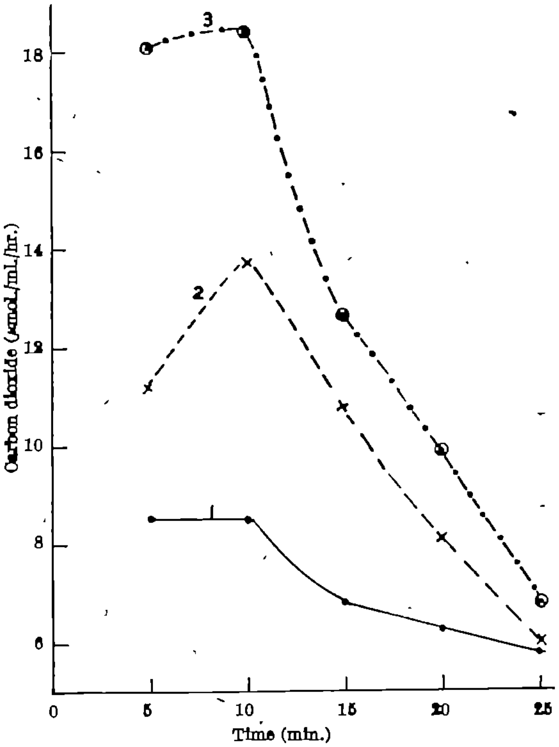
## Hydrolysis of Anhydrides by Esterases

IN recent investigations[1] the idea was expressed that tetraethyl pyrophosphate and related inhibitors of esterases are enzymatically split into a positive phosphonium ion and a negative residue, the former attaching itself to a nucleophilic group in the active surface of the enzyme. The irreversible combination of organic phosphates with esterases is thus analogous to the reaction of esters as substrates: here the acylinium ion is attached reversibly to the enzyme. The ease with which anhydride bonds are split was used for explaining the superiority of this type of inhibitor over trialkyl phosphates. However, since esters are the natural substrates of esterases, it can be expected that both types of compounds, esters as well as anhydrides, are attacked by the same enzyme, the latter at a faster rate. This was borne out by the following experiments.

(1) Carboxylic acid anhydrides are split both by acetylcholine esterase and by liver esterase. This cannot be demonstrated 'directly' by adding the substrate to the buffered enzyme solution, since spontaneous hydrolysis of such anhydrides in dilute aqueous media is very rapid. We have therefore developed a 'two-phase' technique by placing the substrate, dissolved in toluene, into the side bulb of a Warburg vessel. Upon adding the organic solution to the main vessel, an equilibrium between the two layers is established, thus supplying the aqueous phase continuously with small amounts of substrate. The accompanying graph shows that liver esterase increases the hydrolysis of propionic anhydride by about 100 per cent and the choline esterase by about 60 per cent.



Enzymatic hydrolysis of propionic anhydride. The anhydride was dissolved in toluene, 1 : 100 ; 0·2 ml. was added to the side bulb of each Warburg vessel. The main vessel contained 2·9 ml. of (1) bicarbonate buffer (control); (2) acetylcholine esterase, 1 : 2,500 (this preparation from electric organ, when diluted 1 : 40,000, hydrolysed 6 µmol./ml./hr., when acetylcholine, $3\cdot3 \times 10^{-3}$ *M*, was used as standard substrate); (3) liver esterase, 1 : 60 (this enzyme from dog's liver, at a dilution of 1 : 100, produced 5·2 µmol. carbon dioxide/ml./hr., when diacetin, $4\cdot1 \times 10^{-2}$ *M*, was used as standard substrate). Note that 2 mol. carbon dioxide is equivalent to 1 mol. propionic anhydride

(2) By using the dilution technique, we have been able to demonstrate that triethyl phosphate is an irreversible inhibitor of acetylcholine esterase, but the concentrations required for a given degree of inhibition are 100–200 times higher than with tetraethyl pyrophosphate (see table).

(3) On the basis of these results, it can be expected that a mixed phosphoric – carboxylic anhydride will also be split by esterases, but the direction of the

IRREVERSIBLE INHIBITION OF ACETYLCHOLINE ESTERASE BY TRIETHYL PHOSPHATE

The enzyme, 0·2 ml., was incubated with 1·0 ml. of a $7\cdot2 \times 10^{-4}$ *M* solution of the inhibitor in bicarbonate buffer (0·1 *M*). After 30 min. the mixture was diluted 250 times and its hydrolytic activity measured by the Warburg method. Final dilution of the enzyme 1 : 1,500 ; final concentration of the inhibitor $2\cdot4 \times 10^{-6}$ *M*. A control was run by diluting the inhibitor first and then incubating with the enzyme. The substrate was acetylcholine, $3\cdot3 \times 10^{-3}$ *M*

| | Activity (µmol hydrolysed/ml./hr.) | % Inhibition |
|---|---|---|
| 1. Enzyme alone, 1 : 1,500 | 5·5 | |
| 2. Enzyme + diluted inhibitor | 3·6 | 35 |
| 3. Enzyme + concentrated inhibitor | nil | 100 |

hydrolysis is not predictable. If the C—O bond is broken, the mixed anhydride will serve as substrate, whereas attack at the P—O bond will lead to inhibition. We have found that dibenzyl acetyl phosphate is an irreversible inhibitor of choline esterase. Since this anhydride is split by water very rapidly, the inhibitory effect was demonstrated by adding 0·01 ml. of the undiluted inhibitor to 0·1 ml. of the buffered enzyme. After 5 min. at room temperature, the mixture was diluted thirty times and the remaining activity of the enzyme compared with an untreated control. Under these conditions our derivative of acetyl phosphate produced complete inactivation of the esterase, whereas the control hydrolysed 6 µmol. of acetylcholine/ml./hr. Treatment of the enzyme with a 1 : 30 dilution of the anhydride in buffer gave no inhibition because of the rapid spontaneous hydrolysis of the inhibitor.

A detailed account of these experiments will be published elsewhere. We wish to thank Mr. J. Blank for the preparation of dibenzyl acetyl phosphate.

## Enzymatic Transoximation

IT has been recently shown[1] that oximes are enzymatically converted into amino-compounds. I have now demonstrated an enzyme which catalyses the transoximation.

The enzyme was prepared from silkworms. 2 gm. of digestive organ-free tissues of fifth instar larvæ was ground and centrifuged twice after adding water. The residue was mixed with 3 ml. of 0·01 *M* pyruvic acid oxime, 3 ml. of 0·01 *M* acetaldehyde and 3 ml. of 0·01 *M* acetone and then diluted with water or 0·015 *M* buffer to 30 ml. The mixture was put in a 100-ml. Erlenmeyer flask, covered with toluol and kept at 35° C. for 15 hr. After reaction, the mixture was distilled *in vacuo*, and the total amount of acetaldoxime and acetoxime in the distillate was determined colorimetrically. In the control, the enzyme preparation was used after heating at 100° C. for 10 min.

Experiments indicated that the enzymatic activity was reduced to half by heating at 60° C. for 10 min. The optimum *p*H of enzyme action was about 5·6 and the optimum temperature 37° C. Under the experimental conditions described above, about 10 µgm. of oxime-nitrogen was transferred, and no free hydroxylamine or nitrous acid was detected in the reaction mixture. I suggest the name 'transoximase' for the enzyme.

## Active Absorption of Glucose from the Intestine

GLUCOSE disappeared rapidly from the lumen of an isolated loop of rat intestine, immersed in tyrode at 37° C. and aerated by a mixture of oxygen and 5 per cent carbon dioxide. This occurred even when the solutions (tyrode containing 200–800 mgm. per cent glucose) within the loop and surrounding the loop were identical, so that no concentration gradient of glucose existed between the inner and outer solution. The rate of uptake of glucose, during the first 15–30 min., was of the same order of magnitude as that found during resorption *in vivo* from similar solutions. With other sugars, the uptake was related to their rate of resorption in the intact animal. Phlorrhizin inhibited absorption of glucose *in vitro* as well as *in vivo*. It therefore seemed probable that we were dealing with 'active absorption' when using such a preparation.

Though glucose disappeared from the lumen, glucose as such was not transferred across the intestinal wall, and the outer fluid showed no increased glucose content. When a similar experiment was carried out with radioactive glucose in the inner solution, a radioactive substance appeared in the outer fluid ; 30–60 per cent of the radioactivity which had disappeared from the inner solution could thus be recovered. The recovery increased with time of incubation up to one hour. The radioactive substance is not identical with glucose ; it is non-reducing and is not fermented by baker's yeast. It is not converted into glucose by acid hydrolysis, and so far has not been identified with any known intermediate of glucose dissimilation. Much of the glucose which had disappeared was retained in the lumen as a substance having characteristics similar to those of the substance appearing in the outer solution.

It was of interest to ascertain whether the conversion of glucose to a metabolite, in its passage across the intestinal wall, is a general phenomenon or is associated with the conditions prevailing in these *in vitro* experiments. It is generally believed that glucose absorbed from low concentrations (that is, during active absorption) is transferred to the portal vein as glucose. However, the evidence provided by the literature was found to be both scanty and unconvincing. Most papers dealt only with the fate of glucose in the intestinal lumen, but had very little to say about its appearance on the other side of the intestinal barrier.

In order to test this, glucose concentrations in the portal vein and in the artery were compared during resorption of glucose from a 400 mgm. per cent solution. In a representative experiment, 18 mgm. of glucose disappeared during 12 min. With a blood flow of 4 ml./min. (calculated from data of Birnie and Grayson[1]), the glucose concentration in the vena porta should have exceeded that in the artery by 37 mgm. per cent, if it was glucose which was transported by the vena porta. However, the glucose concentration in the vena porta was found to be even lower than in the arterial blood.

Further proof that no additional glucose as such appears in the vena porta during glucose absorption was then sought by perfusing the intestine *in situ* with blood of known composition. When a 400 mgm. per cent glucose solution was introduced into the loop of a perfused intestine, 17·2 mgm. glucose disappeared in 12 min. but no additional glucose could be found in the perfusion fluid. With radioactive glucose in the lumen, a substance could be demonstrated in the perfusion fluid similar to that found in the outer fluid in our *in vitro* experiments (making up 35 per cent of the glucose which disappeared).

It might be claimed that with low glucose concentrations a considerable part of the glucose is utilized by the intestine. However, measurement of oxygen consumption, both *in vivo* and *in vitro*, revealed that less than 10 per cent of the glucose taken up is burned to carbon dioxide. It seems that most of the absorbed glucose is transferred in the form of a metabolite through the portal system and is reconverted into glucose in some other organ, presumably in the liver. The active translocation of glucose from the intestinal lumen into the blood stream would thus involve the participation of both the intestine and the liver.

Experiments are being conducted to test this assumption.

## Distribution of Substance *P* in the Central and Peripheral Nervous System

Substance *P* is a biologically active polypeptide found in extracts of brain and intestine[1,2]. It causes a transient fall of the blood pressure and stimulation of smooth muscle even in the presence of atropine and antihistamine drugs. Purified preparations exert biological effects even in concentrations of 1 μgm. per ml. The present communication deals with its distribution in the nervous system.

Extracts, obtained from the dog, were prepared by boiling the tissue in water at *p*H 4, and tested on the isolated guinea pig ileum in the presence of 1 : 2,500,000 atropine and 1 : 2,500,000 of antihistamine (Lergitin). The activity of the extracts was compared to a standard of a partially purified preparation of substance *P*, obtained from horse intestine by precipitation with ammonium sulphate[3]. The specificity of the active factor was proved by precipitation in some cases with ammonium sulphate and inactivation with chymotrypsin.

(1) *Central nervous system.* The highest values were found in the grey matter, which agrees with the results of Euler and Gaddum[1]. This may suggest that the substance is concentrated in the cell bodies. In the cerebellum, however, with its high content of cells, the amount of substance *P* is low. Its activity of the different parts of the central nervous system runs almost parallel to the acetylcholine content[4], except in the extracts of the hypothalamus, which show the highest concentration of substance *P* in the brain.

Table 1. Distribution of Substance *P* in the Central Nervous System

| Tissue | Units of subst. *P*/gm. tissue |
|---|---|
| Medulla spinalis | 35 |
| Pons | 45 |
| Cerebellum | 15 |
| Tegmentum | 75 |
| Hypothalamus | 180 |
| Tractus opticus | 50 |
| Thalamus | 85 |
| Basal ganglia | 130 |
| Corpus callosum | 8 |
| Bulbus et tractus olfactorius | 9 |
| Hemisphere | 20 |
| Plexus choroideus | 1 |

(2) *Peripheral nervous system.* Substance *P* activity is found in extracts of all kind of nerves and ganglia. The values obtained, however, are generally lower than those found in the central nervous system. The dorsal roots, the preganglionic sympathetic fibres and the vagus seem to be especially rich in substance *P*, whereas motor nerves such as the phrenic have a low content.

Table 2. Distribution of Substance *P* in the Peripheral Nervous System

| Tissue | Units of subst. *P*/gm. tissue |

## A New Synthesis of some Derivatives of 4,4′-Stilbenediol

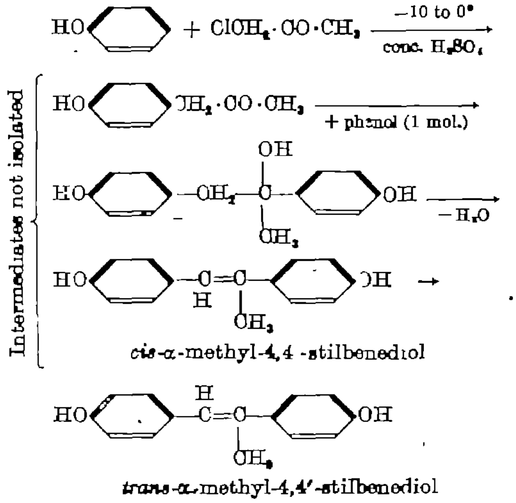
Syntheses of α-alkyl- or α,α′-dialkyl-4,4′-stilbenediols and of their derivatives, several of which exhibit remarkable œstrogenic activity, have so far mostly been by demethylation of the corresponding dimethyl ethers, and have invariably involved several stages[1,2]. A direct synthesis in one step, of *trans*-α-methyl-4,4′-stilbenediol (and some of its dialkyl ethers) from phenol (or its corresponding ether) and chloroacetone, has now been accomplished.

The condensation of chloroacetone with phenol in presence of concentrated hydrochloric acid at 100° has been reported to yield 2,2,3-tris(*p*-hydroxyphenyl)propane[3]. We have found that in presence of concentrated sulphuric acid at − 10° to 0°, the above reactants give a nearly 75 per cent yield of *trans*-α-methyl-4,4′-stilbenediol (earlier synthesized by Dodds and his collaborators[2]) (melting point 183–184°). The melting points of some ethers and esters of this substance, prepared by the usual methods, are shown in the accompanying table.

| Ether or ester of *trans*-α-methyl-4,4′-stilbenediol | Melting point |
|---|---|
| Dimethyl ether* | 124° |
| Diethyl ether | 105–107° |
| Dipropyl ether | 107–108° |
| Diallyl ether | 94–95° |
| Diacetate* | 124° |
| Dipropionate | 107–108° |

* Previously described by Dodds *et al.* (ref 2)

The above condensation, yielding *trans*-α-methyl-4,4′-stilbenediol, probably proceeds according to the following route :



The extreme activity of the chlorine atom of the chloroacetone molecule by reason of its vicinity to the carbonyl group, and the reactivity of the hydrogen atom *para* to the hydroxyl group in the phenol molecule, suggested a Friedel–Crafts type of reaction as the first step.

The above reaction would appear to be generally applicable to ketones of the formula $R$—CO—CHCl$R'$, where $R$ is a lower alkyl radical and $R'$ is hydrogen or a lower alkyl radical, and any simple aromatic compound containing a suitably activated available nuclear hydrogen atom. Thus, the dimethyl and diethyl ethers of *trans*-α-methyl-4,4′-stilbenediol have also been obtained, in very good yields, by condensing chloroacetone with anisole and phenetole respectively in presence of concentrated sulphuric acid.

In these reactions, the *cis* compounds seem to be formed first, and are probably converted to their *trans* isomers on heating in solution in solvents like alcohol or aqueous alcohol; thus in the condensation of anisole and phenetole with chloroacetone, the crude semi-solid reaction product, after treatment with water at 0°, yielded only a viscous oil (presumably the *cis* compound) when recrystallization from alcohol was attempted; but when an alcoholic solution of this oily product was refluxed for a few hours and then cooled, the *trans* form of the corresponding dialkyl ether of α-methyl-4,4′-stilbenediol crystallized out.

A fuller account will be published in due course. We are grateful to several colleagues for the benefit of discussion. One of us (P. M. B.) is indebted to the National Institute of Sciences of India for the award of a research fellowship.

## Carbohydrate Metabolism in Protozoa and Metal-binding Substances

THE effect of cyanide on fermentation processes of living cells, which is on the whole much smaller than that on respiration, has been interpreted in the past as due to the interception by cyanide of intermediary products of fermentation, rather than to complex formation with heavy-metal catalysts; as pointed out again only recently, "no enzyme of fermentation is known to require the addition of a heavy metal except the aldolase of yeast"[1]. That not all living cells conform with this view has already been indicated by our previous work on the metabolism of certain Protozoa, and in particular by the finding that the anaerobic fermentation of glucose by the flagellate *Trypanosoma lewisi* is inhibited 50 per cent by 0·007 $M$ cyanide and also by such metal-binding substances as 2 : 2′-dipyridyl and 8-hydroxyquinoline[2]; on the other hand, the same metal-binding substances have been shown to have a small but definite stimulating effect on intracellular glycogen fermentation in the ciliate *Tetrahymena pyriformis*[3]. These effects have now been investigated further.

Under aerobic conditions at 37° C., washed suspensions of *Trypanosoma lewisi* in the absence of extracellular nutrient respire with a $q_{O_2}$ of about 40 and a respiratory quotient of 0·80 for a period of 1–2 hr. During this time, the flagellate shows a small degree of motility; but, within 5–10 min. of the addition of glucose, motility increases considerably, and the $q_{O_2}$ rises to about 600, with a respiratory quotient of almost unity. When, however, the flagellate is incubated for longer periods of time in the absence of substrate, the endogenous respiration and motility gradually fall, and the ability to respond to added glucose is lost, death of the trypanosomes soon taking place. The respiration of the trypanosome in the presence of glucose is not markedly influenced by 0·001 $M$ 2 : 2′-dipyridyl, there being only a 10 per cent inhibition of respiration and scarcely any effect on motility over the first hour, with a somewhat greater inhibition of respiration and motility after 2–3 hr.; a similar effect is produced by 8-hydroxyquinoline. If, however, substrate-free trypanosomes are incubated with 0·0003 $M$ 2 : 2′-dipyridyl, their ability to respond to added glucose is quickly lost; after 30 min. incubation, the recovery of respiration and motility is slow and incomplete, while after 90 min. the trypanosomes become immotile, and will not respond to added glucose, although, in the absence of inhibitor, normal motility is restored within 15 min. of the addition of glucose.

Under anaerobic conditions, the effects of 2 : 2′-dipyridyl and 8-hydroxyquinoline on carbon dioxide production by the trypanosomes in the presence of glucose and a carbon dioxide – bicarbonate buffer are much greater. When added to actively fermenting trypanosomes, 0·0003 $M$ 2 : 2′-dipyridyl reduces carbon dioxide output by 65–75 per cent over a period of 45 min., metabolism and motility having ceased completely by this time. On addition of the reducer sodium dithionite to such a suspension, a pale pink colour is produced, indicating the formation of a ferrous iron–dipyridyl complex. 0·0001 $M$ 2 : 2′-Dipyridyl is almost as effective, while 8-hydroxyquinoline produces a slightly quicker inhibition. These metal-binding substances are more effective when added to substrate-free trypanosomes at the same time as glucose, rather than to actively fermenting cells. The effect of 2 : 2′-dipyridyl on fermentation is irreversible.

During studies of the intermediary metabolism of *Trypanosoma lewisi*, using homogenates prepared by shaking an aqueous suspension of cells with glass beads, the effect of 2 : 2′-dipyridyl on aldolase activity was investigated. The disappearance of fructose-1 : 6-diphosphate and the production of alkali-labile phosphate were followed in a system containing cell homogenate, incubated at 37° C. in the presence and in the absence of 0·06 *M* potassium cyanide. At pH 7·0 or 6·4 in carbon dioxide – bicarbonate or acetate – veronal buffers, the reaction was scarcely affected by 0·001 *M* 2 : 2′-dipyridyl, while 0·005 *M* 2 : 2′-dipyridyl produced only a 33 per cent inhibition of aldolase activity. This result is quantitatively similar to that obtained with the ciliate *Tetrahymena pyriformis* (GL), an organism the respiration of which is insensitive to 2 : 2′-dipyridyl, and the fermentation of which is slightly stimulated by this substance[3].

It has recently been reported that aldolase activity in homogenates of the closely related flagellate *Trypanosoma cruzi* is not affected by 2 : 2′-dipyridyl; but no mention was made of the effect of this substance on the metabolism of intact cells[4]. The present results with *Trypanosoma lewisi* suggest that, although aldolase activity is probably independent of the presence of a heavy metal ion, such an ion, very probably ferrous iron, is involved at some stage in the glucose fermentation process. Inhibitions produced by 2 · 2′-dipyridyl are not prevented by the presence of hæmoglobin, and neither respiration nor fermentation is influenced by 0·0003 *M* 4 : 4′-dipyridyl; this indicates that if ferrous iron participates in fermentation, it is involved as the free ion, and not bound as a hæm compound. Under aerobic conditions, iron would be mainly in the ferric condition, and therefore not removed by 2 : 2′-dipyridyl; but under anaerobic conditions it would be reduced to the ferrous state, and could be quickly removed by chelation with 2 : 2′-dipyridyl.

I should like to thank Prof. D. Keilin and Dr. T. Mann for helpful discussions during the course of this work, and the Medical Research Council for a research studentship.

## Nature of Cold Agglutinin Linkage

If sera containing auto-agglutinins ('non-specific cold agglutinins') are repeatedly absorbed in the cold with *O* cells, one of three results may be obtained: (1) activity against *A* and *B* cells may cease; this is the only result reported by numerous earlier workers; (2) activity against *A* and *B* cells may persist to a greater or lesser extent; subsequent absorption with *A* cells may leave some residual anti-*B* activity[1]; (3) activity against *A* and *B* cells may be enhanced[2].

These results support the view that auto-agglutinins are 'non-specific', because they consist of multiple specific components which may exhibit a varying degree of agglutinin linkage[3]. The multiple specific components may be anti-*O* (or *H*), anti-*A*, anti-*B*, and possibly also anti-$A_1$, anti-*M*, anti-*N*, anti-*P*, etc. The combination of non-specific cold agglutinins with an anti-*M* 'iso-agglutinin' reported by Macfarlane[7] may have been auto-agglutinins containing a relatively powerful anti-*M* component. It is not surprising that Henningsen[5], "by using a sensitive technique", could demonstrate anti-*P* antibodies in most *P*-negative sera. Some of these agglutinin components may figure in the lists of numerous antibodies occasionally detected in a single serum[9].

The enhancement of anti-*A* and anti-*B* activity in some sera after absorption with *O* cells may be of importance in providing a pointer to the structure of auto-agglutinins. The cold auto-agglutinins present in almost all sera are believed to be of heterogenetic bacterial origin[8]. These stimuli are continuous, minimal, and of varying antigenicity. It is not inconceivable that certain antibody receptors are first formed and followed by other more superficial receptors. Suppose anti-*A* and anti-*B* receptors are laid down in the beginning, and later a relatively large number of anti-*O* receptors are laid down. It would then be easy to visualize how the absorption of the anti-*O* receptors would unmask the anti-*A* or anti-*B* receptors.

This view is not inconsistent with Dodd's concept[4] of iso-agglutinin linkage, and might also account for the phenomenon of Hooker and Anderson[6]. These workers noted that, by absorbing certain immune rabbit anti-*B* sera with *O* cells, the sera developed the ability to act on *A* cells as well.

It is considered that this concept may also be of value in the elucidation of the true structure of antibodies in general.

## Short-Term Carbon Dioxide Fixation in Mouse Liver

In a previous report[1], there were presented findings which were unexpected if the entire polycarboxylic acid cycle were involved in carbon dioxide fixation by animals. At 5 and 15 min. after the injection of radioactive sodium bicarbonate ($NaH^{14}CO_3$) (obtained as $Ba^{14}CO_3$ from the Atomic Energy Commission, Oak Ridge, Tennessee) there appeared to be a more direct path of carbon to succinate than that previously postulated. In addition, the labelling in such acids as α-ketoglutarate, citrate and aconitate was not measurable. It was thought desirable to examine the path of carbon dioxide employing paper chromatography, because by this technique compounds retained by the silica gel (used in previous studies) which escaped examination would become detectable.

The active bicarbonate was injected intraperitoneally into mice weighing 20 gm. and the animals were sacrificed 3 min. later. Extracts were prepared by homogenizing the liver in 80 per cent ethanol, centrifuging and removing the supernatant. This solution was reduced in volume to 0·7 ml. 25 µl. was added in 1-µl. quantities to Whatman paper (No. 1, 14 in. × 16 in.) and chromatographed in glass cylinders. Phenol–water (4–1 v/v) and butanol – propionic acid – water[2] were the developing solvents used for the two-dimensional ascending chromatography[3]. After development, the paper was air-dried at 20° C. and placed over X-ray film for two weeks in a dark room.

In order to identify the darkened spots the solutes were chemically located on the paper, and thereby the radioactive spots on the film were described by super-position. Amino-acids were detected by the use of ninhydrin, and, when each amino-acid having activity was rechromatographed with the corresponding inert amino-acid, a single spot was obtained for the mixture in each case. Urea was identified with the phenol-chlorox reagent[3] and it was rechromatographed similarly. Since the quantities of organic acids were too small to be detected with the use of $p$H indicators, their distributions between 0·1 $N$ hydrochloric acid in ether were studied, following extraction from the paper. Naturally occurring malic, oxalacetic and succinic acids showed distribution coefficients of 0·17, 0·045 and 0 012 respectively, as compared to 0·16, 0·043 and 0 15 for the authentic corresponding acids. Glucose was identified by the benzidine–acetic acid–ethanol reagent[4], and its position was confirmed by rechromatographing with reagent glucose. Since the distribution coefficients of succinate deviated by more than 10 per cent from the reagent value, the liver extract was chromatographed on silica gel[5], and the chromatographic zone assigned to succinate was assayed for activity.

Our results show, as previously, that the labelling in aconitic, fumaric and α-ketoglutaric acids is not detectable. The extent of incorporation of the tracer into succinate, oxalacetate and malate indicates, at least, that the total activity of these acids is greater than that of the other acids in the cycle. The relative concentrations[6] of these acids alone could not account for these results. This labelling of succinate and the absence of labelling of the other acids of the polycarboxylic acid cycle would seem to indicate that the cycle is not involved in a way that would be expected. Moreover, the lack of detectable activity in fumarate, the chemical concentration of which is greater than succinate[6], rules out the possibility that the oxalacetate served as a precursor of succinate by way of a reversed dicarboxylic acid cycle. The presence of the label to a small degree in glutamic acid but its absence in α-ketoglutarate can be explained by the higher concentration of the former in the liver. The most active compounds formed were glucose, urea, succinate, oxalacetate and malate. The appearance of the label in a large number of compounds suggests that the results for these short-term periods of carbon dioxide fixation *in vivo* cannot be accounted for by non-equilibration, and that the incorporation of the carbon-14 dioxide proceeds rapidly.

This investigation was supported in part by a grant from the Damon Runyon Memorial Fund.

## Influence of Ovarian Hormones on Uterine Infection

Willett *et al.*[1] and Brook and Rowson[2] reported that pyometra frequently followed the insemination of cows when in the luteal phase of the œstrous cycle; but no definite reason for this occurrence was forthcoming. The present communication gives the results of experiments carried out on cows at various stages of the œstrous cycle and also on cows that had been ovariectomized.

A standard technique was adopted throughout the experiments, whereby the cervices of all animals were swabbed in the mid-cervical region for bacteriological culture using a sterile sheathed swab and sterile speculum. Immediately afterwards, the cows were inseminated by passing a normal sterile insemination pipette through the cervix and into the body of the uterus where the inseminated material was deposited. The material injected was either buffered semen known to be infected or cultures of *Corynebacterium pyogenes* isolated from bull semen. Two days after insemination, all cows were slaughtered and the reproductive organs removed for bacteriological examination.

The experiments were divided into three parts: (1) bacteriological examination of the uterus both before and after insemination with infected material in the luteal and follicular phases of the œstrous cycle; (2) bacteriological examination of the uterus after insemination following the injection of stilbœstrol or progesterone into ovariectomized cows; (3) studies of the effect on bacteria of penicillin, streptomycin and sulphanilamide added to infected material inseminated during the luteal phase.

The work proved quite conclusively that when infected material was injected into the uterus during the luteal phase of the cycle, pyometritis invariably resulted. On the other hand, all cows which were inseminated during œstrus had sterile uteri on slaughter two days later.

It was found that these phenomena could readily be reproduced in ovariectomized cows by the administration either of progesterone or stilbœstrol. In some cases pure cultures of *Corynebacterium pyogenes* were used instead of infected semen; yet in the animals given stilbœstrol, the uteri were sterile two days later. In ovariectomized control cows not receiving exogenous hormones, a sterile pyometritis resulted.

The results on control animals indicated that this phenomenon is due more to a stimulating effect of progesterone rather than to an inhibiting effect of œstrogen, but that the latter, in sufficient doses, will tend to overcome the effect of the former.

In the third experiment it was found that although the antibiotics and sulphanilamide prevented severe pyometritis and gave sterile uteri at slaughter, a certain amount of cellular debris had collected in the uterus giving the appearance of a mild pyometritis.

These results are of particular interest because they indicate quite clearly the tremendous bactericidal properties of the uterus during œstrus. They may explain why cows sometimes recover spontaneously from *Vibrio fœtus* and trichomonad infections after a number of heat periods without re-infective coitus. They may also indicate why the bull does not recover spontaneously from infections of *Vibrio fœtus* and trichomoniasis, for the bull normally secretes testosterone from the testis, which has a similar effect to progesterone. If testosterone has a similar effect in the bull to progesterone in the cow, then continuous testosterone production by the testis would make spontaneous recovery from genital infection of the bull unlikely. Experiments now planned are designed to show whether or not it is possible to treat such infected bulls successfully with exogenous œstrogen.

The possibility of controlling by the use of œstrogens the infections which follow abortion or parturition in the human might also be worth investigation.

The experiments described here form part of the work being carried out by the Agricultural Research Council Unit of Animal Reproduction at Cambridge, and we wish to thank the Ministry of Food for the loan of the cows, Dr. John Hammond for advice and encouragement, and the staff of the Animal Research Station and Public Health Laboratory for their continuous help.

## Mucin Secretion in the Ewe's Oviduct

As part of a study on the reproductive organs of the female sheep, histological and histochemical investigations were undertaken on the oviducts of thirty ewes to determine whether the epithelial cells exhibited secretory activity and, if so, to establish the nature of the secretion.

In this investigation it was found that material positive to Schiff's periodic acid[1] was secreted by the non-ciliated epithelial cells during pro-œstrus and œstrus. In pro-œstrus the secretory globules extended on each side of the nucleus towards the proximal part of the cell, whereas in œstrus the globules were confined to the distal portion. Secretion was found in the lumen during œstrus and metœstrus but not during di-œstrus or pro-œstrus. Positive reaction was obtained after treatment with saliva, showing that the secreted material was not glycogen. This is at variance with the findings of earlier workers using the human oviduct. A positive reaction was obtained also after hyaluronidase, which excludes the presence of hyaluronic acid. The material did not exhibit metachromasia on staining with toluidin blue or celestin blue; and accordingly it is not an acid mucopolysaccharide. Again, a positive reaction with the periodic acid test was obtained after the methanol and chloroform test[2], thus eliminating the presence of glycolipid. In the light of these staining reactions, it can be assumed that the material was mucoprotein or "neutral mucopolysaccharide"[3].

The secretory cells were most numerous in the ampulla, and therefore the secretion was most abundant in this situation. The number of secretory cells was greatly reduced in the isthmus, and none was present in the vicinity of the oviduct–uterine junction.

A detailed account of this work will be published elsewhere.

## Paper Chromatography of Œstrogens

The Burton, Zaffaroni and Keutman[1] method for the paper chromatographic analysis of the adrenal cortical steroids has been found to be suitable for the non-steroid œstrogens of the hexœstrol series (hexœstrol, stilbœstrol, dienœstrol, trienœstrol[3]) and ethinyl œstradiol. It can also be used for the natural œstrogens (private communication from H. Grundy). Development is carried out using the toluene – propylene glycol system, and the detecting reagent, a mixture of 1 per cent ferric chloride and 1 per cent potassium ferricyanide as used by Barton, Evans and Gardner[2], gave a blue spot with less than 2 µgm./sq. cm. of the run synthetic œstrogen. In addition, stilbœstrol, dienœstrol, trienœstrol but not hexœstrol gave a strong absorption at 2300 A., and dienœstrol a blue and trienœstrol a green fluorescence at 3600 A.

The presence of trienœstrol in the urine, fæces, but not blood extracts of animals injected with the œstrogen, has been demonstrated using this paper chromatographic method, and the amount estimated by the modified Allen Doisy[4] bioassay technique. Trienœstrol, when added to blood, could be easily detected. Similarly, in animals injected with ethinyl œstradiol, the unchanged œstrogen, but no œstrone or β-œstradiol, could be detected in the fæces.

This method of chromatography is, however, not very suitable for detecting œstriol in urine or fæces, as other very slow-moving chromogenic compounds interfere. A fuller account of these results as well as those obtained from the injection of other œstrogens will be published elsewhere.

ŒSTROGENS CHROMATOGRAPHED IN TOLUENE – PROPYLENE GLYCOL IN ORDER OF DECREASING MOVEMENT

| Compounds | Movement ratios |
|---|---|
| Œstrone—<br>11-Deoxycorticosterone | 0·40 |
| Ethinyl œstradiol—<br>11-Deoxy-17-hydroxycorticosterone | 0·73 |
| 17-β-Œstradiol —<br>11-Deoxy-17-hydroxycorticosterone | 0·65 |
| Hexœstrol —<br>11-Dehydro-17-hydroxycorticosterone | 1·1 |
| Stilbœstrol —<br>11-Dehydro-17-hydroxycorticosterone | |
| Dienœstrol —<br>11-Dehydro-17-hydroxycorticosterone | |
| Trienœstrol —<br>11-Dehydro-17-hydroxycorticosterone | 0·81 |
| Œstriol | Extremely slow |

I wish to thank Prof. E. C. Dodds for having made this work possible, and Mr. W. Lawson for his interest in the work and for supplying the œstrogens.

## Iodination of Keratin

FOR the purposes of another investigation, it has been found necessary to devise a method of iodinating the tyrosine side-chains of keratin exclusively and completely. With aqueous solutions of iodine (0·1 *N*), no more than 75 per cent of the tyrosine of wool was iodinated under the best conditions used (64 hr. at 22·2° C. and *p*H 9). It has, however, been found that almost complete conversion into 3 · 5-di-iodo-tyrosine is obtained by treating wool (0·421 gm.) with a 0·78 *N* solution of iodine in absolute alcohol (50 c.c.) for 72 hr. at 25° C.

The tyrosine contents of the treated and untreated wools were determined by the method of Block and Bolling[1], and were found to be 0·214 and 4·77 per cent, respectively. If 3 : 5-di-iodo-tyrosine is the only reaction product, the fall in tyrosine content corresponds almost exactly to the amount of combined iodine (6·45 per cent). In agreement with this result, similar experiments with amino-acids showed that whereas tyrosine is readily iodinated under the above conditions, histidine reacts only to a negligible extent and tryptophane and proline not at all. Partial iodination of tyrosine gives more mono-iodo-tyrosine than di-iodo-tyrosine, contrary to Li's deduction[2] that tyrosine is slowly iodinated to mono-iodo-tyrosine, which then reacts instantaneously to give di-iodo-tyrosine.

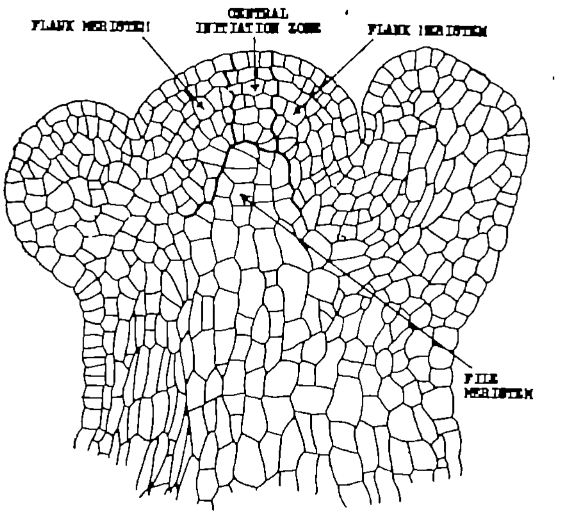
## Structure of the Angiosperm Inflorescence Apex

ALTHOUGH there is a considerable amount of information available concerning the structure of the angiosperm shoot apex, relatively little research has been carried out into the anatomical construction of the inflorescence apex. Grégoire's theory of the histological differences between vegetative and reproductive apices is well known to the student of developmental anatomy. He was unable to find tunica and corpus zones in the reproductive apices he examined. However, this observation has been challenged by recent workers, and these zones are now recognized in both types of growing-point. Few attempts have been made to interpret reproductive apices in the light of the cyto-histological zonation now generally recognized to be present in the vegetative apex[1]. Philipson[2] and Popham and Chan[3] have investigated the zonal changes that take place in the apex in the transition from the vegetative to the reproductive state in a number of dicotyledonous plants. It is claimed that, although central initiation, flank meristem and file meristem zones can be identified in the early inflorescence primordium, the central initiation zone later disappears and is replaced by flank meristem.

Anatomical investigations have been carried out by us on certain members of the Cruciferæ where the main inflorescence definitely terminates the leafy axis. Of the plants examined, *Arabidopsis thaliana* (L.) Heynh. proved the most instructive because it was possible to fix material grown under carefully controlled photoperiodic treatment, and thus apices in all stages from the purely vegetative to the flowering condition were obtained.

The first obvious change in the transition is an increased rate of cell division in the file meristem zone to convert the slightly convex vegetative apex into a large dome-shaped inflorescence primordium, down the sides of which extend the flank meristem. In this flank meristem are initiated first the cauline leaf primordia and then the flower primordia.

The cell-outline drawing shown is of a median longitudinal section through the *Arabidopsis* inflorescence apex with two flower primordia cut obliquely. The three main zones of the apex are labelled. The cells of the central initiation zone, as usual, stain less densely with protoplasmic stains than the surrounding flank meristem where mitotic divisions are to be observed frequently. This apex is more convex than the vegetative one, and file meristem cells, cut off from the lowermost cells of the central initiation zone, soon elongate in a plane parallel to the longitudinal axis of the inflorescence and undergo repeated transverse and longitudinal divisions. In the vegetative apex, the file meristem is poorly developed. Apart from these differences, the *Arabidopsis* apex producing flower primordia is essentially the same as that producing leaf primordia. Both differences are obviously related to growth processes. It has been stated[1] that the poor development of file meristem in the *Arabidopsis* vegetative apex is connected with the rosette habit of the plant. The active development of file meristem in the inflorescence apex, now under consideration, is obviously related to the active growth in a vertical direction of the inflorescence axis. The difference in shape of the two types of apex seems to be the result of the production of different types of lateral member. It has been observed, from an examination of numerous



Cell outline drawing of median longitudinal section of the inflorescence apex of *Arabidopsis*. (× 200)

series of sections, that a greater expansion of flank meristem needs to be reconstituted by the central initiation zone of the inflorescence apex before a flower primordium is initiated than in the vegetative apex before the initiation of a leaf primordium. As this greater expansion of flank meristem is being produced, the file meristem cells are undergoing active divisions to produce growth in length of the axis. A combination of these two growth processes will obviously produce a very convex apex.

Another interesting feature of this flowering apex is the retention of a two-layered tunica, in which no periclinal divisions occur, at all times during its growth. The flower primordia are initiated by periclinal divisions in the third flank meristem layer from the surface. This is in contrast to the initiation of leaf primordia by periclinal divisions in the second flank meristem layer. It is significant that this initiation of flower buds is similar to that of vegetative buds. The two-layered tunica, present in the early flower primordia, is disturbed later by the initiation of the floral members in its second layer.

These observations on *Arabidopsis* have been found also to apply to *Capsella* and *Iberis*. So far as we are aware, no other record has been made of the persistence of the central initiation zone in the inflorescence apex. It would seem then that, so far as these plants are concerned, vegetative and inflorescence apices are essentially similar and that the profound differences claimed by Grégoire cannot be applied to them. The inflorescence apex of these Cruciferæ is essentially similar to any shoot growing-point producing lateral members while actively promoting longitudinal growth of its subjacent axis. It is intended to publish this work in detail in due course.

We are indebted to Prof. F. G. Gregory and Mr. G. Hussey for the plant material on which these observations were made, and also to the Central Research Fund of the University of London for the loan of a microscope.

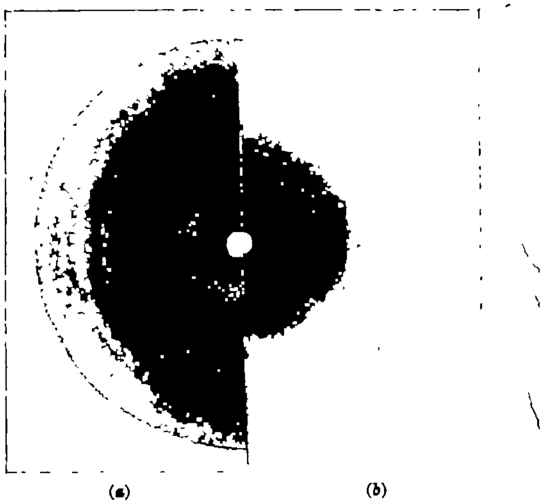
# Variability in the X-ray Diagram of the Cell Walls of the Marine Alga *Spongomorpha*

In a recent communication[1] we have shown by the methods of X-ray analysis that the two closely related green algæ *Cladophora* and *Spongomorpha* differ fundamentally in the submicroscopic organization of their cell walls. Whereas the cells in *Cladophora* filaments have walls in which the skeletal substance is a highly crystalline, well-oriented native cellulose (cellulose I), those of *Spongomorpha* contain a poorly crystalline, scarcely oriented modification of cellulose which might be mercerized cellulose (cellulose II) or a derivative. It was pointed out some time ago[2] that the air-drying of the material, necessary for X-ray investigation, does not produce any undesirable artefacts in algæ, and it was therefore concluded that the structures derived in this way could legitimately be applied to the fresh material. Even preservation in formalin or alcohol does not cause any observable change in the X-ray diagram.

These conclusions still stand for *Cladophora* and therefore presumably for the whole group of algæ with the *Cladophora* type of structure. While making a re-examination of *Spongomorpha*, however, in preparation for a projected publication on this and other differences from *Cladophora*, it has been noticed that the X-ray diagrams of *Sp. lanosa* var. *uncialis* and of *Sp. arcta* (the only species we have yet examined from the point of view of this note) vary with the manner of specimen preparation. If the material is dried first and then washed in distilled water (the normal treatment), the X-ray diagram is of the type already published[1] (Fig. *b*) and leads to the interpretation of structure mentioned above.

If, however, the material is washed in distilled water while alive and then dried, the X-ray diagram is of an entirely different kind (Fig. *a*), showing many more lines and indicating a much higher crystallinity.

Some of the lines which appear in this second type of photograph are due to the presence of salts and have been identified as belonging to potassium chloride and sodium chloride. Others, however, undoubtedly arise from organic material. The number of these latter lines varies from collection to collection, and we are not certain whether or not this represents



(*a*) (*b*)

X-ray photographs of *Spongomorpha lanosa* (*a*) specimen washed alive and then dried; (*b*) same specimen rewashed a seasonal variation. Some of the lines show marked orientation, and we conclude that these correspond to material incorporated in the walls.

The change in the X-ray diagram is apparently caused by the extraction of substances from the walls, and the dried extracts yield X-ray diagrams containing several lines which have disappeared from the diagram of the filaments. The extract undoubtedly contains material from sources other than the wall, but we have nevertheless thought it necessary to carry out a preliminary chemical investigation. The material chars on heating and the elementary analysis is as follows: C, 16·6 ± 0·3 per cent; N, 2·15 ± 0·3 per cent; H, 2·51 ± 0·3 per cent; S, 2·49 ± 0·4 per cent; P, 0·0 per cent. It contains a good deal of SO$_4''$, which may account for some of the sulphur, though it should be remembered that even then the sulphur may be organic[3]. This material appears to consist in part of organic substances of the nature of soluble proteins, but carbohydrates are absent. Somewhat similar material is extractable from *Cladophora rupestris* but in much smaller quantity and without noticeable effect on the X-ray diagram.

Among the soluble substances, known to be present in algæ, the one yielding an X-ray diagram most similar to—indeed, almost identical with—that of our material has proved to be synthetic thetine (dimethyl β-carboxyethyl sulphonium bromide) presented to us by Prof. F. Challenger of the Chemistry Department at Leeds. Prof. Challenger has since shown that dead *Spongomorpha arcta* produces large quantities of dimethyl sulphide on treatment with water, so that it must contain substances of the thetine type.

We thus have here X-ray evidence that substances which appear to occur in the wall are nevertheless extractable only after the filaments have been killed. This is of great interest in view of the growing conviction that the wall of a cell is more than a mere dead envelope. If, in addition, these substances include thetine, a trans-methylating agent, then this might be a point of decisive importance. These points will be discussed elsewhere when the results can be presented in fuller detail.

The work reported here is part of a programme financed through a grant from the Department of Scientific and Industrial Research, to which the thanks of one of us (R. D. P.) are due.

# Differential Fluorescence in Identification of Tobacco Trashy Leaf

Trashy leaf is brown, worthless leaf occurring in flue-cured tobacco; its prevalence causes a substantial loss to the Australian tobacco industry[1]. In the investigation of this phenomenon, it is essential that means be available of detecting trashiness at an early stage in uncured leaf. Cured leaf can usually be separated on physical properties into several grades varying from normal to fully trashy. This does not apply to uncured leaf, where gradation in trashiness remains masked. A method is described here whereby the presence of trashiness in dried uncured leaf can be readily detected. This method is based on the differential fluorescence of normal and trashy leaves under ultra-violet light.

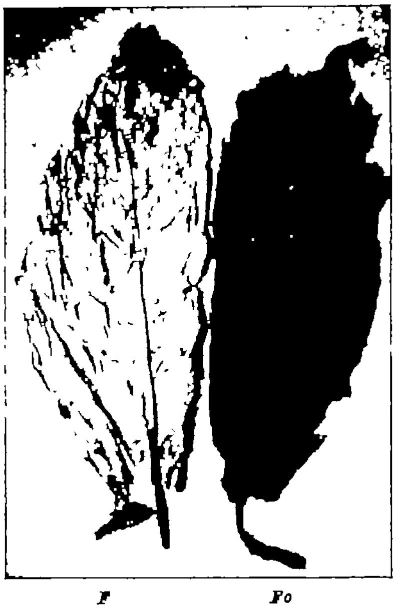

Fig. 1. Typical normal (*F*) and trashy (*Fo*) uncured tobacco leaves under ultra-violet light

It has been observed that the underside, but not the upperside, of normal tobacco cured or uncured leaves fluoresces with a brilliant bluish-white light tinged with green when exposed to ultra-violet radiation. On the other hand, fully trashy leaves, whether cured or uncured, remain dull, showing only a reddish-brown colour (see Fig. 1).

Some chemical characteristics of cured and uncured trashy leaves have been reported previously[1]. It has now been found that absence of fluorescence is associated with the chemical composition typical of trashy leaf (that is, low sugar, carbohydrate and amide–nitrogen and high total nitrogen, protein–nitrogen and ammonia–nitrogen). The data in the accompanying table are for fluorescent (*F*) and non-fluorescent (*Fo*) leaf from the same stalk position obtained from two rows of plants, one normal and the other showing extensive trashiness. Over the past two years, the use of ultra-violet light has indicated the degree of trashiness that can be expected in the cured leaf.

Chromatographic separation in various solvents, and absorption spectrum measurement of the fluorescent fractions, indicate that fluorescence in

Per cent total sugars, total nitrogen and protein–nitrogen contents (dry-weight basis) in fluorescent (*F*) and non-fluorescent (*Fo*) uncured tobacco leaves, and reducing sugars in corresponding flue-cured leaves estimated by methods described in ref. 1. Values are the means of several estimations and do not deviate from the true mean by more than ± 0·30 for sugars and ± 0·02 for nitrogen

| Leaf position on stalk | Total sugars | | Reducing sugars | | Total nitrogen | | Protein-nitrogen in 'protein' preparation | |

| 8, 9, 10 | 43·1 | 14·8 | 19·6 | 3·6 | 1·38 | 2·69 | 1·74 | 2·92 |
| 11, 12 | 44·2 | 13·8 | — | 3·0 | 1·48 | 2·59 | 1·73 | 2·92 |

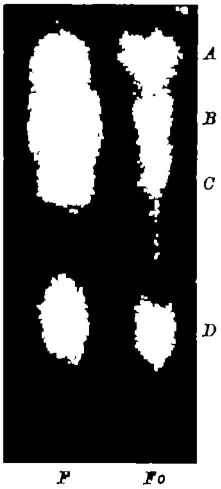

Fig. 2. Chromatogram of fluorescent components from normal (*F*) and trashy (*Fo*) leaves. These compounds are colourless in white light. *A* fluoresces with light grey, *B* with light blue, *C* with mauve and *D* (β-methylesculetin) with deep blue. (When taking the photographs a 2*A* Kodak haze filter was interposed between the object and camera lens)

tobacco leaf is a resultant of four major components *A*, *B*, *C* and *D*; typical chromatograms for normal and trashy leaves are shown in Fig. 2. The amount of fluorescent material present diminishes with increasing trashiness. There are indications that the relative amounts of the four components change as the fluorescence diminishes. Thus, there is a differential loss in component *C* with the development of trashiness. Component *D* has been isolated and identified as β-methylesculetin by comparison with an authentic sample. So far as is known, the difference in fluorescence of the two types of leaf and the presence of compounds represented by *A*, *B* and *C* has not been reported previously, although β-methylesculetin has been isolated from a variety of plants, including tobacco[2].

Further details of this work will be published elsewhere. I wish to express thanks to Miss I. D. Verners for sampling under ultra-violet light, and to Dr. R. J. Best of the Waite Agricultural Research Institute, Adelaide, for the authentic sample of β-methylesculetin.

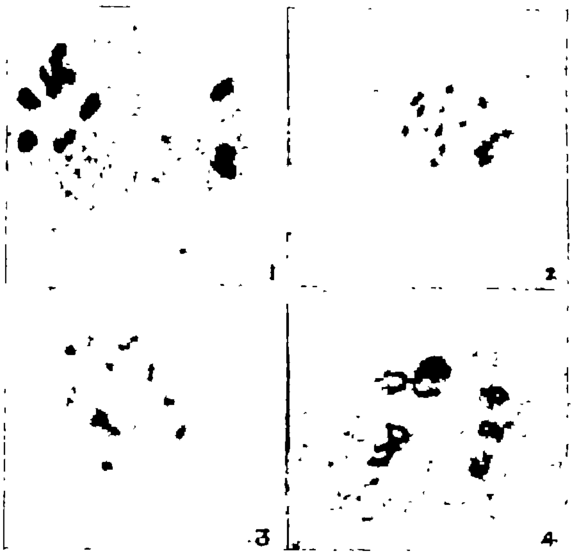
## Chromosomes of the Genus *Corchorus*

BANERJI[1] was the first to study the chromosome numbers in the genus *Corchorus*, and he found that seven was the haploid number. His survey included two varieties of *C. olitorius* Linn., four varieties of *C. capsularis* Linn. and *C. acutangulus* Lamk. Later, Nakajima[2] confirmed the observations of Banerji in the case of *C. capsularis* Linn.

The behaviour of chromosomes in meiosis in a large number of *Corchorus* species has been studied in this laboratory. In *C. trilocularis* Linn., pairing is normal and seven bivalents are the rule, although occasionally two chromosomes fail to pair and appear as univalents.



(1) Pollen mother cell showing hyperploidy; seven bivalents in one group and one univalent and one bivalent in another group (*C. fascicularis*). (2) Meiotic metaphase of pollen mother cell showing $n = 14$ (*C. siliquosus*). (3) Polyploid pollen mother cell, $n = 14$ in diakinesis (thirteen bivalents are in focus) (*C. fascicularis*). (4) Pollen mother cell showing one quadrivalent and five bivalents (*C. fascicularis*)

*C. siliquosus* Linn. is a natural polyploid and fourteen bivalents appear at $M_1$ (Fig. 2). Multivalents are infrequent, which shows that this is a polyploid by age. Pollen mother cells with one quadrivalent and one trivalent or with two trivalents have also been observed.

In *C. fascicularis* Lamk., pairing leads to the formation of seven bivalents with a single nucleolus, and occasionally two univalents appear due to failure of pairing. Often two bivalents are in connexion with two nucleoli. This species appears to be a structural hybrid, because a quadrivalent appears frequently (Fig. 4). By far the most interesting feature in this species is the occurrence of pollen mother cells with fourteen bivalents along with those bearing the normal seven (Fig. 3). There is an indication that these polyploid cells elongate and the fourteen bivalents separate into two groups of seven bivalents each. Abnormal pollen mother cells have been recorded which have arisen due to irregularities in the pre-meiotic divisions. These hyper- and hypoploid cells show varying numbers. When the cell receives more than the normal seven, there is a tendency to eliminate the extra bivalents and thus one cell retains the normal seven bivalents (Fig. 1). These abnormalities are observed in several other species of *Corchorus* under investigation and appear to be a characteristic of this genus.

Lagging at anaphase has been noticed. Multipolar spindles are formed in the second division, leading to the formation of micro-nuclei.

Further details of this work will be published later. We thank Dr. K. V. Srinath for his guidance, and Dr. B. C. Kundu, director of this Institute, for his encouragement.

## Longevity and Production in the Buffalo

An attempt has been made to estimate the extent to which selection for yield might be expected to influence the productive life of the buffalo. The calculations were carried out on data from animals that were not in the course of their productive herd-life. These animals were either dead, or culled from the herds studied. They were grouped together within herds according to their number of calvings. The average first lactation yield for the different groups was calculated and expressed as a percentage of their herd average. The total results for the herds were obtained by weighting the relative yields in similar groups in the different herds according to the number of animals contributing to them.

| No. of calvings | Relative yield (%) | $\sigma$ (gallons) | $C/V$ | No. of animals |
|---|---|---|---|---|
| 1– 2 | 84·1 | 112·3 | 29·6 | 41 |
| 3– 4 | 94·2 | 106·4 | 28·3 | 81 |
| 5– 6 | 104·3 | 108·8 | 26·6 | 65 |
| 7– 8 | 116·6 | 116·6 | 24·5 | 34 |
| 9–11 | 108·7 | 94·2 | 20·4 | 29 |
| Average and total | | | | |
| 5·00 | 100 | 107·8 | 26·6 | 250 |

The above results showed that the average productive herd life of these animals was five calvings. The coefficient of variation of the first lactation milk yield decreased from the first to the eleventh calf. The increase in the first lactation yield with the number of calvings made in the herds could be due to culling of low producers on lactations after the first, owing to the repeatability 0·55. However, the high first lactation producers lived up to eight lactations, and animals living longer, and of relatively lower first lactation yield, might be those with which the farmers built up their herds.

## Infectivity of Aphids after Several Hours on Tobacco Infected with Potato Virus Y

Watson showed that fasted *Myzus persicae* (Sulz.) were more than 60 per cent infective after 5 min. on tobacco infected with potato virus *Y*, but after 4 hr. on infected plants only about 10 per cent of the aphids were infective[1]. During investigations on the aphid transmission of potato virus *Y*, it was observed that, after several hours on tobacco, some aphids appeared to be feeding, others were just commencing to insert their stylets, and still others were wandering about the plant. The present communication reports which aphids transmit potato virus *Y* after a group has spent several hours on an infected plant.

Regular excretion of honeydew is generally accepted as evidence that an aphid is imbibing liquid from a plant[2], and previous work has shown that continuously feeding *M. persicae* usually have the stylets inserted into the phloem[3]. To learn whether *M. persicae* is infective after excreting regularly for more than an hour on tobacco infected with potato virus *Y*, single aphids were allowed to feed on infected leaves over filter paper which had been soaked in a solution of bromo-cresol green. Visible blue spots formed on the filter paper wherever drops of honeydew fell[4]. When an aphid fed continuously for more than an hour without changing its feeding site, three or four drops of honeydew fell on the paper within a circle of about 1 cm. diameter. Aphids that had excreted regularly for more than an hour from infected leaves were transferred to healthy White Burley tobacco plants (*Nicotiana tabacum* L.), and allowed to feed for several hours. Not one of twenty-five aphids tested in this manner transmitted the virus; but fasted aphids that spent 5 min. on the same infected plants were more than 60 per cent infective.

When feeding *M. persicae* are gently disturbed with a camel's-hair brush, the stylets can be seen, with the aid of a hand-lens, extending beyond the tip of the proboscis. Aphids do not appear to be injured when disturbed in this way, for the proboscis slowly elongates over the stylets, and usually feeding is renewed within a few minutes. The length of the stylets visible immediately after an aphid is disturbed may be taken as the distance they were inserted into the plant. About twenty-five feeding aphids were disturbed, and dropped at once into a hot fixative. The distance that the stylets of each aphid extended beyond the tip of the proboscis was measured under a microscope, and the aphids were then observed with a × 15 hand-lens. After a little practice and with the dead aphids as standards, it was possible to tell at a glance whether the stylets of disturbed aphids extended 25–50 μ, 50–100 μ, or more than 100 μ. When aphids with their stylets inserted less than 25 μ were disturbed, the proboscis elongated so quickly that the stylets could rarely be seen. Furthermore, after several hours on a plant, nearly all aphids that appeared to be feeding had their stylets inserted more than 25 μ.

About fifty *M. persicae* were transferred from cabbage to tobacco infected with potato virus *Y*. After a few hours on the infected plant, aphids that appeared to be feeding were disturbed, and the length of the stylets visible recorded as 25–50 μ, 50–100 μ, or more than 100 μ. Each aphid was then transferred to a healthy tobacco plant for several hours. Aphids were disturbed on various occasions from ten infected plants, and more than fifty aphids were tested for each of the three groups. A total of two hundred aphids was tested in all, but not one transmitted the virus. Disturbing the aphids did not appear to affect their ability to transmit, for aphids disturbed a second time about a minute after the stylets were re-inserted into the leaf were more than 30 per cent infective. Aphids that were observed to withdraw their stylets voluntarily, and disturbed about a minute after re-inserting their stylets, were also more than 30 per cent infective. Those aphids wandering about the leaves were observed to make a few feeding punctures lasting about a minute before settling down to continuous feeding. These aphids were transferred to healthy tobacco plants after they had completed one such puncture, and were more than 40 per cent infective. Thus, after several hours on tobacco infected with potato virus *Y*, virus was only transmitted by aphids commencing to insert the stylets, or by aphids that had made a brief feeding puncture.

The epidermis of the infected plants was about 20 μ thick. Therefore, aphids with their stylets inserted 25–50 μ must have only penetrated to the first or second mesophyll cells, and the majority of those with their stylets inserted more than 100 μ must have reached the phloem[3]. During feeding punctures lasting about a minute, the stylets are only inserted into the cells of the epidermis[5]. Thus, when the stylets were inserted into the epidermis, *M. persicae* acquired potato virus *Y* that could later be used to infect healthy plants; and aphids are never, or only rarely, infective when the stylets have penetrated as far as the mesophyll or to the phloem.

## An Unusual Form of Carbon

In the course of experimental work on the deposition of carbon in the brickwork of blast furnaces (deposition which may cause the disintegration of the bricks), it has been found by electron micrography that the carbon is deposited as minute vermicular growths which can penetrate considerable thicknesses of brickwork. The carbon is formed by the interaction of carbon monoxide and iron oxide in the so-called iron-spots in the brick. It has been found possible to reproduce this reaction in the laboratory by exposing samples of brick containing iron spots to the action of carbon monoxide at an optimum temperature of about 450° C. Moreover, a similar form of carbon growth is observed if iron ore, magnetite or any form of iron oxide is substituted for the brick samples.

The carbon vermicules have a characteristic appearance which is easily recognized—they may vary in thickness from 100 A. or so up to about 0·2 micron, and they are generally somewhat helical in form. Stereoscopic examination has shown that many of the thicker threads consist of a number of thin ones twisted together in the form of a rope. We have, so far, been unable to find any other source of carbon of similar appearance, with the possible exception of soot from a domestic chimney where the same reaction may well have taken place.

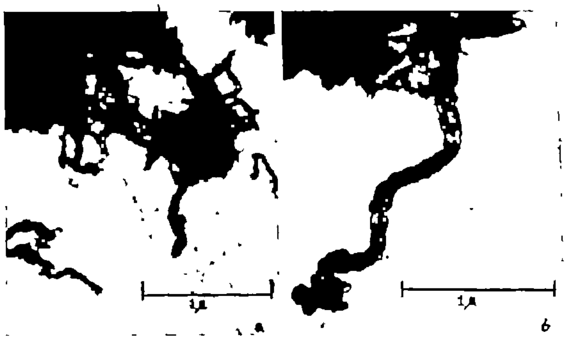
X-ray examination of the deposited carbon showed, in addition to amorphous carbon, cementite ($Fe_3C$) and an iron percarbide ($Fe_{20}C_9$). It is suggested, therefore, that the following reactions may take place:

$$\begin{aligned} Fe_3O_4 + CO &\rightarrow 3FeO + CO_2 \\ FeO + CO &\rightarrow Fe + CO_2 \\ 3Fe + 2CO &\rightarrow Fe_3C + CO_2 \end{aligned}$$

$$\begin{tikzcd}[column sep=small] & Fe_3C \arrow[dl] \arrow[dr] & \\ Fe_3C \rightarrow 3Fe + C & & \begin{array}{c} 20Fe_3C + 14CO \rightarrow 3Fe_{20}C_9 + 7CO_2 \\ 3Fe_{20}C_9 \rightarrow 20Fe_3C + 7C \end{array} \end{tikzcd}$$

Thus the reaction $2CO \rightarrow CO_2 + C$ may be considered to be catalysed either by iron which is alternately converted to cementite and back to iron, or by cementite which is alternately converted to the percarbide and back to cementite.

It would appear that the catalyst, whether it be iron or iron carbide or both, is formed originally as specks on the surface of the iron oxide—each speck giving rise to a thread of carbon. An isolated speck produces a thin thread, but the threads from a collection of catalytic points become twisted and probably coalesce to produce the characteristic vermicule. Once the growth of carbon has commenced, the position of the catalyst is less certain. We suggest that the particles of catalyst are located on the growing ends of the threads. This would explain the coalescence of multiple threads and also the mechanism by which the carbon can penetrate the bricks.



(*a*) Carbon growth in firebrick after 30 hr. in carbon monoxide at 450° C., showing mass of characteristic vermicular threads. (*b*) Large vermicule formed by coalescence of smaller threads

## *Murex* from the Red Sea

In the early months of 1951, Sir John Graham Kerr collected some three hundred *Murex tribulus* shells on the western shore of the Great Bitter Lake south of the village of Fayid. It will be remembered that the entire animal population has been introduced subsequent to the cutting of the Suez Canal in 1869, which opened the way for immigrant organisms from the Red Sea. Now, granted the inherent tendency of living creatures to vary when relieved of the shackles of environment, Sir John argued that, in their new environment of the Bitter Lakes, these *Murex* specimens had had an opportunity of responding to this tendency, and hence the remarkable variety of sculpture in the random collection. Moreover, this variation exhibited in spines and tubercles is not a matter of mere superficial markings, but rather of deep-seated causes such as the localized growth of the mantle edge or the depth in the mud occupied by the individual animal. The shells were in perfect condition, there being practically no tides in the Bitter Lakes and no violent wave action, and the bottom is soft mud.

Sir John very kindly presented me with this collection for the Notre Dame Museum. My successor in the lectureship at Notre Dame, Sr. Marie Josephine Parkes, has carried out a most painstaking investigation in detail of the variations shown by the individual shells, but is now held up at this point for lack of a corresponding series of shells from the open waters of the Red Sea. The object of this communication is to make an appeal for help to anyone with an opportunity for collecting in the Red Sea to fill this deficiency. A photograph of the particular species of *Murex* will be gladly forwarded to anyone willing to help.

## Monday, April 27

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4 45 p.m.—Sir Rudolph Peters, F.R.S.: "Inhibitors and Intracellular Chemical Dissection".* (Further Lectures on May 4, 11 and 18.)

University of London (in the Eugenics Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. W. Feller (Princeton): "On Diffusion Processes and their Statistical Applications".* (Further Lecture on April 29.)

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—"Induction and Scientific Legitimacy" (Chairman's Address).

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. H. Ironmonger: "The Tyndall Manuscripts".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p m.—Prof. H. S. Taylor, F.R.S.: "Catalysis—Modern Trends".* (Further Lecture on April 28.)

## Tuesday, April 28

Wool Education Society (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.15 p.m.—Mr. John Barritt: "The Mothproofing of Wool".

## Tuesday, April 28—Friday, May 1

Library Association (in the Pier Pavilion, Llandudno).—Annual Conference.

Royal Sanitary Institute (in the White Rock Pavilion, Hastings).—Health Congress.

## Wednesday, April 29

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1), at 9.45 a.m.—Special Meeting on "Boron in Steel".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. O. H. Wansbrough-Jones: "The Scientist's Place in the Services" (Sir William Jackson Pope Memorial Lecture).

Textile Institute (at the University, Bristol), at 3 p.m.—Annual General Meeting; at 4 p.m.—Dr. C. M. Whittaker: "Common Sense and Colour in Textiles" (Mather Lecture).

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. George Wald (Harvard): "The Molecular Basis of Vision".*

Geological Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting; Presidential Address on "The Evolution of the Shrinking Earth".

Royal Meteorological Society (at 49 Cromwell Road, London, S W.7), at 5 p.m.—Dr. T. W. Wormell. "Lightning" (Symons Memorial Lecture).

## Thursday, April 30

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Miss Edith Bulbring, Prof. J. H. Burn, F.R.S., and Miss Heather J. Shelley: "Acetylcholine and Ciliary Movement in the Gill Plates of *Mytilus edulis*"; Mr. F. W. Shotton: "The Pleistocene Deposits of the Area between Coventry, Rugby and Leamington and their Bearing upon the Topographic Development of the Midlands".

Society of Chemical Industry (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. R. T. Colgate: "Science, Food and the People" (Third H. E. Armstrong Memorial Lecture).

Chadwick Public Lecture (in the Lecture Hall, Walker Art Gallery, William Brown Street, Liverpool), at 7.30 p.m.—Prof. S. E. Finer: "Public Health—a Comparison between the Age of Chadwick and our Own".*

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7 30 p.m.—Prof. H. S. Taylor, F.R.S.: "The Scientific Problems of Surface Catalysis".

## Thursday, April 30—Friday, May 1

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1).—Annual General Meeting.

## Friday, May 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. J. Kampé de Fériet (Lille): "The Statistical Theory of Turbulence".*

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. J. Reeman, Mr. R. W A. Buswell and Mr D. G. Ainley: "An Experimental Single-Stage Air-cooled Turbine".

## Friday, May 1—Saturday, May 2

Society of Chemical Industry (joint meeting of the Food and Agriculture Groups and the South-Western Section, at Newton Abbot).—Symposium on "Potatoes as a Crop and an Industrial Raw Material".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in the History of Mechanical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (April 30).

Assistant Lecturer in Biochemistry at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 1)

Senior Assistant Physicist in the Radiotherapy and X-Ray Diagnostic Departments—The Clerk to the Governors, St. Thomas's Hospital, London, S.E.1 (May 2).

Lecturer in Experimental Physics, and Assistants in Experimental and Theoretical Physics—The Secretary, The University, Aberdeen (May 5).

Assistant Lecturers in Chemistry—The Registrar, The University, Manchester 13 (May 6).

Assistant Lecturer in Botany (preferably with special interest in ecology and morphology)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 8).

Experimental Officers (Ref. F.139/53A) and Assistants (Scientific) (Ref. F.140/53A) in the Chemical Inspectorate, Ministry of Supply, for analytical work related to the Atomic Energy Production programme in establishments at Sellafield, Salwick, Capenhurst and S.E. London—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S W.1, quoting the appropriate Ref. No. (May 9).

Ph.D. in organic or biochemistry, for an applied chromatography research scheme—Dr. R. T. C Pratt, National Hospital, Queen Square, London, W.C.1 (May 9).

Scholarship in the School of Theoretical Physics—The Registrar, Dublin Institute for Advanced Studies, 64 Merrion Square, Dublin (May 11).

Geologists at the Geological Survey and Museum—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.168/53 (May 14).

Assistant (male, with degree in horticulture, agriculture or botany) in the Scientific Liaison Section—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (May 16).

Reader or Senior Lecturer in Civil Engineering—The Registrar, The University, Nottingham (May 16).

Scientific Technical Officers for metallurgical and chemical research at the Central Research Establishment, Isleworth—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/623 (May 18).

Assistant Lecturer in Statistics—The Secretary, Bedford College, Regent's Park, London, N.W.1 (May 22).

Scientist (Grade I) to supervise the design and operation of pilot plants—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, Glos, quoting TT/620 (May 23).

Lecturer in Philosophy at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 31).

Lecturer in Geology and Mineralogy—The Secretary, The University, Aberdeen (June 1)

Pfeiffer Scholarship in Aeronautics—The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks (June 1).

Lecturer (Grade II) in Chemistry (with special qualifications in physical chemistry, and who should have undertaken independent research in some branch of this subject, other than reaction kinetics)—The Registrar, The University, Reading (June 13).

Physicist (with university honours degree in science, or equivalent qualifications, with research experience in the use of X-ray diffraction, preferably as applied to studies of the structure of proteins or high polymers) to the Biochemistry Unit, Wool Textile Research Laboratories, Parkville, Melbourne, to participate in an intensive programme of research on the structure of wool and other fibrous proteins by chemical and physical methods—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 462/51 (June 26).

Lecturer in Mathematics at the University of Natal, Durban—The Secretary, Association of Universities of the British Empire, 5 Gordon Square, London, W.C.1 (June 30).

Assistant Professor in the Department of Civil Engineering—The University of British Columbia, Vancouver, B.C., Canada.

Associate Professor of Mathematics—The Acting Head of the Department of Mathematics, Memorial University of Newfoundland, St. John's, Newfoundland, Canada (apply by air mail).

Biologist (Fishery Research), Kenya, for survey of freshwater fisheries—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.152/7/01

Geologist in Northern Rhodesia—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE. 105/3/01.

Geologist in Tanganyika—The Director of Recruitment, Colonial Office, Great Smith Street, London, S W.1, quoting CDE.105/8/03.

Lecturer or Assistant Lecturer in Geology, an Assistant Lecturer and a Demonstrator in Organic Chemistry—The Registrar, The University, Nottingham.

Metallurgist (with honours degree or equivalent) to take charge of small metallurgical and chemical laboratory, and Research Engineers (good honours degree essential) for (*a*) general automobile engineering problems, (*b*) investigations concerning mechanical properties (in particular, fatigue strength) of materials and components, (*c*) investigations into loadings experienced by vehicle components on the road, riding characteristics of vehicles, etc—The Director, Motor Industry Research Association, Lindley, Nuneaton.

Mines Surveyor in Uganda—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE. 103/9/03.

Physicists (with at least second-class honours in physics, applied mathematics or engineering) for fundamental research on felt and applied research in the felt-making industry—The British Hat and Allied Felt-makers Research Association, Stanley House, Manchester Road, Fairfield, Droylsden, Manchester.

Professor of Experimental Physics, Professors (2) in Chemistry (one in physical chemistry), a Professor of Mathematics, a Professor of General Mechanics and Oscillations (mechanics of continua), an Associate Professor (general mechanics and vibrations), a Senior Lecturer in Physics (with special qualifications in nuclear physics or solid state physics), a Senior Lecturer in Chemistry, a Senior Lecturer in Mathematics (with special qualifications in mathematical statistics), a Senior Lecturer in the Division of Mechanics, Professors (2) in the Department of Chemical Engineering (one with special qualifications in food technology and biotechnology), a Professor of Metallurgy, Professors (2) of Electrical Engineering or Electronics and Telecommunications Engineering, an Associate Professor of Electrical Power Engineering, a Senior Lecturer in Electronics and Telecommunications Engineering, Professor of Mechanical Engineering (with special qualifications in thermodynamics and machines), a Professor of Hydraulic and/or Sanitary Engineering, an Associate Professor of Hydraulic and/or Sanitary Engineering, an Associate Professor (with special qualifications in tooling processes, machine tools and metrology), a Senior Lecturer (with special qualifications in applied thermodynamics and machine laboratory work), a Senior Lecturer of Hydraulic and/or Sanitary Engineering, a Professor or Associate Professor or Senior Lecturer of Aircraft Structures, a Professor of Aircraft Propulsion or Applied Aerodynamics, an Associate Professor of Aircraft Propulsion or Applied Aerodynamics and two Senior Lecturers, and a Professor or Associate Professor in Farm Power and Machinery; in the Hebrew Institute of Technology, Haifa, Israel—The Secretary, Technion Society of Great Britain, 13 Mansfield Street, London, W.1.

Senior Research Fellows and Research Fellows to work in the Department of Theoretical Physics, Australian National University, Canberra, on problems of nuclear and particle physics and in field theory—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

Senior Research Worker and a Research Assistant, to undertake a fundamental study of the viscosity of liquid metals—The Registrar, The University, Edmund Street, Birmingham 3.

Technical Officer (with degree or diploma in agriculture, horticulture or biology) for potato trials—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

# ADULT EDUCATION IN GREAT BRITAIN

SPEAKING in the House of Commons on April 23, Miss Horsbrugh, Minister of Education, announced that the grants for adult education next year would be the same as for this year. Thus has ended a period of uncertainty and vigorous discussion which followed the proposal early this year for a reduction of government support of this aspect of the national educational system. Miss Horsbrugh stated that, after consideration of information provided by bodies responsible for adult education in Great Britain, she had concluded that the arrangements by which government support was afforded required reviewing in the light of post-war developments. She proposes, therefore, to set up a small committee to advise her on administrative and financial aspects; until the committee reports, the grants are to be maintained, and even additional assistance may be made available.

The Prime Minister's letter of March 13 to the Trades Union Congress had already stated that no actual decision to cut grants had been made. There was, he added, perhaps no branch of the educational system of Great Britain which should more attract, within its particular sphere, the aid and encouragement of the State than adult education. "How many must there be in Britain, after the disturbance of two destructive wars, who thirst in later life to learn about the humanities, the history of their country, the philosophies of the human race, and the arts and letters which sustain and are borne forward by the ever-conquering English language? This ranks in my opinion far above science and technical instruction, which are well sustained and not without their rewards in our present system. The mental and moral outlook of free men studying the past with free minds in order to discern the future demands the highest measures which our hard-pressed finances can sustain."

The Prime Minister's words recall those of Prof. S. E. Raybould, the first occupant of the new chair of adult education in the University of Leeds, in the survey of university extra-mural education in Great Britain which he contributed to a volume, "Universities in Adult Education", recently issued by the United Nations Educational, Scientific and Cultural Organization[*]. Most valuable of the results of such education, Prof. Raybould thinks, is "the development of habits of systematic study, of critical thinking, of disciplined discussion; and the result has been the more widespread diffusion throughout the population of the qualities of tolerance, judgment and responsibility which are necessary for democratic life". Nevertheless, to recognize the necessity and importance of adult education is, however, as the Prime Minister concluded, no reason for not looking through the accounts and making sure that all that we can give is turned to real advantage.

The Prime Minister's letter shows clearly that the Government is concerned, and rightly, to ensure that there are no instances of our limited funds being spent without proportionate result, even on a vital service, where this could be corrected by careful investigation. It is concerned also to examine the prospect of increasing the income for adult education from sources other than, or in addition to, the Exchequer grant. The possibility of an increase in students' fees at least warrants careful attention, and so too does the list of subjects for which public grants are payable.

---

[*] Universities in Adult Education. (Problems in Education, 4.) Pp. 172. (Paris: Unesco; London: H.M. Stationery Office, 1952.) 8s. 6d. net.

The agitation will have done good if it stimulates in Britain a more searching public discussion of these matters. Something much more vital, however, is involved than the amount of public grants for such purposes under the conditions of to-day. The fundamental issue is the appropriateness of the whole system of adult education in present conditions. The raising of the school-leaving age and the extension of public grants for scholarships and awards have doubled the number of university students, and the majority of the latter now receive grants from public funds in some way or another. This has transformed the social structure as well as placed severe strains on the universities, and the questions can fairly be asked: Are the methods by which adult education has been conducted in the past really adapted to the new conditions? What should be the function of the Workers' Educational Association to-day? How far is the extra-mural work of the universities in this field consistent with and not inimical to their other duties and the maintenance of academic standards?

Like recent discussions on higher technological education and on the universities and industry, consideration of the place of the universities in adult education brings us to the question of the purpose and function of a university. Without a clear conception of the nature of a university and of its purpose and function in the society of which it forms a part, the allocating of its resources to the best advantage, the scope of its studies, the balance of research and teaching, and of staff and students cannot wisely be determined. How serious such problems have become may be judged from Sir John Stopford's remarks at a recent dinner of the Yorkshire Association of Graduates of Manchester University.

One of the biggest problems of British universities to-day, said Sir John, is the danger that public work may deflect university dons from their prime duty of teaching and research, and there is a possibility that this may get out of hand. He said that at Manchester there are always four or five members of the staff away on the Continent advising foreign governments, and others are helping the British Council or government departments in Britain. The outside responsibilities of the universities have increased enormously since the War, and Sir John referred in particular to the claims made by the National Health Service on the medical staff of the universities. The heavy responsibility of big research enterprises is a further factor. Many such proposals should be rejected by the universities, in Sir John's opinion, because the schemes are too big for the limited resources of a university and would be better undertaken by industry or a research institute.

Such proposals, like projects for sponsored research, must clearly be considered in relation to Great Britain's organization and resources for scientific and industrial research in general, and not purely against the existing resources and commitments of the universities. Above all, however, they should be considered against some clear view of the nature and purpose of a university such as Dr. A. L. Goodhart sought to formulate in his Haldane Memorial Lecture last May (cf. *Nature*, 169, 986; 1952). Only when we are clear in our minds as to the precise functions of a university and what it should impart to its graduates can we proceed to decide exactly what should be the nature of its teaching or the duties of its staff. Dr. Goodhart laid all the weight of his emphasis on the teaching function of the university: that to his mind is and always will be the primary function. Research of great importance will always be proceeding in any university worthy of its name; but research is not, in his view, the essential purpose of the university. Dr. Goodhart, agreeing with Newman, then urged that it is not what a man has learned but how he has learned it that matters; and he claimed that the habit of mind the university should seek to impart does not depend on the particular subject which the student is studying. The basic mental training of the science scholar and the arts scholar is the same, and failure to recognize this means failure to understand the true purpose of a university, and what it can give to its students. Elaborating this further, Dr. Goodhart stated that clarity of thought and intellectual curiosity are the two transcendent qualities which a university should impart to its members. The first is of supreme importance in national life to-day, and the second, with its emphasis on inquiry, marks the essential difference between a university and a purely technical school.

Dr. Goodhart pleaded that in determining how many students it should admit and what subjects it should teach, a university should above all be mindful of the importance of maintaining its standards, and of ensuring that it fosters the adventurous inquiring mind which has been trained to be accurate; this is in line with Lord Haldane's own ideal of a university. It is encouraging to find that such ideas were reflected in many of the addresses and discussions at the Conference on Industry and the Universities at Ashorne Hill last October, particularly in connexion with the qualities which industry seeks in the university graduate. Their force was equally admitted by Prof. R. S. Edwards in a plea for administrative studies in the universities (*Three Banks Review*, September 1952)—a plea which, however, found little support at that Conference. Prof. Edwards's purpose, however, was at least in part to indicate what is already being done by the universities in this field, and particularly the opportunities for research in the fields lying between the natural and social sciences. The value of such research was stressed at an earlier conference of the Federation of British Industries, when a plea for closer co-operation between industry and the universities in the study of industrial organization and management was advanced by Dr. F. A. Wells.

In this whole context it is appropriate that, as was urged by Prof. Raybould in his book "The English Universities and Adult Education" in 1951, the universities should reconsider their place in extra-mural work, and the nature and extent of their contribution to adult education. Simultaneously, but independently of the Government's suggestions concerning the financial and administrative aspects of adult education as a whole, the value and utility of the Workers' Educational Association—the other means through which Government grants to education have been given in the past—has been challenged by critics, who point to the public library as a more appropriate instrument for public support of adult education. The character of the Workers' Educational Association has indeed changed. By 1932, the proportion of manual workers had dropped to a third and is now not more than 18 per cent. In 1951 the three-year tutorial classes which form the hard core of academic studies were only 14 per cent of all classes, with 12·5 per cent of all students.

Prof. R. H. Tawney's call in 1950 for a return to the first principles of strong working-class membership and exacting educational standards has to be considered in the light of the great social changes of the past fifty years, and especially in public education. To concentrate on working-class students who are capable of sustained study at the university-level means acquiescence in a drastic contraction of the work and influence of the Workers' Educational Association, whereas, in fact, its activities have expanded. Since 1930 the number of students attending its classes has nearly doubled, and the question which has to be asked is whether the Association is the appropriate 'responsible body' for all these activities. Inquiry might indicate that some of them should be entrusted to the university extra-mural departments which are already working on parallel lines, while others might be made more nearly self-supporting or entrusted to local education authorities, which now have responsibilities for further education.

What is clearly required is fresh thinking about the whole problem of further education, and the responsibilities and effectiveness of the several agencies working in that field, in the light of the new social situation and its current trends.

# ZOOGEOGRAPHY

## Ecological Animal Geography

By Prof. W. C. Allee and Karl P. Schmidt. Second edition. An authorized edition, rewritten and revised, based on "Tiergeographie auf ökologischer Grundlage" by the late Richard Hesse. Pp. xiii+715. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 76*s*. net.

WHEN the originator of this large compilation, Richard Hesse, wrote his German book in 1924, the science of animal ecology was in its early development. That of zoogeography, though with a long history behind it, was confused by the cross-currents of unbridled speculation, now happily beginning to be brought into more orderly notions by the aid of palæontological evidence. In 1924, also, zoologists were beginning to turn towards physiological facts for explanations of the limitations of the range of species and geographical differences of external form. It was natural and useful that the emphasis of Hesse's book should be given to a description of the geographical and physical zones of the world, the more obvious adaptations of animal life to existence in them, and to the relating of animal form and function to physical gradients. Ideas of population—and indeed of time changes at all—were mainly excluded. The American authors who have largely rewritten this book for the second time (the first version appeared in 1937) have not deviated very much from this general outlook, except to mention rather more modern work both on ecology and zoogeography. The book is still a static picture of the world and its animal life—it presents a series of huge 'life groups' from different parts of the sea, land and fresh water; and historical and dynamic processes are almost completely excluded from the story. It is a series of pictures, not the foundations of a special science, for any development from this kind of ecological animal geography would have to study physiological or genetical process, population balance or zoogeographical history. For this reason the book is fairly dull to read, an effect increased by the authors' passion for stating every bit of information in the same tone of voice. There is a curious mingling of absolute platitudes like "Sufficiency of water is most completely assured to animals that live in it" with tongue-twisters for the student like "the camel is a stenohygric animal of arid country", which may at first reading conceal the fact that a tremendous amount of careful scholarship and distillation of written knowledge has gone into making the treatise; and since much zoological information is still rather a chaos of small bits about species or taxonomic groups, except in so far as it has been brought into the field of evolution theory, one must welcome such a solid attempt to describe the faunal features of the world as a whole.

The book falls into four sections. The first is general and, as usual in the Chicago school of zoology, starts with the physical and geographical environment and ends with animal communities (biocœnoses). An indication of the verbal atmosphere in these first 165 pages is illustrated by the following sentence: "The biochores and superbiochores are finally combined into still higher groupings, which may be called 'biocycles' ". Some readers might feel that they needed a 'biocycle' to enable them to get around the 'chores' of reading this sort of superbly unnecessary jargon. Phrases like the "spruce-moose biome" are likely to amuse, without illuminating.

The two succeeding sections, on marine and fresh-water animal life respectively, are much the best parts of the treatise. They are clearly the result of a great deal of search for good information, and, although the separate subjects have to be dealt with in a condensed form, there is no doubt of their real value both to students and to zoologists generally who cannot find time to keep abreast with the wide-ranging research that is going on in our oceans and lakes. It is when we reach the last section, on the distribution of terrestrial animals, that compression defeats its aim. One cannot be satisfied with the eleven lines that are devoted to the coniferous forests of the Holarctic region, or the two and a half pages about the deciduous forests. Modern ecological surveys of the Arctic land regions are not mentioned.

It will be seen that this book is a serious and great effort of scholarly compilation, covering such a huge field that its omissions are not entirely unexpected. It falls somewhere between an encyclopædia and a text-book; but it will prove a valuable work of reference for facts, so long as it is realized that the facts are bound to be very incomplete, that the abundance of rolling jargon does not conceal a dynamic philosophy about animal life, and that the future of zoology lies in the study of processes rather than of panoramas. CHARLES ELTON

## JAPANESE OPISTHOBRANCHS

### Opisthobranchia of Sagami Bay

Collected by H.M. the Emperor of Japan. Described, with an Introduction, by Dr. Kikutaro Baba. Edited by Dr. Hirotaro Hattori. Pp. 194+50 plates. (Tokyo: Iwanami Shoten, 1949.) £7.

THERE is now ample evidence of the existence of an opisthobranchiate fauna of great variety and wealth in the seas around Japan—a fauna made the more interesting by its admixture of temperate and tropical forms. The first hint of this was given as long ago as 1880–81, when Rudolph Bergh[1] published his "Beiträge zur Kenntniss der japanischen Nudibranchien", which, although containing descriptions of only fifteen species, showed that a considerable range of types existed. Bergh's publication, based on collections made by a number of naturalists, was the first attempt at a comprehensive account of the Japanese species. This pioneer work was followed in later years by accounts of further collections, notable among which is Sir Charles Eliot's[2] "Japanese Nudibranchs", published in 1913. This latter is a report on the nudibranchs then in the collection of the College of Science in the Imperial University of Tokyo and describes no fewer than forty-three species belonging to several groups. Coming to more recent times, no one has done more to add to our knowledge of the Japanese representatives of this group of the Mollusca than Dr. Kikutaro Baba, whose long series of investigations, beginning in the early 1930's, are happily still in progress. His contribution to the work recently compiled by the Japanese Imperial Household has been a major one.

It is well known to men of science in general that H.M. the Emperor of Japan is keenly interested in marine biology, and, as is recounted in the preface to this volume, he has long made it a rule, every time he goes to stay at his villa at Hayama, on the eastern shore of Sagami Bay, to organize and take part in shore collecting expeditions. Detailed surveys of many parts of the shore of the bay itself and of the many off-shore islands have been made, and frequently he has gone to sea to collect by dredging, trawling and other means off the coasts of Enoshima and Jogashima Islands in water three hundred or more metres deep.

Sagami Bay is situated roughly in the centre of Japan proper, on the south-east coast of Honshu, and, clearly, many factors combine to make it a rich collecting ground. Bounded on the east by the Miura Peninsula and on the west by the Izu Peninsula, the bay has a wide opening to the ocean. South from its mouth there extends the long chain of the Izu Shichto Islands. The shore is good for inter-tidal collecting; off-shore rocks and reefs abound, forming rich habitats, and beyond them there is water of varying depths dropping to a thousand metres or more in the central part of the bay. Also, at certain seasons of the year, a branch stream of the warm Japan Current (*Kuro-shiwo*), flowing eastwards between Oshima Island and the southern tip of the Izu Peninsula, enters the bay, bringing with it a rich flora and fauna including many species characteristic of more southern waters.

The series of investigations, part of which forms the basis of this book, have covered a period of somewhat more than twenty years and have resulted in the amassing of a large number of specimens of marine algæ and animals belonging to various phyla now suitably preserved for future research. Whilst providing a comprehensive account of the opisthobranchiate Mollusca of this region, it is to be borne in mind that the work is concerned solely with those species taken by the Emperor himself at various stations in Sagami Bay. It is the first volume to be published by His Majesty's Biological Laboratory and, so we are told, will be followed in due course by others on different groups. The species recorded in it are described by Dr. Baba, who has also written the brief introduction. The coloured figures, all of which have been painted from living specimens, and of which there are no fewer than 170, have been executed by the late Hiroo Sanada and Shiro Kato, and the whole work has been edited by Dr. Hirotaro Hattori, chief of the Biological Laboratory of the Imperial Household.

Although partly translated into English, most of the book is written in Japanese, the difficulty of obtaining an adequate translation of which has occasioned the somewhat long delay in the appearance of this notice. That the section in English, which follows the initial Japanese part, is approximately half as long (64, as against 114 pages in Japanese) is not due solely to typographical differences between the two languages, but largely to the fact that a number of interesting and important chapters in Japanese have not been translated into English. Although this has been done, one must suppose, in order to keep the book to a reasonable size, it is much to be regretted, for the topics dealt with in them range from an historical review of work on Japanese forms, an account of geographical distribution, and a brief review of different modes of classification to the phylogeny and relationships of the Opisthobranchiata—matters of great interest to the malacologist in particular and to the zoologist in general.

The longest section in both the Japanese and English parts is the chapter on classification, which contains brief, though evidently accurate and adequate descriptions, accompanied by line figures, of the species which have been collected. One hundred and forty-three species are recorded, fifty of which are new, and five new genera have been established. A world-wide acquaintance with opisthobranchs would be necessary before pronouncing judgment on the validity of the new species described; but it is encouraging to note that in the majority of them the descriptions have been based on series of specimens often collected at different times and from different localities. The description of each species is followed by the briefest of field notes giving the dates and localities of collection and details of distribution.

Coloured figures are an essential accompaniment to any taxonomic work on opisthobranchs, and the fifty plates which form the last section of the book are attractively produced, sometimes strikingly beautiful, and, so far as can be judged, true to life.

There is no doubt that this work is a valuable contribution to marine zoology and in particular to our knowledge of the Opisthobranchiata of Far Eastern seas; but let us hope that the Emperor and his team of investigators will see fit to follow it up with further publications dealing with some other aspects of the biology of this interesting group of the Mollusca. With such admirable facilities for study in what must be the finest of collecting grounds, it is not too much to expect that observations on general biology, spawning habits and larval and post-larval development, to mention only a few of the topics on which detailed information is so sadly lacking, will be undertaken.

The book is expensive in British money; but it is well printed and in all respects most attractively produced. It is stoutly bound in pale green with gold lettering—in English on the cover and Japanese on the spine. To the British reader, who can scarcely be expected to boast familiarity with all the localities mentioned, the inclusion of a large-scale map of Sagami Bay and neighbourhood would have been an asset.

# TEXT-BOOK OF LIGHT FOR DEGREE STUDENTS

## Light

(Student's Physics Series, Vol. 1.) By Prof. R. W. Ditchburn. Pp. xxii+680. (London: Blackie and Son, Ltd., 1952.) 45s.

THIS book is a most welcome addition to the series which contains, for example, J. K. Roberts's "Heat and Thermodynamics". Despite the multiplicity of books on the subject of light, there are few which are suitable for honours students, and still fewer which approach the degree of completeness and attention to detail shown by this volume. Prof. R. W. Ditchburn is to be congratulated on the production of a work which is a testimony both to his extensive knowledge of the subject and to his powers as a teacher.

The book covers all that is required in physical optics for a degree course, starting from Intermediate level; it does not include geometrical optics, as the title might imply. Problems, on which the student can test his powers, are interspersed throughout the book, and often brief guides to the methods of solution are given.

Having made clear my unqualified opinion of the book as a whole, I should like to direct attention to two aspects in which I feel that the author does not live up to the high standard which he has set for himself. First, he claims, in the preface, that the wave theory has been described in such a way that the quantum theory appears as a natural development. One looks forward to some interesting new approach to the teaching of this rather awkward episode in the history of science, but it is not there; one meets the usual presentation of the quantum-theory as a device for explaining, for example, odd effects such as photoelectricity.

Secondly, it is possible that more could be made of Abbe's theory of image formation. I agree that the treatment is at least as full as in any other text-book of light; but, in a book in which so much attention is paid to practical details, it is a pity that the author has not taken the opportunity to reproduce some practical illustrations, which would make the theory so much more real to the student. The concept of resolving power is of such importance in physics that it is unsatisfactory merely to refer students to the original work, which is often not readily accessible to them.

The difficulty is aggravated by the fact that the only practical illustration related to resolving power (Fig. *l*, Plate III) is given a misleading legend; it is actually the Fraunhofer diffraction pattern of a single circular aperture obtained from two point sources near the limit of resolution, but it is described as the "pattern due to two circular apertures which are just resolved".

These are the only aspects of the book which I feel to be unsatisfactory. There are some very minor errors, such as the omission of two minima in Fig. 6.3, and the mention of "the molecule" of mica; but, on the whole, the reading of the book can engender nothing but admiration that one man can cover so adequately the different aspects of physical optics.

H. Lipson

# LEAF-MINING INSECTS

## Biology of the Leaf Miners

By Prof. E. Martin Hering. Pp. iv+420. ('s-Gravenhage: Dr. W. Junk, 1951.) 36 guilders.

PRIMARILY, this book is an investigation into the feeding patterns of leaf-mining insects and is the result of years of research by Prof. E. M. Hering on the leaf-mining habit. It is an attempt, based on the nature of the damage inflicted on the plant, which is in itself dependent upon the specific behaviour of the individual species, to identify, often down to species level, a diverse collection of insects.

The first chapter includes the definition and classification of the miners; each type of mine, which is well illustrated, is given a specific name depending upon its shape and form and the part of the plant where it is to be found. The following chapter deals with fundamental morphological characters which separate the four orders of insects—namely, the Lepidoptera, Coleoptera, Diptera and Hymenoptera—to which the leaf-mining habit is restricted. It also discusses the modifications in structure of the larvæ induced by the mining habit and emphasizes the disparities existing between mines caused by members of the different orders.

The author then considers the general life-history of mining insects, with much space devoted to the pupal stage, which tends to show greater variance between species, particularly concerning the selection of pupation sites. There is a tendency for leaf-mining insects to complete their life-history in a shorter time than that required by other phytophagous insects. Reasons for this, such as the consumption of highly nutritious food material and the uniformity of the micro-habitat, are dealt with in a separate chapter.

The extent of Prof. Hering's studies is indicated by the next chapter on disposal of frass, where he utilizes the types of frass deposition as a means of identification. In addition, the problem associated with the disposal of frass to prevent contamination of the mines is discussed.

The special adaptations of case-bearing miners and aquatic plant miners are considered individually. This is followed by a detailed account correlating mining habits with larval morphology, where the influence of environment on the development of the species is fully appreciated.

Associated with a chapter on host selection is a comprehensive list of plant families known to support a leaf-mining fauna. Opposite each family will be found the orders of insects recorded on them. The last part of the book covers the colour of the mines; the effect of mining on the growth of the plant; parasites, inquilines and symbionts; and, finally, a section on collecting, breeding and the difficulties in determination of the more difficult species.

This book contains a wealth of knowledge, the result of more than thirty years detailed study of the subject. It is well indexed, and the bibliography comprises nearly one hundred pages. The work makes interesting reading, the only marring feature being the unusual number of errata.

V. W. Fowler

## A PIONEER OF PLANT PATHOLOGY

### Erwin Frink Smith

A Story of North American Plant Pathology. By Andrew Denny Rodgers, III. (Memoirs of the American Philosophical Society, Vol. 31.) Pp. x+675+4 plates. (Philadelphia: American Philosophical Society, 1952.) 5 dollars.

Erwin Frink Smith (born in 1854), and from 1886 until his death in 1927 a scientist in the service of the United States Department of Agriculture, was not only the acknowledged 'dean of American plant pathology', but also a man of international reputation, whose pioneer work will always be remembered. In this considerable volume the author has produced an unusually well-documented biography of a great man. The story is simply told and the reader, almost unawares, finds himself living in that great period of botanical renaissance in Europe and of botanical exploration and discovery in the vast regions of the United States. On this period, Mr. A. D. Rodgers is particularly qualified to write. His first pictures of Erwin Smith are of a modest young man of unusual perceptiveness and competence, gradually finding his feet in science and in a philosophy of life, and enjoying in its manifold aspects the poetry of existence in a great and varied continent. Smith's inherent qualities were soon to become evident in an insatiable curiosity about the objects of Nature in general, and plants in particular, in a devotion to the precision of scientific methods, and an eye alert for innovations in ideas and techniques that would open up new high-roads in biology. Thus, a time came when his researches into fungal pathogens, and more especially into the quite new field of the bacterial diseases of plants, were to lead the world. These studies, which were characterized by great thoroughness and a mastery of illustration, have long occupied a fundamental place in this branch of biological science, and will continue to do so. He also made important contributions to our knowledge of plant viruses.

Although this book tells the life-story of a man, it also records the history of an unusually important period in biological and medical science, and in agricultural economy, both in the Old and New Worlds. Accordingly, this volume should prove of value as a source-book for information about the progress of pathology in general, as well as of Smith's own significant and numerous contributions. In this connexion it is probably a pity that in so extensive a book space was not found for a chronological list of Smith's papers and books. The book can also be recommended to all who like to read of lives well lived, and who wish to gain some insight into the springs of contemporary knowledge.

## OLD HAWAII

### Hawaiian Antiquities (Moolelo Hawaii)

By David Malo. Translated from the Hawaiian by Dr. Nathaniel B. Emerson, 1898. (Bernice P. Bishop Museum, Special Publication 2.) Second edition. Pp. xxii+278. (Honolulu: Bernice P. Bishop Museum, 1951.) n.p.

David Malo was a Hawaiian of good family, born about 1793, who spent his early life at court and became a great authority on native customs and traditions. When he came in contact with Christian civilization, he soon became an enthusiastic convert, and finally a Christian minister. He died in 1853.

His book "Hawaiian Antiquities" was written in the Hawaiian language, and the translation, with notes, by Dr. N. B. Emerson, edited by W. D. Alexander, was published by the Bishop Museum as long ago as 1903. It has long been out of print, and this second edition, which is little altered apart from improvements in format, has been issued in response to many requests.

The title of the book is misleading, since it is not an archæological treatise but rather an account of Hawaiian ethnology before contact with European civilization. It deals with many things, including customs, ceremonies, myths, traditions, the code of conduct, political organization, sports and material culture. Under the last-named heading are accounts of such matters as house building, furniture, food, bark cloth, stone adzes, canoes and articles of value, which will be particularly useful to those who have Hawaiian collections under their care. The few drawings which accompany these sections are probably Emerson's. Wherever appropriate, the native names of objects, ceremonies, etc., have been quoted in the translation, which therefore constitutes a kind of glossary of Hawaiian terms.

As a convert to Christianity and an admirer of Western civilization, Malo was bound to regard the old ways with disapproval, which comes out in such statements as "The newly imported articles are certainly superior to those of ancient times" and "Some of these miserable practices of the ancient Hawaiians were no doubt due to their devotion to worthless things"; but remarks of this kind are confined to a few lines at the ends of chapters, and most of the work seems purely objective. If he had known to what extent future generations would have to depend on writings such as this for information about his forbears, he would doubtless have dealt with many matters more fully than he did; nevertheless, we can learn a great deal from the book, and in the circumstances it is greatly to his credit.

G. H. S. Bushnell

## The Aphid Genus *Periphyllus*

A Systematic, Biological and Ecological Study. By Prof. E. O. Essig and Frieda Abernathy. Pp. ix+166. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1952.) 22*s*. 6*d*. net.

IN a family of insects remarkable for the variety of forms which may be assumed by a species during the course of a single life-cycle, the aphid genus *Periphyllus* van der Hoeven is peculiar in that most of its members produce, in addition, specialized æstivating larvæ which remain in the first instar from the spring until the autumn, when growth and development are resumed. The members of this genus are nearly all confined to trees of the maple family, on which they complete their life-cycles.

This book embodies the results of six years of study of a number of American species of *Periphyllus*, and includes descriptions of others from Europe and eastern Asia. In their accounts of species which they have been able to study at first hand, the authors have contributed materially to our knowledge of this group, and, with the aid of copious illustrations, have shown the remarkable degree of variation in form which can occur during the life-cycle of a single species. The inclusion of lists of synonyms, host plants, notes on history and distribution, together with an impressive bibliography, usefully brings together a quantity of relevant material within the compass of a single volume. But in their survey of the genus as a whole, it is disappointing that the authors appear to have overlooked some important contributions from European workers. There is no mention of the recent work of Borner, nor of Hille Ris Lambers's very full and detailed account of the known European species of *Periphyllus* (*Tijdschr. Ent.*, 88, 225; 1947).

In an otherwise attractively produced book, it is difficult to understand why most of the numerous line-drawings have been reproduced in half-tone, a process which, besides obscuring important anatomical details, does much less than justice to Frieda Abernathy's fine draughtsmanship. J. P. DONCASTER

## Amino Acids and Proteins

Theory, Methods, Application. Compiled and edited by Prof. David M. Greenberg. Pp. ix+950. (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, Ltd., 1951.) 110*s*. net.

THIS is an omnibus volume intended "to acquaint students and investigators with the more general methods employed in the study of the proteins, and to give a summary of the current knowledge and advances of the subject matter". Its aim is therefore nothing less than a comprehensive treatment of amino-acids and proteins from the physico-chemical, organic and biochemical points of view. There is, in fact, no marked emphasis on any particular aspect; there are four chapters on the organic chemistry of amino-acids and peptides, two on the organic chemistry of proteins, three on the physical chemistry, and four on biochemical topics. Most of the major lines of protein research are represented; there is, however, little about the determination of the sequence of amino-acids in proteins, and nothing about specific chain-configurations.

In a book of such scope, with a multiplicity of authors, it is almost inevitable that the treatment should be uneven and perhaps inadequate in parts. The accounts of paper chromatography and peptide synthesis are, for example, well below the average standard of the work. A rather more serious criticism is that the text is not always as up to date as one would wish. In my opinion the book does, however, succeed in bringing to the reader, in the form of a series of separate essays, a large amount of information, some of which is not readily available elsewhere. The numerous tabulations of data are a particularly praiseworthy feature. I have no doubt that students and investigators will find the book useful. It is very well produced, and contains remarkably few misprints.

C. H. BAMFORD

## Sound

An Advanced Course. By Dr. H. F. Boulind. Pp. vii+104. (London: John Murray, Ltd., 1952.) 6*s*.

IT is difficult to believe that a small book of a hundred pages on sound can cover adequately the required ground for all stages of the sixth form and up to university scholarship-level, no previous knowledge of the subject being assumed. This, however, is what is claimed for this book which, on the whole (and understandably in the circumstances), is rather utilitarian in its approach, with one eye constantly on the examination question.

One has a great deal of sympathy with the author in his admission that his chief aim is to produce a book at a cost within the financial allocation for sixth forms. But surely the correct approach is to supply a really satisfying account of the subject, especially in sound, which has for so long been neglected, and then press the authorities to bring the allocation more in accord with present prices. Sixth-form and scholarship students certainly need, and deserve to have, a full and comprehensive volume for their studies, and it is high time that this serious defect on the part of those responsible was rectified.

What is done in this book is, as is to be expected, done well. The mathematics is well within the scope of the students for whom the book is intended, and there is an excellent set of graded questions. It is a pity that a bigger quantity of information of the same high quality could not be included.

## Gods, Graves and Scholars

The Story of Archæology. By C. W. Ceram. Translated from the German by E. B. Garside. Pp. xii+433+32 plates. (London: Victor Gollancz, Ltd., in association with Sidgwick and Jackson, Ltd., 1952.) 21*s*. net.

THIS book is not intended for the specialist in prehistoric archæology; it is rather meant to fascinate the ordinary intelligent reader and to inspire him to delve more deeply into the subject. The author describes in graphic language the story of the discovery of several different sites in a number of localities; for example, he relates the earliest discovery of, and the first explorations at, such city sites as Pompeii, Troy, Mycenæ and Crete, and the origins of Egyptology. Again, the unearthing of Nineveh is recounted, as well as how the deciphering of Babylonian writings took place. The New World is not forgotten, and there is an exciting chapter on the empires of the Toltecs, the Aztecs and the Mayas. The historical approach to the subject is a good one and will undoubtedly excite many readers to dig more deeply into its problems, and the book can therefore be recommended. But even on the historical side it does not pretend to do more than dip into the subject here and there; it does not cover the ground as does such a work as Daniel's "Hundred Years of Archæology". None the less, it makes good reading. The translation runs smoothly. M. C. BURKITT

# BEHAVIOUR OF ENGINEERING STRUCTURES*

By Prof. A. J. S. PIPPARD, M.B.E.

Imperial College of Science and Technology, London

THE intelligent and economical design of engineering structures demands knowledge of their behaviour under load, and it is only in the light of this knowledge that the technical efficiency of a design can be assessed. It is, however, usually considered sufficient merely to estimate the distribution of stresses in a structure under normal load-conditions and to design to a factor of safety; while this will often produce a safe result, reliance upon such a simple method may very likely in special cases be either uneconomical or dangerous. In such cases detailed knowledge of stresses and displacements throughout the whole range of loading is desirable.

For idealized structures in which all the material and every member is assumed to obey Hooke's Law, the analysis of stresses and deformations is usually possible by well-known classical methods; but while over-simplification is tempting, it may well prove inadequate in many real structures, where practical factors complicate behaviour.

In many forms of construction one such factor is flexibility, which causes certain members to bow and even become unstable under load; the structure then behaves differently from the manner which would be forecast on the assumption of a linear load-displacement law. This form of elastic instability may occur, for example, in ship plating, which is thin in relation to its unsupported width, with the result that, while the distribution of tensile stress across the deck under a hogging bending-moment is reasonably uniform, the distribution of compressive stress under a sagging bending-moment is not. At the boundaries, where the deck is stabilized by the side plates, the stress is larger than that calculated by simple bending-theory, but at the centre it may drop to a very small value, in some cases almost to nothing. Instability in compression, by thus modifying the stress distribution deduced from the Bernoulli assumptions, may reduce the load-carrying capacity of the hull considerably.

Experiments carried out in the Civil Engineering Laboratories of the Imperial College of Science and Technology, London, on an idealized model of a hull illustrate this point, and a typical set of results are shown in Fig. 1.

Again, most constructional materials depart from Hooke's Law at stresses considerably below failure. In mild steel the breakdown of the linear relation between stress and strain is followed by yield during which strains increase greatly with no increase in stress. So long as the load on a structure is below that required to produce a stress causing yield in any member, the results obtained by classical mathematical methods will, in many instances, give excellent approximations both to stresses and displacements throughout the structure; but if this loading be exceeded, such calculations may be seriously in error.

For some years attention has been focused in a number of countries upon the problems of design introduced by a consideration of the phenomenon of plastic yield, with the object of basing the design of steel structures upon the ultimate load which they can carry rather than upon their behaviour in the elastic state. In Great Britain the lead in this work has been taken by Prof. J. F. Baker, of the University of Cambridge, and in the United States, where the method is known as 'limit-design', by Prof. W. Prager, of Brown University, and Prof. J. van der Broek, of the University of Michigan. More recently, a somewhat similar method for application to reinforced concrete frames has been developed by Prof. A. L. L. Baker, of the Imperial College of Science and Technology, London.

It may be remarked that there is nothing essentially new in the philosophy underlying these ideas, since for aeroplane frames ultimate strengths have always been adopted for specification purposes, and design based on a load factor has ensured a reasonable margin over normal flight conditions.

In the application of limit design to structures built of mild steel, however, the phenomenon of yield introduces the need for special treatment. When yield starts, the portion first affected can stretch considerably without carrying any more stress, and adjacent portions will have increased stresses thrown upon them. They in turn will yield, and ultimately the whole region will become plastic and form a hinge with a constant moment of resistance which can be calculated solely from the dimensions of the member. If such a hinge develops in a redundant structure and if the load on the structure be further increased, the bending moment at the plastic section will remain constant and further hinges will develop successively at other sections of the structure. When a sufficient number have formed, the structure will be statically determinate, and if loading is still further increased it will become a mechanism and collapse. It is evident that if the positions of all the plastic hinges can be foretold, the load required to cause this failure of the structure can be readily calculated.

It should be noted that with the development of each hinge the structure changes its character, and a simple parallel to this behaviour may be observed in a voussoir arch, a structure formed of a number of wedge-shaped blocks the mortar joints of which

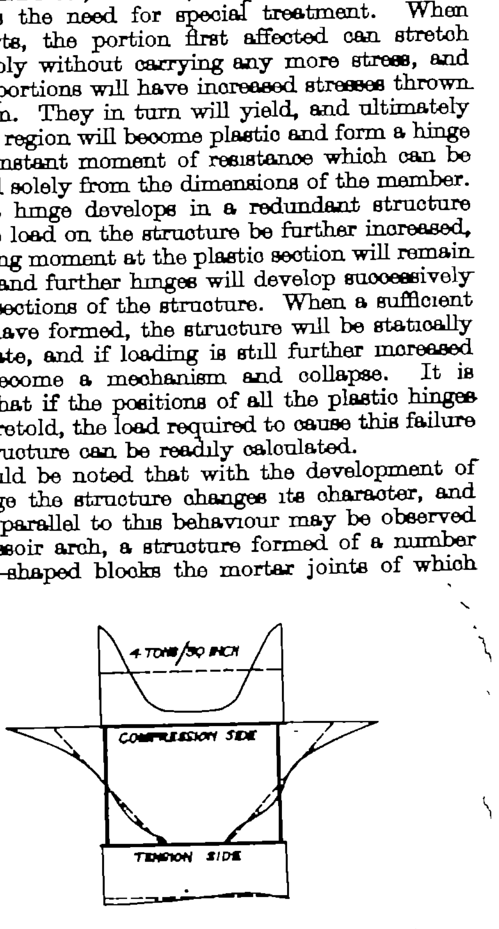

Fig. 1. Typical stress distribution around thin-walled box girders. The broken line shows the Bernoulli distribution

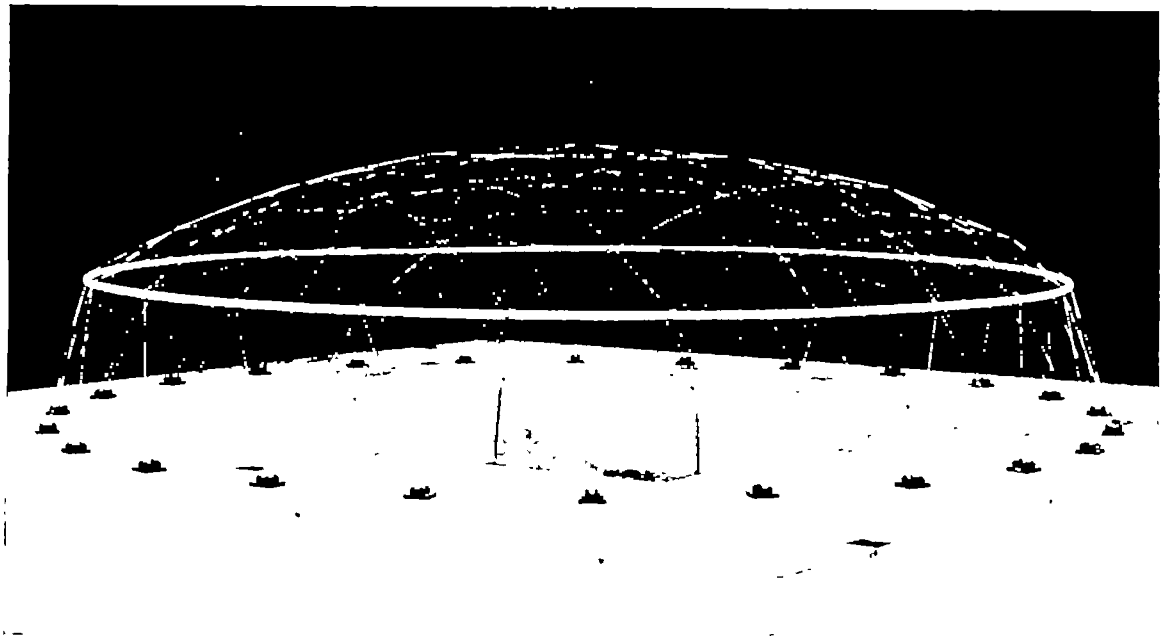

Fig. 2. Elastic model of the Dome of Discovery

are generally assumed to be incapable of resisting tensile stress. Under dead loading the arch behaves as a solid encastré rib, having three degrees of redundancy. If an increasing load be applied to any voussoir, the structure will continue to function as a solid rib up to a certain, calculable, value at which the loaded voussoir and that adjacent to it which is nearer the crown of the arch will make contact only along their edges on the outer boundary or extrados, and a virtual pin-joint will be established. The degree of redundancy is reduced to two, and, with further increases in the load, additional virtual pins will develop successively until the structure is effectively hinged not only near the load point but also at points on the inner boundary or intrados and at, or near, one springing of the arch. The structure is then statically determinate until the load is increased to a value which produces a fourth virtual pin at the other springing. It then becomes a mechanism, and its collapse, as shown in a film record of an experiment carried out on a model structure with steel voussoirs, is practically instantaneous[1]. We are concerned, then, not with a single arch but with four different arches each corresponding with a certain range of load carried. In a steel frame the number of effectively different structures may be much greater since the initial degree of redundancy can be very much higher. It is therefore a matter for discussion as to whether it is more rational to base a design on the particular structure which operates just before the failing load is reached, and which it is never expected even to approach, or upon that which does in fact carry the normal working loads. It is perfectly legitimate to adopt the former basis of design, and it will, in some cases at least, simplify calculations considerably; but the claim sometimes made that it produces economy in material does not appear yet to be established and must in any case depend upon the relative values of the load factor and factor of safety used in applying the two methods.

The logical position would appear to be to recognize that, unless we can calculate the failing load of a structure, there will always be uncertainty as to what working stresses we may justifiably use. The more we know about the behaviour of a structure, both in the elastic and plastic phases, the surer will be our position in the effort to achieve economy. It may be hoped, therefore, that we shall not see the growth of two rival schools of thought, the 'elastics' who see no good in the new approach and the 'plastics' who profess to believe that a new era in engineering has dawned in which the classical methods will find no place. Such a dichotomy might easily result in well-proved methods sinking into disrepute on one side, and first-class research being neglected on the other. There should, in fact, be no fundamental antagonism between the two points of view; each concerns itself with the behaviour of structures under certain defined conditions, but both are necessary for proper understanding. Surely the approach to design should be neither exclusively plastic nor elastic but 'elasto-plastic'.

Our present knowledge of structural theory is the sum of mathematical speculation, during a period of two or three hundred years, of many experiments made in the laboratory, of a comparatively few full-scale tests and lastly, but very important, of observed structural behaviour, especially in accidental failures.

The development of elastic theory has been dealt with at length in many publications, and it is unnecessary, and indeed impossible, to traverse the ground in a short article.

As an example of the lessons to be learnt from accidents, the failure of the Tacoma suspension-bridge may be cited[2]. Soon after its completion, this bridge developed a tendency to oscillate in a wind, and was in consequence subjected to continuous close observation. After it had been in service about five months, a steady 40-m.p.h. wind set up a violent motion which grew steadily worse; longitudinal and torsional oscillations increased in amplitude, and within a short time the whole structure collapsed. Cinematograph records throughout the final stages furnished a complete story of the disaster, and

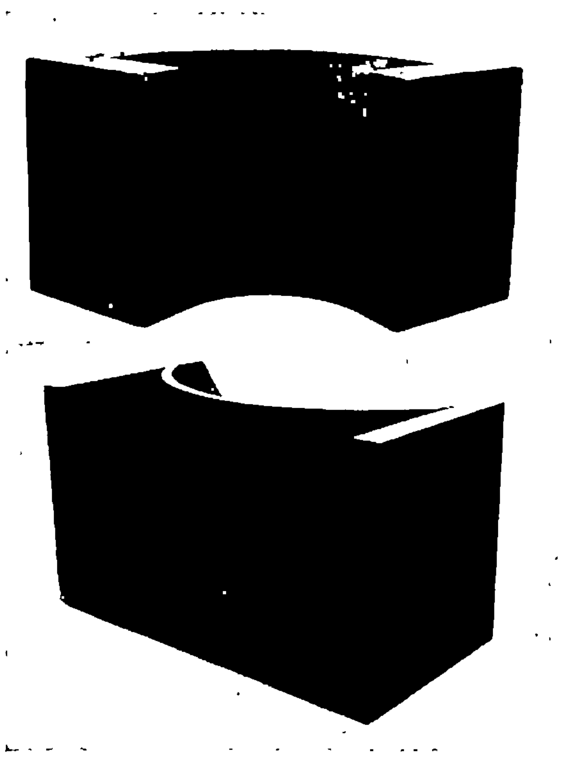

Fig. 3. Models of arched dams in indiarubber

mathematical and experimental study showed it to be due to the aerodynamic phenomenon of flutter which had hitherto been associated only with aeroplane wings and control surfaces. This disaster, although tragic in itself, served to attract attention to vital points in design which up to then were unsuspected as potential sources of danger, and no designer would now consider building a large suspension-bridge without making a very full investigation into its aerodynamic properties. As a case in point, the design for the proposed Severn Bridge has been subjected to exhaustive wind-tunnel tests under the direction of Dr. R. A. Fraser, of the Aerodynamics Division of the National Physical Laboratory, Teddington.

Learning from accidents is, however, expensive and uncertain, and, just as there are ways of roasting pig cheaper than burning down the house, so there are other methods of studying structural behaviour. The development of research into plastic behaviour, partly mathematical and partly experimental, has already been mentioned. A new and powerful analytical weapon has been provided by Sir Richard Southwell, who has devised the relaxation process which enables numerical answers to be obtained for a wide range of problems which are difficult or even intractable by classical methods.

The development of laboratory techniques for the study of structural behaviour is comparatively modern. Some of these are so simple that it is now fairly common, for example, to find experimental stress analysis by celluloid models carried out in the offices of practising engineers either as a sole method or in conjunction with calculation. This, based on Clerk Maxwell's reciprocal theorem, is an indirect method—that is, it requires no direct measurement of stresses; these are inferred from a comparison of measured displacements. A recent extension of the method[3] has been a study by means of an elastic model of the stresses in the Dome of Discovery of the Festival Exhibition, London (shown in Fig. 2). The experimental results were very good compared with those found by a relaxation process and indicate that space as well as plane frames can be reliably analysed in this way.

Photoelastic investigations are proving valuable in plane and three-dimensional stress problems, and considerable use is being made of electric-resistance strain gauges to obtain complete pictures of stress distribution in a variety of structures. One such investigation has already been mentioned, and the curves of Fig. 1 give an idea of the possibilities opened by this post-war technique.

In 1907 Wilson and Gore[4] used rubber models to study the stresses in gravity dams, but it was not until 1947 that Zienkiewicz[5], using relaxation methods, provided exact theoretical solutions. The agreement in the patterns of distribution obtained was very good[6].

The study of dams by models has hitherto presented certain difficulties, one of which has been to reproduce pressure and gravity loading in the right proportion. This has usually been met by using mechanical loading to represent both systems.

Another difficulty has been to obtain material which could be formed to the correct shape, which satisfied Hooke's Law and which was sufficiently flexible to give displacements large enough for accurate measurement. Rubber Technical Developments, Ltd., of Welwyn Garden City, by a newly developed technique, have produced excellent pilot

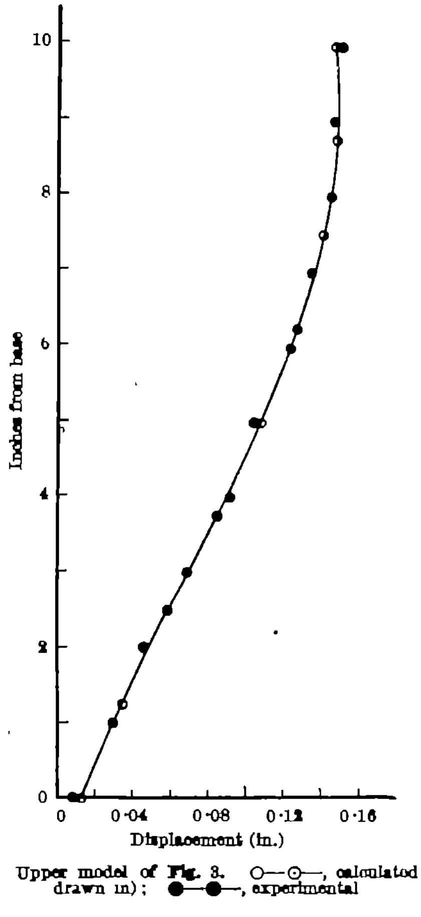

Fig. 4. Upper model of Fig. 3. ○—○—, calculated (curve drawn in); ●—●—, experimental

models of arched dams in suitable material having a Young's modulus of about 120 lb./sq. in., and these are shown in Fig. 3. Fig. 4 shows the measured deflexions of the centre line of the first model due to water pressure, compared with those calculated by relaxation methods. A much larger model of a projected dam has now been successfully moulded, and an extensive programme of research started in the Civil Engineering Laboratories of the Imperial College.

To determine gravity stresses at any point on the surface of the dam, the strains produced when the model is turned upside down will be measured; these will be twice those due to gravity loading, and the stresses deduced from them, when multiplied by the scale factor and by the ratio of the densities of the prototype and the model, will give the gravity stresses in the real dam. The full-scale stresses deduced from strains in the model due to water pressure alone can then be added.

The objective of the engineer in actual construction, and the crucial test of the value of calculation or research will always be the extent to which it helps to give a true idea of the behaviour of real structures. More full-scale tests for comparison with the results obtained by calculation or experiment are consequently vital if progress in structural engineering is to continue, and arrangements are being made by the Institution of Civil Engineers for a conference on this subject in 1955. Any engineer who is in a position to contribute records of results obtained from actual stress or displacement measurements on real structures, especially if correlated with calculations or tests, is invited to communicate with the Secretary of the Institution so that tests can be co-ordinated to yield the maximum amount of information.

# SULPHATES IN AFRICAN INLAND WATERS

## By R. S. A. BEAUCHAMP

East African Fisheries Research Organization, Jinja, Uganda

THE larger African lakes receive from their inflows small amounts of water relative to their volume, and these inflows usually contain inconsiderable amounts of sulphate. Data from Lake Tanganyika[1] show how sulphates are being removed from solution. The outflow from this lake is small and at times, when the lake-level is low, no water flows out of the lake. Consequently, one might expect the values for most dissolved salts in this lake to be higher than the mean values for these substances in the inflows. This is in fact so for sodium, potassium, chloride and phosphate, being three or more times the values obtaining in the inflows; but the concentration of sulphates in the lake is less than half the mean concentration contained in the inflows.

In any lake a shortage of sulphates may arise unless adequate amounts are supplied by inflowing streams, as the balance of biological processes acts in such a way that sulphates in solution are utilized and precipitated faster than they are released by the decomposition of organic matter. The main loss of sulphates is brought about by protein synthesis and the subsequent precipitation of this organic matter, both vegetable and animal, on to the bottom. Decomposition of this organic matter usually occurs under anaerobic conditions leading to the formation of hydrogen sulphide and insoluble sulphides. Sulphates may also be reduced directly by bacterial action to sulphides. Once they have been reduced, either directly or indirectly, to metallic sulphides in the mud, and then overlaid by further deposits, little of this sulphur is recovered and put back into circulation. On the other hand, sulphates are returned to the water when organic matter is decomposed aerobically; however, in most lakes there is usually less opportunity for aerobic decomposition than there is for anaerobic decomposition, and not all the organic matter which is decomposed aerobically is broken down completely. Thus, on balance, the biological processes occurring in lakes cause a continuous removal of sulphates from solution. This is a matter of little consequence in lakes which are fed by inflows containing amounts of sulphate sufficient to maintain an adequate supply.

Though Lake Tanganyika has been used for illustrating the contention that sulphates are continually being removed, it does not show how far this process may be carried, probably because biological activity is limited in this lake by marked thermal stratification. The waters of Lake Tanganyika[2] contain about four parts of sulphate per million, but many of the African lakes contain less. In some of these it seems that sulphate deficiency may be a factor affecting the growth of phytoplankton. The following values as parts per million have been recorded:

| | |
|---|---|
| Lake Rukwa[2] | 2·9 |
| Lake Bangweulu[3] | 2·3 |
| Lake Albert[4] | < 2·0 |
| Lake Victoria[4–6] | 0·8–1·8 |
| Lake Mweru[7] | "traces indosable" |
| Lake George[4] | < 0·5 |

The last lake is not infertile or unproductive, it is probably the most fertile lake in East Africa; but clearly there are occasions when the available sulphates are reduced by the phytoplankton to a very low value. Data collected suggest that sulphates may be a factor controlling the level of productivity both in Lake Victoria and in Lake George.

The small amount of sulphate in solution in Lake Victoria appears to be restricting the growth of the phytoplankton, judging by experiments with algal cultures at present in progress. It is hoped that the results of these experiments, which are being carried out in this laboratory, will be ready for publication shortly; they indicate that values for sulphate below 0·5 p.p.m. are too low for algal growth. These results are surprising when one considers that phosphorus, which occurs in algae in about the same amount as sulphur, is absorbed from water containing concentrations of phosphate so low as one part per hundred million or less. It is, of course, extremely difficult to make a really close assessment of the value at which a particular chemical substance becomes limiting in any particular lake. This is especially so under tropical conditions where in the absence of a marked seasonal cycle the release of nutrients and their utilization is a more or less continuous process, except in such lakes as Tanganyika, Nyasa, Edward, and parts of Lake Victoria, where periodic thermal stratification leads to interruptions in the growth of the phytoplankton.

Lake George was described as probably the most fertile lake in East Africa: it supports a dense phytoplankton and a very large population of fish; yet sulphates, which are essential for plant growth, are not detectable in solution in the water. This statement invites consideration of the question: What determines productivity in tropical lakes? It may be assumed that light and heat are not limiting factors. It seems that in the shallower tropical lakes, such as Lake George, which have a free circulation between surface and bottom water, the level of production must be determined by the rate at which nutrient salts can be taken up, turned into organic matter, both vegetable and animal, and then decomposed to provide nutrient salts again. If this cycle is completed rapidly, production will be high; if slowly, production over a given period will be low. Our observations indicate that the slower processes in this cycle, and therefore the ones controlling its rate, are those concerned with the decomposition of organic matter, particularly matter of vegetable origin. Thus anything tending to increase the rate of decomposition will accelerate the whole biological cycle and increase productivity. The part played by animals in determining the rate of this cycle is certainly considerable, as animal matter decomposes rapidly, whereas plant matter decomposes slowly. Animals also during their lifetime are continually breaking down organic matter and fertilizing the water with their excreta, both fæcal and urinary[9]. Urinary excretions may be of particular significance with regard to the release of sulphates. Thus up to a point the more herbivorous animals in a tropical lake, whether they be copepods, fish or hippopotami, the faster the biological cycle and the higher its fertility and the greater the density of fish it can support. This theory contrasts strongly with ideas derived from the study of temperate lakes and may have an important bearing on problems concerning the overfishing of tropical lakes, particularly those where the industry is based on herbivorous fish such as *Tilapia*, which feed directly on the phytoplankton. Apart from these considerations regarding the way the fauna may affect the rate of production in a lake, productivity is also determined by the total amount of nutrients in circulation.

Sulphur is essential to living organisms, as all proteins contain this element; but it has not received as much consideration by either hydrobiologists or agriculturists as either nitrogen or phosphorus, as in most parts of the world sulphates occur in considerable quantities in both inland waters and the soil. In many parts of Africa this would seem not to be so. Unpublished records of water analyses made by government chemists and public analysts have been collected from rivers, streams and boreholes in different parts of Africa, including Nigeria, the Belgian Congo, Northern and Southern Rhodesia and Natal, as well as from East Africa. Unfortunately, in many cases no estimates have been made for sulphates, but in a great many cases where they have, the values recorded are low; often they are referred to as nil or negligible. This naturally raises the question whether or not the soils of Africa are short of sulphates; requests for information to the various agricultural departments have yielded little positive information, as estimations for sulphates are not usually included in routine analyses. However, P. R. Hesse, a member of the East African Agriculture and Forestry Research Organization, who is working on the effect of termites on the soil, has determined the sulphate content of a great many soils in Northern and Central Tanganyika, the Eastern Rift Valley in Kenya, also near Kisumu, and at Kawanda and Jinja in Uganda. These analyses were carried out in order to compare the chemical composition of the surrounding soils with that of the termite mounds. His results are not yet published, but in all the areas quoted only traces of soluble sulphates were found.

The red upland soils in the Kongwa area were found to contain no soluble sulphates; these analyses were done by B. Anderson. High values for sulphates were found, however, in the grey mbuga clays in the same area—these will be referred to later.

Certain soils in Nyasaland[9] were found to be deficient in sulphates; this deficiency had a serious effect on the tea crop.

Fertilization experiments carried out by agriculturists with the intention of discovering the value of adding nitrogen to the soil have shown excellent results in many parts of East Africa, but the fertilizer used for this purpose has been ammonium sulphate; it is possible that the sulphate radicle has played a part in giving these good results. In other fertilization experiments using superphosphates, it is possible that in some cases beneficial results have been partly due to the presence of calcium sulphate contained in this fertilizer; superphosphates[10] may contain up to 20 per cent of calcium sulphate.

Many more data are required, but there are indications that at least some African soils are deficient in sulphates; apart from the work done on the Nyasaland tea crop, there appear to be no other records of experimental work specifically designed to show this. It would be interesting to know whether in certain areas the addition of sulphates, such as calcium or sodium sulphate, can increase the growth of crops. One record of such an experiment[11] comes from the Gezira, Sudan, where the application of two tons of gypsum per feddan increased the yield of cotton by more than thirty per cent; but this experiment was carried out with the idea that gypsum would improve the texture of the soil and the results were attributed to this effect, as in this region sulphates do occur in considerable amounts in the subsoil.

Brief reference should be made to those waters in Africa in which sulphates have been found in both moderate and large amounts. The streams on Mount Meru[12], Tanganyika Territory, can be divided into two groups—those originating from the less-weathered rocks and those from the more-weathered rocks; the former have a sulphate content of less than ten parts per million, the latter a sulphate content of between twenty to sixty parts per million. Three streams contain more than one hundred parts per million of sulphates. Mount Meru is composed of igneous rocks and lavas.

The soda lakes of the Eastern Rift Valley form a series in which the sulphate content is high, culminating in Lake Nakuru[13], with a value of two hundred and fifty-three parts per million, and Lake Magadi, which is the extreme example but is usually dry. The sulphates in these lakes may not have been utilized fully and precipitated biologically, because the high soda content has restricted the growth of both flora and fauna. The drainage basins of these lakes contain alluvial deposits formed by lakes which existed earlier; at the present time these lakes have no outlet, and thus their chemical content is the result of the leaching of the surrounding soil and the concentrating of their inflows over a long period of time. Lakes Naivasha and Baringo[13] contain seventeen and forty parts per million, respectively.

The grey mbuga clays in the Kongwa area, referred to earlier, have high sulphate values. Mbuga is the local name for low-lying depressions in the ground which in the past probably contained lakes. These depressions have accumulated salts leached from the surrounding countryside. Borehole waters in this area contain very large amounts of sulphate, ranging from one hundred parts per million to two thousand parts per million.

Hot springs may contain large amounts of sodium and calcium sulphate; one in Northern Rhodesia[14] contains one thousand and fifty parts per million, another in Uganda[4] contains approximately five thousand parts per million. The Northern Rhodesian spring contains ninety parts per million of calcium, whereas the Uganda spring contains two thousand parts per million of calcium. As this spring flows into the Semliki River, and so into Lake Albert, it and other springs in the neighbourhood may be responsible for the relatively high value for calcium in this lake. At the same time, it is worth noting that, as recorded above, the value for sulphates in Lake Albert have been found to be less than two parts per million, indicating that most of the sulphate that finds its way into the lake is used up.

Some swamps in the Kigezi district[15] of Uganda contain very large quantities of ferrous sulphate; these may receive water from some volcanic source.

Streams contaminated by washings from dumps formed by concerns smelting copper are rich in sulphates. Examples of these from Northern Rhodesia[14] show values for sulphate ranging between four hundred and seven hundred and eighty parts per million, whereas streams near by are recorded as containing no sulphate. The refining process of copper is usually carried out by calcining the copper sulphide ore with lime; the waste product formed is mainly calcium sulphate. This by-product may prove to be a valuable fertilizer for fish farms and possibly for agricultural purposes. In this connexion it is worth recording that the smelters also discharge vast quantities of sulphur dioxide from their chimney-stacks. The safe disposal of this gas presents some problems as it is not in Africa an economic proposition to convert all this sulphur dioxide into sulphuric acid, although this acid is in great demand in other parts of the world. Greater demands for sulphuric acid may soon arise in East Africa, including the need to produce superphosphates from rock phosphate. A by-product of this process is again calcium sulphate.

One generalization may perhaps be permissible in order to explain the apparent shortage of sulphates in Africa. In other parts of the world sulphates are usually derived from sedimentary rocks, mostly ancient marine deposits; such rocks are rarely found in Africa. The fact that the only sources of gypsum in East Africa are those contained in the cretaceous deposits along the coast of Tanganyika Territory may serve to emphasize the point.

More data are required; but the evidence we have at present indicates that many of the natural waters of Africa are short of sulphates, and some of the soils also. The main purpose of publishing this account is to arouse interest in what may be a most important problem, not only to those concerned with inland fisheries but also to those concerned with agriculture and animal husbandry.

# THE FIFTH PAKISTAN SCIENCE CONFERENCE AND THE PAKISTAN ACADEMY OF SCIENCE

By SIR HAROLD HARTLEY, K.C.V.O., C.B.E., F.R.S.

IN February Dr. George Taylor and I, representing the British Association, were the guests of the Pakistan Association for the Advancement of Science for its Fifth Science Conference at Lahore, and for a study tour of Pakistan. The Conference was opened by the Governor of the Punjab, who spoke of the progress that had already been made in the Punjab both in strengthening scientific education and in establishing a number of research laboratories which are attacking urgent problems such as water-logging and the salinity of agricultural land. He spoke of the need of Pakistan, an under-developed country, for scientists and engineers, and the help that international co-operation would bring. The president, Dr. Bashir Ahmad, vice-chancellor of the University of the Punjab, took as the subject of his address "Our Problems of Higher Education and Science". His main theme was the position of science in general education not merely for its material benefits but also for its unique function in guiding sound emotional development. Science, he said, is the systematic knowledge of Nature and her ways. That knowledge has cultural value which is as significant as that of philosophy, fine arts or literature. He made a strong plea that science should be a compulsory subject in the school curriculum. He emphasized the need of Pakistan for institutions of higher learning and science, which must remain free from political control in order to achieve their objectives.

The work of the Conference was done mostly in eight sections covering the main branches of science, engineering, agriculture and medicine. Many papers were read describing recent research work in universities and research laboratories in both Western and Eastern Pakistan. Most of them dealt with applied science, and they showed what a realistic and successful contribution is being made to national development, particularly in agriculture, genetics, entomology, chemistry and economics.

In addition there were a number of general lectures; for example, by Prof. H. J. Bhabha, director of the Tata Institute of Fundamental Research, on cosmic rays, by Dr. Taylor on south-east Tibet and on the work of the British Museum, and by myself on the art of discovery and on limiting factors in production.

The Conference was extremely successful. Large numbers of young students came to the meetings and were obviously keenly interested in the papers. Both during the meeting and after its close, the twenty-five foreign delegates were able to visit a number of research laboratories, including Dr. Chaudhury's new nuclear physics institute at the Government College, Lahore, which will be finished shortly, and the Punjab Agricultural College and Research Institute at Lyallpur, where a large programme of research is in full swing. It covers the main agricultural problems of Western Pakistan and much progress has been made in improving the strains and the methods of cultivation of the staple crops.

We then motored to Peshawar, where we saw the University and the fine engineering laboratory which will soon be completed. We visited the Khyber Pass, the Malakand and Dargai power stations, and the site of the hydro-electric scheme on the Kabul River at Warsak which will produce both cheap electric power and irrigate some 65,000 acres of land on the North-West Frontier, making it available for cultivation by the frontier tribes. Financial assistance from Canada under the Colombo Plan will enable work on this site to start at once.

We were greatly impressed by the progress which is being made in the North-West Frontier Province under the dynamic leadership of the Chief Minister, Abdul Qayum, in education, hospitals, rural electrification and factories for the processing of agricultural products, like the sugar refinery at Bialpur. We went next to Rawalpindi to see the hill station at Murree, the Himalayan forest, and the ruined city of Taxila, with its fine Romano-Buddhist museum under the curatorship of Mr. Harundur Rashid.

In Karachi we saw the new University in its improvised home, the laboratories of the Department of Scientific and Industrial Research, where important researches have already started without waiting for full equipment, the Central Testing Laboratory, and the Cotton Research Institute. During our visit we were impressed by the excellent work which is being done in various centres by the British Council.

The most urgent problems of Pakistan, apart from her food shortage, seem to be supplies of irrigation water, drainage and electric power. These are all inter-connected, and it is to be hoped that the negotiations with the World Bank will soon result in engineering works for the control of the headwaters of the Indus, which could provide both perennial irrigation and ample power. The experience of irrigated zones in Egypt and Arizona suggests, however, that the problem of the salting up of the soil, which is becoming increasingly serious, will only be met by extensive drainage systems.

### The Pakistan Academy of Sciences

In the afternoon of the first day of the Conference, February 16, we were present at the inauguration of the Pakistan Academy of Sciences, by the Prime Minister of Pakistan, Al-Haj Kwaja Nazimuddin. He spoke of the heritage of scientific and cultural achievement in Muslim history and of the dark Middle Ages of the West, when Muslim scientists kept the spirit of scientific inquiry alive. The Government recognizes, he said, the importance of pure scientific research as the bed-rock of all important forms of development, and it welcomes the establishment of the Academy, which was destined to play a vital part in the life of the nation.

The nine Foundation Fellows of the Academy were then presented to the Prime Minister, and they later elected the following office-bearers: *President*, Prof. M. Afzal Husain, formerly vice-chancellor of the University of the Punjab; *Secretary*, Prof. M. Raziuddin Siddiqui, director of research, University of Peshawar; *Treasurer*, Dr. Bashir Ahmad, vice-chancellor of the University of the Punjab. The other Foundation Fellows are: Dr. Nazir Ahmad, chairman, Tariff Commission, Pakistan Government; Dr. S. Siddiqui, director, Scientific and Industrial Research, Pakistan Government; Dr. M. Qudrat-i-khuda, scientific adviser, Ministry of Defence, Pakistan Government; Dr. M. Ishaq, principal education officer, Pakistan Military Academy; Dr. H. K. Bhatti, chairman, Department of Zoology, University of the Punjab; and Dr. M. Sharif, professor of zoology, Government College, Lahore.

The aims and objects of the Academy had been defined as the promotion of research in pure and applied sciences by means of publications, by the establishment of scientific libraries, laboratories, museums and research institutions, and by awarding grants, scholarships, fellowships, prizes and medals for research. The Academy will act as the National Research Council of Pakistan, for undertaking such scientific work of national or international importance as it may be called on to perform by the public and the Government. It will offer advice on all scientific matters to the Government and will represent internationally the scientific work of Pakistan.

Not more than five ordinary Fellows, distinguished for their original contributions to science, will be elected into the Academy each year until the limit of a hundred is reached. Eminent scientists of foreign countries will be elected as foreign members. These will be limited to thirty in number.

The Academy has already started work and plans are being prepared for the publication of *Proceedings* and research journals.

## OBITUARIES

### Prof. S. N. Winogradsky, For.Mem.R.S.

With the death on February 24 of Sergei Nikolaevitch Winogradsky, science has lost the greatest figure in soil microbiology. Winogradsky was born in Kiev in 1856 and spent his childhood there. He was a student in the University of Kiev and, later, that of St. Petersburg, where he studied chemistry and plant physiology. There, after graduation in 1881, he investigated the effects of nutrient supply and other environmental factors on the growth of the wine yeast *Mycoderma*.

This early work was one of the pioneer investigations on the effects of specific nutrients on micro-organisms grown in pure culture under adequately controlled conditions. In 1885, Winogradsky moved to the University of Strassburg, where he became interested in micro-organisms concerned with the oxidation of sulphur and sulphides. He found that *Beggiatoa* was able to assimilate carbon dioxide, obtaining the necessary energy by oxidation of sulphur. This discovery started him on the classic series of investigations concerning autotrophic bacteria which opened up one of the most interesting fields in bacterial nutrition. He next passed to the study of the iron bacteria, some of which he claimed could similarly derive energy by the oxidation of ferrous iron.

Winogradsky went to Zurich in 1888 and in the following year began research on the problem of nitrification, that is, the oxidation of ammonium salts to nitrate. The importance of this process had already resulted in a search for the causative agents, and there was evidence that the process proceeded in two stages with the formation of nitrite and nitrate, and that the causative agents were biological. But attempts to isolate the responsible organisms had been unsuccessful. Winogradsky, with his experience of sulphur-oxidizing organisms, divined that those causing nitrification were also autotrophic, and he therefore used for their isolation an inorganic medium with a base of silica jelly. By this means he obtained two groups of autotrophic bacteria, one able to oxidize ammonium salts to nitrite and the other nitrite to nitrate. His investigation of the physiology of these organisms constitutes one of the classic researches in bacteriology. In 1891 Winogradsky returned to St. Petersburg, where he was appointed chief of the Division of General Microbiology at the Institute of Experimental Medicine. There he began work on a second soil process of fundamental importance in the economy of Nature, the fixation of atmospheric nitrogen. When he began this investigation, Hellriegel and Wilfarth had recently demonstrated symbiotic nitrogen fixation in the nodules produced by bacteria on the roots of leguminous plants. Winogradsky studied the gains in nitrogen of soil and showed the existence in it of an anaerobic organism, *Clostridium pastorianum*, that was capable of fixing nitrogen. This was the first non-symbiotic organism shown to possess this ability.

In 1905, after a period of ill-health, Winogradsky retired from scientific work and lived on his estate in Russia until 1921, when he finally left the country and, after a short stay in Switzerland, accepted the offer by the Institut Pasteur of a post and a laboratory at Brie Comte Robert, about twenty miles from Paris. During this phase of his work, he was much concerned with the difficulty in studying the micropopulation as it actually exists in the soil. He pointed out that most of the methods that were in common use consisted in isolating a number of organisms from soil and studying their behaviour under the unnatural conditions of the laboratory. He therefore devised methods for the purpose of investigating the micropopulation in the soil itself. In the first place, he developed and used a technique previously tried by H. J. Conn, namely, the microscopic examination of a film of soil suspension, dried and suitably stained to reveal the micro-organisms. Samples of soil with and without the previous addition of organic matter were thus examined. Winogradsky concluded from these observations that untreated soil contained a static micropopulation, but that the addition of decomposable nutrients caused the rapid increase in numbers of certain groups of organisms, the soil then passing from the static to the dynamic condition. A special example of this differential increase, that of *Azotobacter* in soil enriched with mannitol or starch, was investigated. This led to the invention of a method for detecting phosphate deficiency in soil, by observing the growth of *Azotobacter* colonies on the smoothed surface of a soil sample wetted to a thick paste after the addition of starch.

Another method developed by Winogradsky was that of sprinkling fine granules of soil on the surface of silica gel plates to which a specific nutrient had been added. He used this method for studying the development of colonies of *Azotobacter* arising from the soil granules. Later the method was used, with appropriate media, to obtain nitrifying organisms from soil. In the course of this further study of nitrifying organisms, several new genera were described. By similar methods, Winogradsky also studied aerobic soil organisms that attack cellulose, and made a special study of the Myxobacteria possessing this power, for which he proposed the generic name *Cytophaga*.

But his work at Brie Comte Robert, while yielding valuable new information on interesting groups of soil organisms, owes its main importance to his individual approach to the subject and to his constant aim at discovering what organisms were active in the soil itself and what were the conditions governing their activity therein. The methods that he developed all had this object in view. Indeed, throughout his life's work, Winogradsky showed an unequalled ability to devise experimental methods of elegant simplicity, but directly suited to the problem under investigation. This ability, together with the clarity of thought which characterized his work, enabled him to discover and develop new fields in bacterial physiology, particularly relating to specialized organisms of the greatest importance in the economy of Nature, and later on to change and enlarge our views on the ecology of the soil micropopulation.

H. G. THORNTON

## Prof. R. D. Laurie

ROBERT DOUGLAS LAURIE, whose death occurred on April 7, was born in 1874; he was educated at Birkenhead School. After a period on the staff of the Bank of Liverpool (1891–99), he studied in the Universities of Liverpool and Oxford, and was afterwards appointed to the staffs of the Zoology Department first of the latter and afterwards of the former. He remained at Liverpool for some years; but in 1918 he was appointed head of the Zoology Department in the University College of Wales, Aberystwyth, and was given professorial status four years later. He remained at Aberystwyth until his retirement in 1940.

Laurie's scientific work was of two main types. He published systematic reports on some Brachyura collected by Herdman in Ceylon in 1902 (Ceylon Pearl Oyster Fisheries Reports, 1906) and on the Anomura of Stanley Gardiner's *Sealark* Expedition (1926). After his appointment at Aberystwyth he took a keen interest in local problems of natural history—especially in the bottom-fauna of Cardigan Bay, and in the effects of pollution of certain Welsh rivers by lead. In collaboration with various colleagues he produced a number of reports on these subjects, notably a paper (with Erichsen Jones) on the faunistic recovery of the Rheidol after lead-pollution (*Journal of Animal Ecology*, 1938).

As a professor, Laurie was genial, imperturbable, persistent in the face of difficulties, and regarded with sincere affection by students and colleagues. His personal characteristics—he was like a cheerful robin—gave rise to a whole series of tales (true and legendary) which in time constituted a veritable collection of affectionate 'Lauriana'. His unflagging attempts to develop his department, including a phase during which he and his students built a lecture-room with their own hands, were prevented by fate and the Second World War from reaching full fruition by the time of his retirement.

It was not, however, Laurie's activities as a zoologist or as a professor which will be remembered as his leading contribution to the welfare of his subject or his colleagues. The outstanding interest of his later years, and his chief service, lay in the field of organizations designed to promote the interests of university teachers and of university and educational affairs in general. It was Laurie's unfailing zeal, more than that of any other single person, which brought into existence the Association of University Teachers. He was its first president, in 1919, and was its honorary general secretary from 1920 to the time of his death. In addition (1943–53) he was honorary secretary-general to the International Association of University Professors and Lecturers, and it was at a conference of this organization that he died, after flying to Amsterdam, at the age of seventy-eight. Much of the credit for the achievements of these organizations may be traced back to Laurie's energy and enthusiasm. His educational interests were revealed in other ways, as in his reports for a British Association committee on the position of animal biology in the school curriculum; and he was responsible for the introduction of biological teaching in the grammar schools of Wales.

Laurie married Elinor Beatrice Ord in 1912, and both she and his daughter survive him. Mrs. Laurie has also for many years been beloved, not only by her family, but also in no common degree by her many friends, including those connected with her husband's enterprises. T. A. Stephenson

## Dr. T. A. Jaggar

Dr. T. A. Jaggar, dean of American volcanologists, died in Honolulu on January 17, just one week before his eighty-second birthday. Born in Philadelphia, Pennsylvania, on January 24, 1871, Thomas Augustus Jaggar, jun., was trained in public and private schools, and in 1893 received the degree of bachelor of arts in geology from Harvard University. He remained at Harvard to take his M.A. degree in 1894, and then spent most of the next two years studying at Munich and Heidelberg. Returning to Harvard, he was awarded the doctorate of philosophy in 1897.

During 1895–1903, Jaggar held an appointment as instructor in geology at Harvard, and in 1903 he was made an assistant professor. In 1906 he became professor and head of the Department of Geology at the Massachusetts Institute of Technology. During the summers he was a member of the United States Geological Survey, working in the Black Hills region of South Dakota and adjacent parts of Wyoming, in the Yellowstone National Park region, and in Arizona. In 1901 he published, in the Annual Report of the Geological Survey, an important study of the laccoliths of the Black Hills.

Very early, Dr. Jaggar's interest turned to experimental geology, and the study of earth processes in the field. His visit to Martinique in 1902, to study the results of the catastrophic eruption of Mont Pelée, decided him to adopt as his life-work the field-study of geophysics. From that time forward his major interest lay in the fields of seismology and volcanology, with a strong emphasis on the humanitarian aspects of both. His aim was the saving of human lives and property through the prediction of earthquakes and volcanic eruptions, the design of suitably resistant structures for countries subject to frequent earthquakes, and development of methods of protecting communities from the ravages of lava flows, glowing clouds, and heavy ash falls. Although he took part in many expeditions, Jaggar was firmly convinced that the only satisfactory way of studying volcanoes was by means of permanent observatories, keeping continuous records.

In 1912, Dr. Jaggar established the Hawaiian Volcano Observatory, for the continuous study, by direct physical methods, of Kilauea and Mauna Loa volcanoes. This was made possible by money provided from the Whitney Fund of the Massachusetts Institute of Technology, and funds subscribed by a group of business and political leaders of Hawaii that had formed the Hawaiian Volcano Research Association. For more than forty years the Hawaiian Observatory has carried on its work, under the Massachusetts Institute of Technology and later under successive agencies of the United States government. Dr. Jaggar remained its director until his retirement, in 1940. He then became research associate in geophysics in the University of Hawaii, a position he still held at the time of his death.

Dr. Jaggar's contributions to the science of volcanology have been very great. Studies of the Kilauea lava lake demonstrated its complex nature, with a shallow pool of hot fluid lava lying on a semi-solid but mobile plug. Measurements ascertained the distribution of temperature in the lake, and the composition of the liberated gases was determined. Tumescence and detumescence of the volcanic structure were demonstrated, probably resulting from changes in magmatic pressure beneath. The entire picture of volcanic activity was augmented and clarified. Perhaps most important of all, however, was the development by Jaggar and his associates of methods of aerial bombing to deflect lava flows, and the concept of huge diversion barriers to protect cities or harbours from inundation by lava. Jaggar never lost sight of the fact that the real purpose of science is to serve mankind.

Gordon A. Macdonald

We regret to announce the following deaths:

Sir David Anderson, president during 1943–44 of the Institution of Civil Engineers, on March 27, aged seventy-two.

Dr. F. W. Edridge-Green, C.B.E., for many years special examiner and adviser to the Ministry of Transport on vision and colour vision, on April 17, aged eighty-nine.

Dr. G. F. Herbert Smith, C.B.E., formerly of the British Museum (Natural History), and honorary secretary since 1921 of the Society for the Promotion of Nature Reserves, on April 20, aged eighty.

# NEWS and VIEWS

## Royal Society: Foreign Members

The following have been elected foreign members of the Royal Society: Louis Victor Pierre Raymond, Prince de Broglie (Paris), distinguished for his contributions to quantum theory; Marie Jules Constant Robert Courrier (Paris), distinguished for his contributions to endocrinology; Hermann Joseph Muller (Bloomington, Indiana), distinguished for his contributions to the chromosome theory of heredity; Wolfgang Pauli (Zurich), distinguished for his contributions to theoretical physics, in particular the formulation of the exclusion principle.

## Lister Institute of Preventive Medicine: Appointments

Prof. W. T. J. Morgan has been appointed deputy director of the Lister Institute of Preventive Medicine; Prof. Morgan is already on the staff of the Institute and is professor of biochemistry in the University of London.

Dr. B. A. D. Stocker has been appointed head of the newly created Guinness Unit for Microbiology at the Lister Institute. The establishment of this Unit, for the study of general microbiology, was made possible through the generosity of Arthur Guinness, Ltd. After a war career in the medical branch of the R.A.F.V.R., with which he served mostly in India and Burma, Dr. Stocker was successively demonstrator, lecturer and senior lecturer in the Department of Bacteriology and Immunology in the London School of Hygiene and Tropical Medicine. His research work has been directed mainly to bacterial genetics, particularly mutation-rates of flagellar antigens in *Salmonella typhi-murium*; and, during the tenure of a Commonwealth Fund Fellowship in the United States, with type transformation in *Pneumococcus* and with the transduction of genetic characters by bacteriophages in which he applied the discoveries of Zinder and Lederberg to the transduction of flagellar characters in *Salmonella*. Dr. Stocker is thirty-five.

## Contributions of Science to Peace

In his Alexander Wood Memorial Lecture for 1953, "Contributions of Science to Peace", delivered at Friends House, London, on February 18 (pp. 28; from the Fellowship of Reconciliation, 38 Gordon Square, London, W.C.1; 1*s*. 6*d*.), Prof. C. A. Coulson rejects equally the view that science alone can lead us into the world of peace or that science should be abandoned. Science, he said, will always be with us, and we can ignore neither the dangers nor the benefits it offers. There are ways in which science, by providing a better understanding of ourselves, can assist those who seek for peace. Analysis of statistical data presented by Quincy Wright in 1942 suggested that wars, of all sorts and sizes, differ qualitatively as well as quantitatively from personal quarrels and that there is no basis for the belief that the world learns by experience that war is foolish, or fruitless, or an anachronism out of which we are continually growing. It also suggests that the problems of peace are not just technological, but composite both of technology and morals. Directing attention to the way in which mankind lives continually on the brink of famine, Prof. Coulson concluded that only an enlightened scientific policy can deal constructively with situations of under-nourishment such as confront us, for example, in Persia or in the British Colonial Empire. Science, moreover, is required to improve world supplies of energy as well as of food, and Prof. Coulson referred particularly to the value which nuclear power might hold for the Middle East or India if developed there, as well as to the possibility of utilizing wind-power, the tides or solar energy. Science, properly directed and shared, he said, can help to build the defences of peace and to safeguard the freedom and spirit of men. In one sense the responsibility of the man of science does not differ essentially from that of anyone else: scientific workers are not necessarily wiser than their comrades in the use of science. Science alone is not enough; but Prof. Coulson, while welcoming the increasing concern of scientific workers with the social implications of science, did not advocate the adoption of some sort of Hippocratic oath for scientists. He suggested that what is needed is a new dedicated type of scientific worker who, recognizing the wholeness of life and the place of science in that wholeness, will not be deterred by danger or difficulty from seeking to further the contribution which science can render in shaping a new world.

## British Agricultural History Society: Inaugural Conference in Reading

The inaugural conference of the British Agricultural History Society was held at the University of Reading on April 13 and was attended by more than a hundred people representing a very wide variety of interests and professions from all over the British Isles. Sir James Scott Watson addressed the conference on "The Scope of Agricultural History", and Sir Frank Stenton spoke on "The Manor in English History". Later in the day, the conference had the opportunity of visiting the Museum of English Rural Life, University of Reading. The officers of the Society are as follows: *President*, Sir James Scott Watson (chief scientific adviser to the Ministry of Agriculture); *Treasurer*, Prof. E. Thomas (professor of agricultural economics, University of Reading); *Executive Committee*, Mr. Alexander Hay (*chairman*) (general secretary of the Association of Agriculture), Mr. Frank Atkinson (director of the Halifax Museums), Mr. John Cripps (editor of *The Countryman*), Mr. R. N. Dixey (director, Institute of Agrarian Affairs, Oxford), Mr. G. E. Fussell (author), Captain E. N. Griffith (president of the Agricultural Engineers' Association), Mr. Stuart Maxwell (National Museum of Antiquities, Edinburgh), Mr. W. E. Minchinton (lecturer in economic history, University College, Swansea), Mr. G. Ordish (Plant Protection, Ltd.), Mr. F. G. Payne (Welsh Folk Museum), Mrs. Joan Thirsk (senior research fellow in agrarian history, University College, Leicester) and Mr. R. Trow-Smith (*Farmer and Stockbreeder*). The main object of the Society, as outlined in the constitution, is to promote the study of the history of agriculture and rural economy, though it is not intended that the interests of the Society should be solely confined to the history of the British countryside. It is hoped that, by publishing a journal and holding occasional conferences, the Society will be able to bring together all those working on, or merely interested in, any aspect of rural history. Membership is open to all, the annual subscription being one guinea. Membership forms and copies of the constitution will be available shortly. All inquiries should be sent to the secretary of the Society, Mr. J. W. Y. Higgs, Museum of English Rural Life, 7 Shinfield Road, Reading.

## *Science Abstracts* on Index Cards

FROM time to time the Editor of *Science Abstracts* is asked whether an edition printed on index cards can be produced; the reply has hitherto been that the high cost of production and the limited circulation of such an edition would make the subscription-rate prohibitively high—in the neighbourhood of £40 per year for Section B (Electrical Engineering) alone. As an alternative, an edition printed on one side only was made available for anyone wanting to compile a card index of abstracts. However, a recent survey has shown that the labour of cutting and mounting single-sided issues may, in fact, raise the overall cost to a figure comparable with that of a card edition, which would, if so, be preferable for other reasons. Naturally, no precise estimate of the subscription for a card edition can be made until the probable extent of the circulation is known. To enable such an estimate to be made, the Editor of *Science Abstracts*, Institution of Electrical Engineers, Savoy Place, London, W.C.2, would be glad to hear from those willing to subscribe up to £40 per year for *Science Abstracts*, Section B, printed on index cards, 3 in. × 5 in. A similar card issue of Section A (Physics) could also be contemplated if sufficient demand was known to exist.

## Southern Regional Council for Further Education

THE fifth annual report of the Southern Regional Council for Further Education shows that, besides its regional academic board, many industrial and advisory committees have been set up since the Council was established in 1947. Most of the work of the advisory committee is concerned with trying to reconcile the requirements of industry, the requirements of students and the economic provision of further education facilities. Among the Council's activities during 1952 have been the sponsoring of courses in teaching methods which have been arranged for technical and commercial teachers. A number of conferences have also been arranged to make recommendations on metallurgical education facilities required in the region, and to discuss facilities for training agricultural craftsmen and young men in the heating and ventilating engineering industry. The Council has also published papers on the future development of higher technological education; the education and training of technologists in engineering, building, physics, chemistry and agriculture; recruitment of staff for technical colleges; instruction of rural craft workers; courses for building craftsmen; part-time instruction for agriculturists, horticulturists and domestic producers; agricultural education; and education for industrial citizenship.

## Extra-mural Function of Universities

IN an address to the Liverpool Branch of the Association of University Teachers, Mr. Thomas Kelly, the director of extra-mural studies in the University of Liverpool, indicated that the extra-mural task of a university is to make the maximum impact on the region within which it stands. The means will vary—classes; lecture courses, long and short; single lectures, recitals; exhibitions—all will have their place. In the vocational field, the university should limit its extra-mural provision to work which cannot easily be provided by other agencies; in the non-vocational field, it should seek to make provision for all groups able to profit by its services. Standards will look after themselves if the right tutors are appointed. This is the crux of all extra-mural work, and all tutors and lecturers need to be people of special qualifications. Because of this, the extra-mural resources of a university are necessarily limited, and the major task of an extra-mural department is the organization of these scarce resources in the most effective manner. A secondary task is that of studying the history, theory and techniques of adult education itself, and providing facilities for the training of tutors (*Univ. Rev.*, **25**, No. 2; February 1953).

## International Congress on Electroacoustics

AN International Congress on Electroacoustics will be held in the Netherlands during June 16–24 under the auspices of the International Commission on Acoustics of the International Union of Pure and Applied Physics. The Congress will open in the Hague on June 16 and on the following day will move to Delft, where most of the technical sessions will be held, but there will also be technical sessions (and excursions) in Hilversum and Eindhoven. The Congress will be made up of seven sections, each with a chairman who will give a general review of recent developments in the field (so arranged that all members will be able to be present), and these reviews will then be followed by individual papers and discussions. The sections, with the chairman shown in brackets, are as follows: (1) sound recording (R. Vermeulen, Netherlands); (2) public address systems (E. Meyer, Germany); (3) acoustic measurements (L. L. Beranek, United States); (4) hearing-aids and audiometers (P. Chavasse, France); (5) electro-acoustics in ultrasonics (G. Bradfield, Great Britain); (6) electroacoustics applied to musical instruments (E. G. Richardson, Great Britain); and (7) sound insulation of light-weight structures (C. W. Kosten, Netherlands). The last-named section will be in the form of a symposium. The official languages of the Congress will be English, French and German. Summaries of the papers will be circulated in advance. Application forms for membership and further information can be obtained from P. A. de Lange, Organizing Secretary of the Electroacoustics Congress, Mijnbouwplein 11, Delft.

## Chemical Meetings in Paris during June

THE second Salon de la Chimie will be held during June 18–29 in the Parc des Expositions, Paris, in conjunction with the next session of the Rassemblement des Arts Chimiques. The Salon will be organized by the Société de Chimie Industrielle, which this year will hold its twenty-sixth international congress of industrial chemistry during June 21–27 as a part of the Salon; other chemical bodies will similarly profit by the occasion by holding meetings at the same time, among which will be the following: the second session of chemical engineering, the seventh international congress of æsthetics and cosmetology, and the second symposium on proximate and functional analysis. The Salon will be divided into five sections: laboratory work and apparatus; chemical engineering; raw materials and products; organization, documentation, hygiene, etc.; and plastics. Further information of all these events can be obtained from the Secretary of the Société de Chimie Industrielle, 28 rue Saint-Dominique, Paris 7e.

## Commonwealth Fund Fellowships for Study in the United States

THE Commonwealth Fund has awarded fellowships, tenable in American universities for one year beginning next September, to the following British graduates, among others: W. G. Chaloner, University of Reading (palæobotany); R. I. Gillespie, University College, London (chemistry); H. L. Kornberg, University of Sheffield (biochemistry); D. D. Mears, King's College, London (engineering); P. G. Moore, University College, London (statistics); E. A. Power, University College, London (physics); G. C. Shephard, University of Birmingham (mathematics); R. J. Tayler, Clare College, Cambridge (astrophysics); D. G. Verney, University of Liverpool (sociology); and J. M. Williams, St. John's College, Oxford (chemistry). In addition, Dominion Civil Service Fellowships have been awarded to H. P. A. De Boom, South Africa (veterinary science), J. J. Kitshoff, South Africa (economics) and M. J. Moriarty, New Zealand (agricultural economics); and Colonial Civil Service Fellowships to F. A. Loyd, Kenya (conservation) and C. S. Ramage, Hong Kong (meteorology).

## "Protection from the Effects of Radiation"

COMMANDER P. L. CHANDLER, writing from 50 Montgomery Road, Sheffield, 7, says: "In *Nature* of February 28, p. 378, certain remarks are attributed to me, the nature of which I wish to disclaim. The policy of protection of personnel in the Naval Ordnance Inspection Department is not determined by the 'delivery of the goods'. The regulations laid down by their Lords Commissioners to the Admiralty are strict and conform to recommendations as accepted throughout the radiological world. These regulations as laid down are fully complied with in the Naval Ordnance Inspecting Department and those in force are such that the very minimum dose is obtained by personnel employed in the Radiological Department, and this is confirmed by daily readings with ionization chambers and regular readings by N.P.L. film batches".

## Announcements

SIR ROBERT ROBINSON, Waynflete professor of chemistry in the University of Oxford, has been awarded the Priestley Medal of the American Chemical Society, the Society's highest award.

SIR JOHN LENNARD-JONES has been awarded the Hopkins Prize of the Cambridge Philosophical Society for his work on the mathematical theory of molecular structure. The Prize is awarded every three years to a member of the University of Cambridge adjudged to have published the best original work in connexion with mathematico-physical or mathematico-experimental science in the relevant three-year period. The present award is intended to refer to the period 1945–48. The first recipient was Sir G. G. Stokes in 1867.

THE COUNCIL of the Institute of Metals has elected Sir Arthur Smout (past-president) a Fellow, in recognition of his long and distinguished services to the Institute; the number of Fellows is limited to twelve. Sir Arthur Smout was chairman during 1934–42 of what is now known as Imperial Chemical Industries, Ltd., Metals Division.

MR. DAVID P. RAMSOME, a descendant of Robert Ramsome, the well-known agricultural engineer, and managing director of E. H. Bentall and Co., Ltd., has been elected president for 1953–54 of the Institution of British Agricultural Engineers.

DR. W. IDRIS JONES, director-general of research to the National Coal Board, has been elected president of the Institute of Fuel for the session 1953–54; he will succeed the retiring president, Dr. G. E. Foxwell, in October.

THE following appointments have been made in the University of London: Dr. L. F. Lamerton to the readership in physics applied to medicine, tenable at the Institute of Cancer Research, Royal Cancer Hospital; Dr. Miles Weatherall to the University readership in pharmacology, tenable at the London Hospital Medical College.

DR. S. F. MASON, formerly of Wadham College, Oxford, has been appointed a Research Fellow of the Department of Medical Chemistry of the Australian National University; he took up his duties on April 1 in the Department's laboratories, which are at present at 183 Euston Road, London, N.W.1.

THE fifth annual symposium on phytopharmacy, organized by a number of Belgian and Dutch organizations and companies interested in this field, will be held in the Institute of Agronomy, 233 Coupure, Ghent, on May 5. The majority of the papers will be in Dutch or French. Further information can be obtained from the secretary, R. H. Kips, Rijkslandbouwhogeschool, Coupure 233, Ghent.

THE Scientific and Technical Group of the Royal Photographic Society is organizing a conference on "Photographic Science and Technique", to be held in the Arthur Worthington Hall, University of Manchester, on May 16. A number of short papers will be read, with subsequent discussion, on some problems and uses of photography in scientific, industrial and medical work. The conference will be open to all; those who hope to attend should inform the Group Honorary Secretary (D. H. O. John, 62 Chelmsford Road, Shenfield, Brentwood, Essex), from whom further information can be obtained.

THE Society for Endocrinology is arranging a symposium on "The Determination of Adrenal Cortical Steroids and their Metabolites", to be held at the Medical Society of London, Chandos Street, W.1, on May 21 at 9.30 a.m. Non-members of the Society wishing to attend should write to Prof. N. F. Maclagan, Westminster Medical School, London, S.W.1. The Society also announces that a lecture on "The Prostatic Glands as Targets for Steroids" will be given by Dr. Charles Huggins (Ben May Laboratory for Cancer Research, University of Chicago) at the Royal Society of Medicine, Wimpole Street, London, W.1, on June 23 at 5.30 p.m. Admission is free and without ticket.

A COURSE on "Geography and Food Resources", to be held at Westham House Adult Residential College, Barford, near Warwick, during May 22–26, has been arranged by the Association of Agriculture with the co-operation of Captain F. Owen, principal of Westham House. After an opening talk on factors limiting world food production, other lectures will deal with land use and agricultural geography of Great Britain, the Dominions, Europe and the tropics. The fee for the course, which is residential, is £3 12*s.* 6*d.* Applications should be addressed to the General Secretary, Association of Agriculture, 238 Abbey House, 2 Victoria Street, London, S.W.1, from whom further details can be obtained.

ERRATUM. In the account of the Bose Institute, Calcutta, in *Nature* of March 14, p. 468, the director was referred to as Dr. R. C. Mazumdar. This should read Dr. D. M. Bose.

# ELASTICITY IN LIQUIDS

A SYMPOSIUM on elasticity in liquids, arranged under the auspices of the British Society of Rheology, was held on March 27 in the Department of Science of the Durham Colleges in the University of Durham. Mr. J. E. Caffyn organized the details of the meeting.

Prof. J. E. P. Wagstaff welcomed the members to Durham, and the morning session then opened with Prof. G. S. Rushbrooke in the chair. Dr. R. Roscoe first read a paper on elastic relaxation and flow in suspensions, in which he referred to the early experiments of Schwedoff on relaxing sols. The method involved placing a gelatine solution in a co-axial cylinder viscometer, suddenly applying a shear by twisting the torsion head which supported the inner cylinder and observing the stress on the system as it relaxed slowly. Schwedoff considered that the stress fell off exponentially; but later workers do not confirm this. Dr. Roscoe has found, however, by repeating their experiments, that departure from the exponential decay is a feature of viscometers with a wide gap between the cylinders. By writing down the flow equations for such an apparatus, he is able to deduce a form of decay for the stress which agrees with experiment.

In the second part of his paper, Dr. Roscoe discussed the relation between rate of shear and shear stress, under steady conditions. Equations of flow have been developed by a generalization of Maxwell's method, which reduce to Bingham's equation in the case of steady flow. The cause of observed departures from Bingham's equation was discussed.

Dr. S. Thornton, speaking on the rheological behaviour of some dispersions of solid particles in liquid media, considered the effect of particle concentration on the relative viscosity of suspensions of rigid non-flocculating particles, and he developed a general expression applicable not only to spherical particles, in agreement with Einstein's well-known equation, but also to non-spherical particles of a limited type over a limited range of concentration. After a brief review of the experimental work on this subject, he stressed the need for checking the absence of flocculation of the particles and for ensuring the validity of any corrections applied. He explained briefly the technique for measuring the absolute viscosity of thixotropic materials which do not exhibit elastic behaviour, and gave results for some special cases.

Dr. E. G. Richardson described some experiments now in progress on the relationship between shear and bulk viscosity. Stokes first deduced a formula for the absorption of plane waves in a gas, the theory making the coefficient ($\alpha$) proportional to the square of the frequency ($f$) and the kinematic viscosity ($\nu$). In many liquids $\alpha/f^2$ is constant (with frequency) but has a value much greater than that of Stokes's formula, if the shear viscosity is substituted for $\nu$. It has been suggested that the bulk, or dilatational viscosity, should be included in $\nu$ when the propagation of ultrasonic waves is concerned. One experiment, suggested by Eckart, for the determination of bulk viscosity is based on the mensuration of the acoustic streams in the neighbourhood of a vibrating source, and a study of this is being made using hot wires to measure the streaming velocities in various fluids at frequencies from 1 c./s. to 1 Mc./s. Another method is to study the absorption of ultrasonics in capillary tubes, wherein plane waves are propagated in the centre of the tube and shear waves in the acoustic boundary-layer near the walls. Some initial results in both experiments were quoted.

In the afternoon session, with Dr. J. G. Oldroyd in the chair, J. E. Caffyn and R. M. Underwood described a new method for delineating velocity profiles in visco-elastic liquids. This involves the delineation of the motion of isolated oil drops, suspended in the liquid under test flowing along a tube 1 cm. in diameter, by double-flash photography from two perpendicular directions. From the double exposure of the oil drop on the photograph, the velocity at different radial distances from the axis of the tube can be estimated (and incidentally any deviation from axial flow detected), and hence the velocity profile at the site of the photographs to be constructed. Examples in water (for calibration purposes) and in an ammonium oleate sol were shown. In the visco-elastic fluid the velocity distribution, in accordance with the theories of Oldroyd and of Reiner and Rivlin, is still parabolic.

The final paper, by Dr. A. S. Lodge, considered some theories of the Weissenberg effect, and dealt with the distribution of transverse pressure in a rotating cone-and-plate viscometer, when the interspace is filled with a visco-elastic liquid in which components of stress perpendicular to the direction of shear are set up. The paper was theoretical and dealt with the fluid in stationary laminar incompressible flow, for which the general stress determinant was constructed. The difference between stress components (zero in a Newtonian fluid) give rise to the Weissenberg effect, as Dr. Lodge showed. Having calculated these differences for various radial distances in the cone-and-plate apparatus, he can compare the theory with the measurements of Roberts, who erected a series of manometers from the centre to the rim of the cone above the rotating plate and so was able to measure the transverse (vertical) stress distribution in a number of visco-elastic liquids. In the discussion on this paper, Dr. K. Weissenberg pointed out that Roberts's experimental results agree with his own calculation of the stress distribution.

---

# MATHEMATICAL ASSOCIATION

## ANNUAL GENERAL MEETING IN SHEFFIELD

THE annual general meeting of the Mathematical Association was held in the University of Sheffield during April 8–11. At a reception given by the University on April 8, Dr. J. M. Whittaker, the vice-chancellor, welcomed the members, among whom was his father, Sir Edmund Whittaker, honorary member of the Association and president in 1919.

On April 9, following the business meeting, the president, Mr. K. S. Snell (Harrow School), gave his address, his subject being "School Mathematics To-day and To-morrow". Mr. Snell began with a speculation on the probable content of the school curriculum fifty years hence, suggesting that many topics now regarded as well outside the school range would by then have become commonplaces of the grammar-school curriculum. He then went on to examine present-day tendencies, to discuss which items might be emphasized and which might be allowed to fall into oblivion. One way in which much time might be set free for the development of the school course in mathematics would be to reform the British weights and measures—those tables which demand for their acquisition a great deal of time and effort—and Mr. Snell made a strong plea for the adoption of a suitable metric system in Britain.

Prof. A. G. Quarrell (Department of Metallurgy, University of Sheffield) then gave a paper on "Metallurgy—Craft and Science", describing the combination of craftsmanship and scientific investigation required in the production of high-quality steel; by the courtesy of Firth Brown, Ltd., a colour film showing modern methods of steel production was shown to the audience.

On April 10 the proceedings opened with a discussion on "Infinity", in which Prof. A. G. Walker (University of Liverpool) elucidated the concept of infinite numbers, and Dr. C. Hamill (University of Sheffield) spoke on the meaning and place of infinity in geometry. In the succeeding discussion some members thought that a simple account of these topics might be presented to a sixth form; but others urged that this was a subject which should be reserved exclusively for the university course.

The next paper, "The Mathematics Division, N.P.L.: its Work and Equipment", was to have been given by Dr. E. T. Goodwin, the superintendent of the Mathematics Division in the National Physical Laboratory; in his absence, through illness, Dr. L. Fox, the deputy superintendent, spoke on this topic, describing the range of machines, from the hand-operated adding and multiplying machines up to the A.C.E. electronic computer. Dr. Fox also dealt with the part played by the mathematician in analysing and systematizing the problems submitted to the Division before handing them over to the computing machines.

In the afternoon of the same day, a long and lively discussion was held on a subject which has greatly concerned the Association in recent years: "From Primary School to Secondary School". The opening speakers were Mr. L. B. Birch (deputy director, Sheffield University Institute of Education), Mrs. E. M. Williams (principal, Whitelands Training College) and Mr. M. W. Brown (headmaster, Charlton Secondary School). It was urged that free activity is the only method which will enable the average child to understand the mathematical processes of the primary-school range; but some secondary-school teachers feared that the freedom of activity might encourage the child to avoid hard work and might lead to a state in which pupils arriving at the secondary school would not have the firm grasp of fundamentals required for the school programme. In return, it was argued that understanding must precede technical skill and that manipulatory techniques are much more rapidly acquired if genuine understanding and appreciation of mathematical principles have been fostered in the primary school. But no easy solution to the practical problem of applying modern ideas to classes of forty or fifty children was put forward. In the evening, Dr. S. Vajda (Admiralty Research Laboratory) gave a paper on the "Theory of Games", a subject which, initiated mainly by John von Neumann in the 1920's, has proved to have wide applications to economics and also to the highly important war-time study of operational research.

The final paper, on April 11, was by Mr. J. F. Hinsley (chief radiologist and physicist, Edgar Allen and Co., Ltd.), who chose as his subject "From Examination Question to Industrial Problem". Here Mr. Hinsley showed that certain familiar examination questions concerning the motion of a particle, usually thought of as possessing only academic interest, are in fact of very considerable practical value in the design and testing of cement-making machines.

The new president of the Association is Prof. T. A. A. Broadbent, of the Royal Naval College, Greenwich.

# SCOTTISH BRANCH OF THE SCIENCE MASTERS' ASSOCIATION

## ANNUAL MEETING IN EDINBURGH

THE Scottish Branch of the Science Masters' Association held its annual meeting during April 7–10 at the Heriot-Watt College, Edinburgh, under the presidency of Dr. H. G. Nisbet, principal of the College. In his address, on "Some Applications of Physics in the Fuel and Oil Industry", Dr. Nisbet described the various methods of cleaning and grading coal, using such principles as flotation and electrostatic attraction. The difficulty of efficient cleaning becomes greater as the size of the coal particles decreases, and he attributed much of the dirtiness of our coal to-day to the increased proportion of very small particles in coal won by modern mechanized techniques. Turning to liquid fuels, Dr. Nisbet explained how 'knocking' or 'pinking' is due to abnormal rates of flame propagation, which can be corrected by the use of suitable catalysts such as tetra-ethyl lead. He next dealt with the problem of making efficient use of the fuel resources of Great Britain, and ended with a plea for more chemical engineers who, by increasing this efficiency, could help the country to maintain its place as a leading industrial nation.

Mr. R. M. Sillito, of the University of Edinburgh, gave an excellent lecture-demonstration on "Sound in Schools", with special reference to the new Scottish Leaving Certificate syllabus. He ended by asking that school pupils should be trained in the habit of precise quantitative thinking, which, he maintained, is far more valuable as a basis for university work than mere factual knowledge.

Two consecutive lecture-demonstrations on "A Theoretical and Practical Approach to the Teaching in the M.K.S. System of Electrical Units" were then given by Mr. F. A. Meier, of the University of London Institute of Education. This again had special significance in view of the new Leaving Certificate syllabus, both as regards the M.K.S. system itself and also as regards the approach via electromagnetic induction instead of magnetometry. His demonstrations of home-made apparatus, much of it being designed on original principles, were most impressive. Mr. Meier stressed the point that the new system and approach are far easier than the old, provided we can rid ourselves of our preconceived notions.

In a lecture on "School Astronomy" given at the City Observatory, the director, Mr. N. G. Matthew, asked science masters to try to make time for some astronomy in an admittedly crowded syllabus, and outlined methods by which the subject might be presented. He concluded by explaining a way in which senior pupils in Scotland can join in research by enrolling as members of the team of observers who are reporting on appearances of the aurora borealis. Mr. W. Fulton gave a demonstration of modern methods of sound reproduction, including tape-recorders. He ended by demonstrating a sound-film with a double sound-track—the original optical track, and a magnetic sound-track added later by a special process and giving entirely different sound. This very recent development may have great possibilities for such purposes as the addition of a translated commentary to foreign sound-films.

Prof. G. F. Marrian, professor of chemistry in relation to medicine, University of Edinburgh, gave a lecture on "Careers in Biochemistry". He outlined the history of biochemistry from a borderline-subject to one standing in its own right, and then went on to consider the problem of training, in which he expressed the view that an honours degree in chemistry or in biochemistry is of approximately equal suitability as a start ; but, in addition, several years of research leading to a Ph.D. are practically essential. Prof. Marrian mentioned the openings for biochemists in universities, research units, hospitals and industry, and made a special plea for more biochemists to take up agricultural research in order to help improve the food situation in Great Britain. Finally, he said that the demand for biochemists is limited, the post-war shortage having been filled up ; but for a few students of high standard there is an opportunity of working in a field of science which is developing very rapidly. In a lecture on "Some Recent Developments in Organic Chemistry", Dr. Neil Campbell, of the University of Edinburgh, first dealt with modern sources of organic materials and showed how petroleum is replacing coal-tar as the main source. Then he went on to discuss modern trends in theory and practice, including the theory of orbitals and the use of fluorescence and chromatography.

Other features of the meeting included the annual business meeting, visits to places of interest, exhibitions by members, publishers and manufacturers of scientific apparatus, and a glass-blowing demonstration by Mr. D. Macdonald, chief glass-blower in the Heriot-Watt College. A discussion was also held on "Recent Publications of the Scottish Education Department", which resolved itself largely into an expression of apprehension that the new syllabus in Circular 249 is too long to be covered in the time available at most schools, although it was conceded that the syllabus has great merits in other ways and should be given a fair trial.

# ROTHAMSTED EXPERIMENTAL STATION

## REPORT FOR 1951

THE report of the Rothamsted Experimental Station for 1951 shows that the station has again been the venue of a number of important conferences, that overseas visitors have been even more numerous than in previous years, and that the services of members of the Rothamsted staff continue to be sought by many different countries.

Field work with fertilizers, which has a primary place in the Rothamsted tradition, some of it in conjunction with other centres, is giving indications that some of the newer fertilizers, particularly silicophosphate, are likely to give good results. Nitrophosphates (formed by the action of nitric acid on rock phosphate and subsequent treatment with ammonia) consist essentially of ammonium nitrate and dicalcium phosphate, but there are some chemical and physical differences arising from different ways of production which appear to make some of them a little more effective than others. Two kinds examined at Rothamsted did not on the whole give quite the same yields as the same amounts of nitrogen and phosphate in sulphate of ammonia and superphosphate, but the results suggest that improvements in physical conditions can give a very useful nitrophosphate. Work with the older fertilizers is still giving positive suggestions, and some field results indicate that superphosphate may in some circumstances be used in much smaller dressings than have usually been advocated.

Other work in the Chemistry Department is concerned with the placement of fertilizers and with nutrition problems in forest nurseries.

Consideration of the relation of soils to ions in solution has been based by many workers on Gouy's double-layer theory, and the Physics Department has done very useful work by a critical examination that supports the justification for this use of the Gouy theory. This study is advancing our understanding of the behaviour of the aluminium ion, of the hydrogen-ion concentration in the soil-solution system and of the flocculating and deflocculating effects of salts. The Department is continuing its work on soil cultivation and its investigations in agricultural meteorology.

The study of clay minerals continues in the Pedology Department ; the work has included examination of a number of African soils, and a study of the absorption of organic compounds by clays. Further results of the study of gleying in soils offer some interesting suggestions. The reducing power of fermenting plant material (dealt with in the 1950 report) is much in excess of the iron actually reduced in the soil, and the rate of solution of the ferric oxide seems to be the limiting factor. Mottling with iron rust, so common in many gley layers, is only present in old root channels : elsewhere there is only grey material that is characteristic of the reducing action in gleying.

In the Microbiology Department the important work on nitrification is being continued, and the study of antibiotics secreted by actinomyces is producing some interesting results which may well lead to economic applications. Some of the clay and humic matter acts as an absorbent of the antibiotic, and some organic matter may act as a nutrient to the actinomyces and as an absorbent of its antibiotic. Another interesting piece of work shows that some reductions in soils are not unnecessarily anaerobic, for sulphates can be reduced with the production of hydrogen sulphide by aerobic organisms.

Work in the Botany Department on the uptake of nutrients by roots has been going on for some time, and some of it has recently been published. The uptake of an element seems to depend on the carbohydrate content of the root and the concentration of the particular element concerned, but is not affected by the concentration of other elements in the root cell. These studies are now involving the use of

---

* Rothamsted Experimental Station. Report for 1951. Pp. 212. (Harpenden: Rothamsted Experimental Station, 1952.) 7s. 6d.

whole plants, and not merely excised roots, and should throw valuable light on an important and much-discussed subject. Further work on the spraying of leaves with nutrient solutions shows appreciable increase in growth following this treatment and sometimes, but not always, increases the percentage of nitrogen and phosphorus in the dry matter. Some work is being done on the possible replacement of potassium by sodium, and it has been shown, arising out of this work, that the effect of potassium deficiency on carbohydrate production does not account for the decrease in plant growth, since leaves sprayed with sucrose absorb the sugar without any increase in growth.

The Plant Pathology Department has continued its study of viruses and the influence of ultra-violet radiation on their effects. There is much other work on viruses and considerable mycological work, including some important observations on the spreading of spores.

The Biochemistry Department is carrying on the work on nucleoproteins from both normal and infected leaves. Rothamsted is giving up its responsibility in the technological production of leaf protein, which will now be carried on independently by the Grassland Research Station. The oxidation of manganese in certain plants is found to take place by the action of hydrogen peroxide forming in the plant under the influence of a peroxidase. A study of the parts of fungal mycelia that accumulate in soils in a very resistant form will contribute to our knowledge of the structure and properties of soil organic matter.

Different strains of eelworms that attack various crops and weeds are still being investigated in the Nematology Department, and immune varieties of crops are being sought.

Other work includes the study of insect populations, the feeding habits of bees, the effects of insecticides and the influence of insecticides on soil microflora. The Statistics Department continues to design experiments not only for Rothamsted but also for many other centres.

Some of the work (virus diseases in sugar beet, manganese oxidation in plants, and the movement of insects) are the subject of special reviews in this report, and the publication also contains, as usual, a brief report of the Soil Survey of England and Wales and a list of Rothamsted publications.

---

## CHECK-LIST OF THE BIRDS OF GREAT BRITAIN AND IRELAND

THE scientific names of British birds have suffered from many changes, which has caused much inconvenience and some confusion. The British Ornithologists' Union has on three separate occasions, between 1883 and 1923, published lists of the birds on the British list with what were considered their correct scientific names. Unfortunately, however, the various authors responsible for these lists did not always pay strict attention to the International Rules of Nomenclature. Six years ago the Union decided that it was time a fresh list was prepared, and a committee was appointed; the new "Check-list of the Birds of Great Britain and Ireland" is the result of its labours*.

The committee had three tasks before it: to decide on the correct scientific names; to investigate the claims of certain rare wanderers to be admitted to the British list; and to examine the twenty-nine races of British birds described since the publication of the previous list. Of these new races, twenty-four were described by one individual, and out of the total the committee has only been able to recognized six.

Most of the changes in scientific nomenclature are already in use, but the committee has made two innovations regarding the use of English names. In the first place, the English name is restricted to the species, and only in a few exceptional cases is one given for a race. The second change is that the name is given by which American birds (either regular visitors or rare wanderers to Britain) are known in Canada or the United States, as well as the recognized British name. For example, the peregrine falcon is called the duck-hawk on the western side of the Atlantic, and the grey phalarope is known as the red phalarope. The general distribution of both species and races is briefly given, and should be very useful to curators and others.

The committee is to be congratulated in bringing its labours to a satisfactory conclusion, and a word of praise is due to the secretary, who, together with the chairman, are the only original members of the committee. The president of the Union, Sir Landsborough Thomson, has written an admirable introduction, which users of the check-list should read carefully.

* Check-List of the Birds of Great Britain and Ireland. (Published by the British Ornithologists' Union.) Prepared by the List Sub-Committee. Pp. xii+106. (London: H. F. and G. Witherby, Ltd., 1952.) 7s. 6d.

## NATURE OF 'FIELD RESISTANCE' OF THE POTATO TO *PHYTOPHTHORA INFESTANS* DE BARY

By K. O. MÜLLER

**National Institute of Agricultural Botany, Cambridge**

AND

J. C. HAIGH

**Scottish Society for Research in Plant Breeding, Edinburgh**

ALL attempts have hitherto failed to find 'true resistance', that is, resistance by virtue of suprasensitivity (= hypersensitivity), to *Phytophthora infestans* in the European cultivated potato, and there is good reason for thinking that this form of resistance will not be found in any old-established cultivated variety, not even in South America from whence the potato was brought to Europe four hundred years ago. Suprasensitivity, however, to various biological strains of the parasite has been obtained in commercial varieties in recent years by German, British and American breeders, but only by crossing cultivated forms with *Solanum demissum* or other wild *Solanum* species which may possess this type of resistance. Nevertheless, it has been known for a hundred years that considerable variation can be observed among old-established varieties in the reaction to blight under field conditions. This variation of what may be called 'field resistance' is found in the time of the first appearance of the disease and in the speed with which it increases to epidemic proportions within the plot; further, there is correlation between the rhythm of development of the host and the epidemic behaviour of the parasite—the later the variety would mature under disease-free conditions, the later, as a rule, the disease becomes epidemic.

This obvious relation between rhythm of development of the host and epidemic behaviour of the parasite, together with the fact that, under European conditions, blight generally reaches epidemic proportions not earlier than flowering time (therefore 'late' blight) has led many authors to the conclusion that blight is an "age-disease"; they have assumed that a "lowering of efficiency of immune reactions" takes place with increasing age and that this ontogenic change occurs much more quickly in early varieties than in late ones. There is, however, no conclusive experimental proof of such a change; moreover, under different climatic conditions—for example, in Turkey near the Black Sea or in many parts of Chile and in South Africa—blight often appears at epidemic proportions much earlier in the season; long before the plants reach the flowering stage.

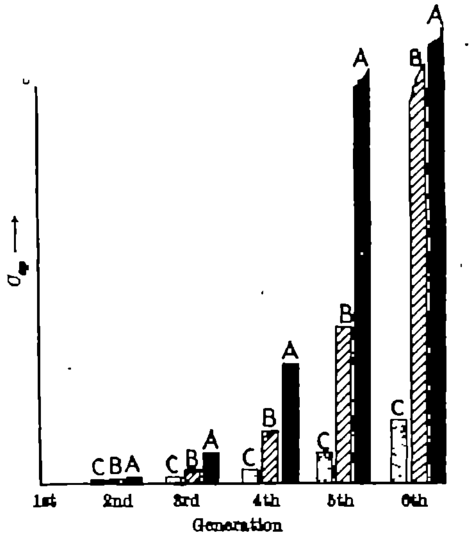
A new attempt to explain the observed facts is based on the following working hypothesis. Potato blight belongs to the group of airborne plant diseases. Under the climatic conditions of the major potato-growing areas of Europe, the parasite has to start at the beginning of each new season from comparatively small foci of infection, and it takes a relatively long time for the disease to reach epidemic proportions (numerous observations of one of us (K. O. M.) indicate that at least five generations of the parasite are necessary to infect a larger plot from a few primary foci of infection). Supposing that the spread of sporangia within the plot is homogeneous and their increase according to geometrical progression, the infestation of a plot is assumed to proceed according to the following formula:

$$C_{ep} = (c.P_I)^n,$$

where $C_{ep}$ is degree of infestation, $P_I$ is "probability of becoming infected per unit area of leaf", $c$ is intensity of fructification per single leaf spot, and $n$ is number of generations of the parasite since the initial infection.

This formula cannot reflect the actual situation within a field-plot; it can only illustrate the principle on which the working hypothesis is based. For example, it assumes that there is only one primary infection and that subsequent spread is internal; the assumption is justified on the grounds of mathematical simplicity by the heuristic character of the equation. Further, all the factors on the right-hand side of the equation are affected by constantly changing environmental conditions, particularly temperature and humidity. Also, since the epidemic effects of differences of $P_I$ will be in inverse ratio to the number of spores hitting the foliage, we may expect the effect to be greater at the beginning of the blight attack than later; and for the same reason, the effect of $P_I$ values on the rate of spread of the disease will vary directly with the distance of the plants from the source of infection.

Nevertheless, assuming that $P_I$ would be the only factor in which three varieties $A$, $B$ and $C$ differ from one another, the differences being in the proportion $A : B : C = 100 : 75 : 50$, and that the density of sporangia sweeping over the plot is homogeneous, then the accompanying diagram illustrates the consequences which would follow from the working hypothesis. It indicates that considerable differences between the $C_{ep}$ values of the varieties concerned are to be expected after four generations of the parasite, and that these differences should increase with increasing age of the plant, so that variety $A$ succumbs much earlier than varieties $B$ or $C$. Conversely, since in early varieties blight usually appears earlier and increases faster to epidemic proportions, these varieties should have greater $P_I$ values than late-maturing ones.



The technique used for testing this working hypothesis will be described in detail in a subsequent paper. Briefly, it consisted of inoculating fresh pieces of leaf of the same size with a weak zoospore suspension which was sprayed on them in dishes by means of an atomizer. The pieces of leaf were examined under the binocular microscope after four or five days and were 'scored' as 'diseased' or 'not diseased'. In the experiments here described a 'common' ($A$) strain of the parasite was used.

The arrangement of the pieces in blocks, with each variety or treatment equally represented and randomized in each block, made possible a statistical analysis of the results of inoculation. The degree of infection, measured for each variety by the number of pieces of leaf attacked (per block), was expressed as a percentage of the number of pieces inoculated (per block), and these percentages were converted by the $\sin^2\theta$ transformation before being subjected to an analysis of variance. These $\sin^2\theta$ figures, referred to as the $R_I$ values, were used as a measure of the $P_I$ values of the varieties. As an example, a test with field plants may be quoted in which there were four varieties: Champion, Stormont Dawn, Home Guard and King Edward. Each variety was represented by forty-four pieces of leaf, arranged in four blocks. Counts were made five days after inoculation and gave the following total numbers of pieces infected: Home Guard, 36; Champion, 14; King Edward, 41; and Stormont Dawn, 14. When the figures which contributed to these totals were expressed as percentages for each block and the percentages converted by the $\sin^2\theta$ transformation, the analysis of variance became possible (Table 1).

Differences are significant at the 1 per cent level and show Champion and Stormont Dawn to be significantly less infected than Home Guard or King Edward.

The essential experiments were carried out with twelve varieties grown at the National Institute of

Agricultural Botany in Cambridge during 1951. Unfortunately, blight appeared at epidemic proportions rather late in the year, the first being observed only in the second half of August. The names and abbreviations, maturity and reaction to blight infection in the field of the varieties used are given in Table 2.

During the period between the end of June and the middle of September, nine series of tests including all these varieties were made on pieces of leaf by the method just described. In Table 3 the results (mean values) of the four laboratory tests carried out between August 1 and 27 are plotted against the reaction of the varieties to blight in the field.

Table 3

| Field observations | | sin² θ (mean values)<br>20·0–24·9 | 25·0–29·9 | 30·0–34·9 | 35·0–39·9 | 40·0–44·9 | 45·0–49·9 |
|---|---|---|---|---|---|---|---|
| Resistant | 1 | OH. | | | | | |
| ↑ | 2 | ST.D. | | | | | |
| | 3 | | | U.S. | K.E. | | |
| | 4 | | A.V. | | | | |
| | 5 | | | | M. | | |
| ↓ | 6 | | | | | U.EM. | |
| Susceptible | 7 | | | | B.H.G.<br>U.CH. | U.EN. | A.P. |

Table 4

| Order of maturity | | sin² θ (mean values)<br>20·0–24·9 | 25·0–29·9 | 30·0–34·9 | 35·0–39·9 | 40·0–44·9 | 45·0–49·9 |
|---|---|---|---|---|---|---|---|
| Early | *A* | | | | U.CH.<br>H.G. | U.EN. | |
| ↑ | *B* | | | | B. | U.EM. | A.P. |
| | *C* | | | | K.E.<br>M. | | |
| ↓ | *D* | OH. | A.V. | | | | |
| Late | *E* | ST.D. | | U.S. | | | |

It will be seen from the table that there is correlation between the 'probability of becoming infected per unit area of foliage' (as measured by $R_I$) and the behaviour of the varieties in the field: the later blight appears and the more slowly it increases to epidemic proportions under field conditions, the smaller are the $R_I$ values obtained in the laboratory. In Table 4 the results are plotted against the varieties arranged in order of maturity in the field, and there is again seen to be an orderly arrangement in which the chance of becoming infected increases with decreasing maturity of the variety.

Of all the varieties under trial, the latest incidence of blight in the field-plot and almost the lowest $R_I$ values in the laboratory were shown by Champion, an old-established British variety which has been known as an outstanding 'blight-resister' for a long time. The results of these tests not only confirmed its field resistance, but also showed that the late incidence of blight in this and similar varieties is by no means the result of a belated lowering of efficiency of immune reactions with increasing age. On the contrary, there are strong indications that an ageing leaf becomes less susceptible to infection. The reason why the disease appears relatively late in the season in these varieties is largely because in them the probability of becoming infected ($P_I$) is relatively low, and in years when the disease occurs only in small proportions, these varieties will often escape severe attack.

Table 1

| Variety | Block 1 | Block 2 | Block 3 | Block 4 | Totals | Mean |
|---|---|---|---|---|---|---|
| Champion | 25·3 | 47·6 | 17·6 | 42·4 | 132·9 | 33·2 |

7 = most early appearance and quick increase of the disease
1 = latest appearance and slow increase at the end of the season

Other experiments, to be described in detail in a subsequent paper, have shown that environmental conditions can affect the $P_I$ value of a plant; for example, plants raised in the greenhouse will usually show a higher degree of infection than plants grown in the field. It has also been found that there are no significant varietal differences of $R_I$ values if the spore suspension is sprayed on to the lower surfaces of the pieces of leaf, indicating, among other things, that natural infection usually takes place on the upper surface of the leaf. Evidence in support of the existence of differences in the factor $c$ in the formula $C_{sp} = (c.P_I)^n$ will also be presented. Finally, the experiments showed that the factor or factors which control the 'chance of becoming infected' are independent of the strain of *Phytophthora* which is used for the determination of $R_I$ values, indicating that such factors are different from those which confer resistance due to suprasensitivity. The potato breeder who wishes to obtain the highest possible degree of blight resistance in his breeding material should therefore combine both qualities by crossing varieties with low $P_I$ values and suitable maturity with those which possess 'true resistance' by virtue of suprasensitivity.

We wish to acknowledge the assistance received from Miss M. Kostrowicka in carrying out numerous $P_I$ tests and in observing the behaviour to blight of the field plots at the National Institute of Agricultural Botany during 1951.

# EFFECT OF NERVOUS STIMULATION ON THE ARTERIO-VENOUS OXYGEN AND CARBON DIOXIDE DIFFERENCES ACROSS THE KIDNEY

By Dr. JOSEPH H. CORT

Laboratory of Physiology, Yale University School of Medicine, New Haven, Conn.*

THE kidney usually receives about 25 per cent of the cardiac output[1] and thus probably has far more oxygen available than it can extract under ordinary metabolic conditions. This same high rate of tissue-flow greatly dilutes the carbon dioxide returning to the circulation, in relation to other tissues. Normally, therefore, the arterio-venous differences of these gases are small, and any changes produced in them experimentally are even smaller in absolute value. Indeed, attempts to increase the osmotic reabsorptive work of the kidney have produced no measurable change in oxygen utilization[2], and change in oxygen uptake seems to correlate best with blood flow[3]. Consequently, measurable changes in arterio-venous differences may be taken to indicate changes in blood flow rather than tissue oxygen consumption. The work reported here is an attempt to use gaseous differences across the kidney as a measure of the changes in renal blood-flow produced by nervous stimulation.

Fourteen adult cats were used under 'Nembutal' anæsthesia, 30 mgm./kilo administered half intraperitoneally, half intramuscularly. Arterial blood samples were drawn from the femoral artery, while renal blood was collected through a No. 5 or 6 straight cardiac catheter, passed from the internal jugular vein in the neck into the left renal vein with the aid of a fluoroscope. The left renal vein was used because it joins the vena cava at a more acute angle than the right and is longer, thus providing more mechanical security for the catheter position during the experiment. The position of the catheter was verified in each case by post-mortem examination. All blood samples were drawn under oil in heparin-moistened syringes and analysed directly. Urine flow, when measured, was obtained through an in-dwelling catheter in female cats.

Systemic blood pressure was measured with a mercury manometer attached to a carotid cannula.

The portions of the nervous system stimulated were: (*a*) the central end of the severed sciatic, (*b*) peripheral end of the cut splanchnics (exposed by a dorsal approach to the crus of the diaphragm) and (*c*) the supraorbital areas of the cerebral cortex (exposed by superior craniectomy and retraction). The peripheral points were stimulated by means of a thyratron discharge at a frequency of 150/sec.; cortical stimulation was carried out with a 10/sec. square wave of 10 m.sec. pulse-width produced by a multivibrator.

The orbital surface was chosen for cortical stimulation upon the evidence presented by Ward and McCulloch[4] that there are direct unmyelinated connexions from this area to the head ganglia of the sympathetic nervous system in the posterior hypothalamus. The supraorbital surface was just lateral to the posterior third of the olfactory nerve on the concave under-surface of the cat's brain. Renal vein catheterization was completed before craniectomy in every case, so that the effects of the rongeuring of cranial bone could be determined immediately after exposure.

The effects of stimulation on arterio-venous oxygen and carbon dioxide differences are shown in the accompanying table. Oxygen figures are expressed as an arterio-venous difference, while carbon dioxide appears as a venous-arterio difference. The direction of change was the same in every animal with every stimulation, and the figures presented are averages of the differences. The changes are compared with pre-experimental levels determined in triplicate over a half-hour period. The peripheral stimulations were applied for 5 min. continuously. In the case of the sciatic stimulation a drop of about 50 per cent was produced in both gaseous differences. After a period of 10–30 min., the original levels had either been restored or had been exceeded. This phenomenon was easily repeatable in the same preparation, if a rest period of at least 30 min. was allowed between successive stimulations. The figures show that splanchnic stimulation produced a slightly greater change than sciatic stimulation in the same direction. The time relationships of stimulation were also similar. The effects of craniectomy are listed separately: both gaseous differences were depressed slightly, and the depression tended to continue for some time after exposure. This depressed value was taken as the base-line for the subsequent stimulation, which produced a further parallel decrease in both differences of long duration. No significant recovery occurred in most cases by 45 min. after stimulation had ceased.

Urine production completely ceased with the onset of all stimulations and gradually returned during the subsequent period. The restoration of the flow of urine usually coincided with the recovery of gaseous differences. Systemic blood pressure rose sharply in response to peripheral stimulation, but fell again to its original base-line value usually by 30 sec. after stimulation had been initiated. In response to cortical stimulation the rise (20–40 mm. mercury) of systemic blood pressure was slower (1–2 min.) and the decline showed a similar time course.

Supraorbital stimulation, in contradistinction to all the others attempted, produced an effect of long duration, which may be due to continual firing from a hypothalamic circuit, or a cortico-hypothalamic reverberation, or both. It is unlikely that the differences in duration of response are due to end-organ characteristics, since other nervous pathways to the kidney produce a shorter response. Other cortical stimulations[5] have produced similar results.

The respiratory quotient of the kidney remained at about 0·90–1·00 before and after stimulation, so that the kidney appeared to be burning mainly

GASEOUS DIFFERENCES ACROSS THE KIDNEY DURING STIMULATION

| | Gas | *A* | *B* | *C* |
|---|---|---|---|---|
| Sciatic | Oxygen<br>Carbon dioxide | 3·0<br>2·9 | 1·4<br>1·3 | 3·6<br>3·5 |
| Splanchnic | Oxygen<br>Carbon dioxide | 3·3<br>3·5 | 1·2<br>1·8 | 3·8<br>3·5 |
| Craniectomy | Oxygen<br>Carbon dioxide | 4·1<br>3·8 | 3·9<br>3·5 | 3·9<br>3·5 |
| Supra-orbital cortex | Oxygen<br>Carbon dioxide | 3·9<br>3·5 | 2·7<br>2·2 | 2·8<br>2·3 |

*A* = before stimulation; *B* = during stimulation; *C* = after stimulation carbohydrate, and stimulation had little effect on this process.

---

* Present address, Department of Experimental Medicine, University of Cambridge.

The decreases in arterio-venous oxygen and carbon dioxide differences reported here would indicate either an increased total flow, or a decreased distribution of flow, or both. A decreased distribution of flow would be followed by an increased flow in the non-compromised portions, if the total flow remained constant. An example of this is the by-pass described by Trueta *et al.*[6]. Cessation of flow of urine may be attributed to a decreased effective blood supply to glomeruli and tubules by direct afferent arteriolar vasospastic action. Such an afferent arteriolar change would also produce the suggested redistribution or redirection of flow within the vascular network and is in agreement with recent clearance data[7] showing the renal response to stimulation.

I should like to express my gratitude to Profs. D. H. Barron and J. F. Fulton for direction and advice, and to Prof. R. A. McCance, who aided in the preparation of this communication. The fluoroscopy unit was lent by Dr. Samuel Gelfan. This work was financed by a grant from the Therapeutic Research Committee of the American Medical Association.

# CALCULATION OF ELECTRON-DENSITY DISTRIBUTION IN CRYSTALS WITH THE HELP OF CONVOLUTION OPERATIONS

By R. HOSEMANN
Kaiser-Wilhelm-Institut for Physical Chemistry, Berlin-Dahlem
AND
S. N. BAGCHI*
University College of Science, Calcutta

THE electron density distribution $\rho_\infty$ of an infinitely large crystal is usually represented by a Fourier series,

$$\rho_\infty(x) = \frac{1}{v_r}\sum_{h}^{\infty} f(b_h)\exp 2\pi i(b_h x), \tag{1}$$

where

$$b_h = h_1 b_1 + h_2 b_2 + h_3 b_3, \tag{2}$$

and

$$b_1 = \frac{[a_2 a_3]}{v_r},\quad b_2 = \frac{[a_3 a_1]}{v_r},\quad b_3 = \frac{[a_1 a_2]}{v_r}$$

and

$$v_r = (a_1 a_2 a_3) = \frac{1}{(b_1 b_2 b_3)}. \tag{3}$$

$a_1$, $a_2$, $a_3$ and $b_1$, $b_2$, $b_3$ are the three fundamental-vectors of lattice cells having the volume $v_r$ in physical space and $1/v_r$ in Fourier space, $(bx)$ denotes the scalar product of radius vectors $x$ and $b$ in physical and reciprocal spaces respectively, the Miller indices $h_1$, $h_2$, $h_3$ are integers and $b_h$ represents the co-ordinate of the reciprocal lattice point $h$. The Fourier coefficients $f(b_h)$ are known as structure amplitudes; they are, in general, dimensionless complex numbers, but are real for $\rho_\infty$ having a centre of symmetry. Only the magnitude $|f(b_h)|$ is obtained experimentally from the integral intensity of the crystal reflexion lying at $b_h$. The difficulty and uncertainty of determining $f(b_h)$ itself from the $|f(b_h)|$ value are well known in classical X-ray crystallography (cf. Hosemann and Bagchi[1]). As in Fourier analysis, here it will also be asumed that the problem of the determination of phases has been satisfactorily solved, and $f(b_h)$ values are known. Even then, the calculation of $\rho_\infty$ with the help of eq. (1) is a laborious task, and various methods and machines have been suggested to lighten this burden (cf. Booth[2] and Nowacki[3]). Moreover, so calculated, $\rho_\infty$ has the following disadvantages.

(*a*) It is very difficult (if at all possible) to discuss the errors involved in the calculated $\rho_\infty$ resulting from errors in measured values of $f(b_h)$.

(*b*) Since experimentally only the reflexions lying within the sphere

$$|b_h| < 2/\lambda \tag{4}$$

can be measured, $\lambda$ being the wave-length of X-rays, the number of terms in eq. (1) would be at most

$$H = \frac{4\pi}{3}\left(\frac{2}{\lambda}\right)^3 v_r. \tag{5}$$

Thus, the calculated

$$\rho_{\text{Abb.}} = \frac{1}{v_r}\sum_{h=0}^{H} f(b_h)\exp 2\pi i(b_h)x \tag{6}$$

shows contour lines of equal electron-density distribution which are different from those of true $\rho_\infty$. This distortion due to the termination of series ('Abbruch effect') cannot be exactly calculated with the help of existing methods. But this is particularly important in view of the fact that the distortion is most marked in the region (as has been shown here) which is likely to offer valuable information about the nature of valence bonds.

(*c*) This 'Abbruch effect' also causes a displacement of the co-ordinates of the atoms, which cannot be exactly calculated.

The following method of calculation overcomes or reduces all these difficulties, since here the major portion of the intensity is treated with the convolution operation to give a $\rho(x)$, and the few remainder terms, when not negligible, can be treated in the usual way of Fourier synthesis.

Let $P^1(b - b_h)$, $P^1(x - x_s)$ denote point functions such that

$$\begin{aligned} P^1(b - b_h) &= 0 \quad \text{for } b \neq b_h \\ P^1(x - x_s) &= 0 \quad \text{for } x \neq x_s \\ \int P^1(b - b_h)\,dv_b &= 1 \\ \int P^1(x - x_s)\,dv_x &= 1, \end{aligned} \tag{7}$$

$dv_b$ and $dv_x$ being elements of volume in Fourier and physical space, respectively.

Further, let the crystal lattice be represented by the lattice peak function $z^1$ and the reciprocal lattice by the lattice peak function $Z^{1/v_r}$ (cf. Ewald[4]), such that

$$Z^{1/v_r}(b) = 1/v_r \sum_{h}^{\infty} P^1(b - b_h)$$

and

$$z^1(x) = \sum_{p}^{\infty} P^1(x - x_p). \tag{8}$$

---

* Present address: Kaiser-Wilhelm-Institut for Physical Chemistry, Berlin-Dahlem.

$x_p = p_1a_1 + p_2a_2 + p_3a_3$ denotes the position of the middle point of the crystal lattice cell $p$.

Moreover, let $\overbracket{g_1g_2}$ or $\overbracket{G_1G_2}$ denote the convolution (*Faltung*) product of two functions $g_1$ and $g_2$ in physical space or $G_1$ and $G_2$ in reciprocal space, so that

$$\overbracket{g_1g_2}(x) = \int g_1(y)\, g_2(x-y)\, dv_y \tag{9}$$

and

$$\overbracket{G_1G_2}(b) = \int G_1(c)\, G_2(b-c)\, dv_c.$$

For fixed values of $x$ or $b$, the integration is to be extended over all space.

The convolution theorem of Fourier transformations states that

$$\mathcal{F}\, \overbracket{g_1g_2} = G_1G_2$$

and

$$\mathcal{F}\,(g_1g_2) = \overbracket{G_1G_2} \tag{10}$$

where $G_1 = \mathcal{F}\,(g_1)$ ; $G_2 = \mathcal{F}\,(g_2)$.

Now, using eq. (8), the summation (1) can be represented as a Fourier integral $\mathcal{F}^{-1}$, as follows:

$$\rho_{\infty}(x) = \mathcal{F}^{-1}\,(f'Z^{1/v_r}) = \int f'(b)\, Z^{1/v_r}(b) \exp\,[2\pi i(bx)]\, dv_b, \tag{11}$$

where $f'(b)$ is any arbitrary function (requiring only to be partially smooth and free from singularities) in Fourier space, which need only to have the given values of $f(b_h)$ at points $b = b_h$, that is,

$$f'(b) = f(b_h) \text{ at points } b = b_h. \tag{12}$$

In choosing the nature of the function $f'(b)$, one should consider the convenience of further calculation.

The convolution theorem of Fourier transformations (eq. 10) allows eq. (11) to be expressed as

$$\rho_{\infty}(x) = \overbracket{\rho'\, z^1} = \int \rho^1(y)\, z^1(x-y)\, dv_y, \tag{13}$$

where

$$\rho'(x) = \mathcal{F}^{-1}\,(f') = \int f'\,(b) \exp\,[2\pi i(bx)]\, dv_b. \tag{14}$$

The convolution product (13) is independent of the nature of the function $\rho'(x)$ so long as its Fourier transform $f'(b)$ fulfils eq. (12). In Fourier space this is evident from (11), since $f'(b)$ is multiplied by a lattice peak function $Z^{1/v_r}$, which has zero values outside $b = b_h$ (cf. Ewald[4]). In physical space, however, the correctness of (13) and (14) seems at first to be paradoxical, but can be proved as shown below.

The integral (13) can be written as

$$\overbracket{\rho' z^1} = \lim_{b\to 0} \mathcal{F}\,(\rho'(y)\, z^1(x-y)). \tag{15}$$

Using the shift theorem of Fourier transformations, we have

$$\mathcal{F}\,(z^1(x-y)) = \int z^1(x-y) \exp\,[-2\pi i(by)]\, dv_y = Z^{1/v_r} \exp - 2\pi i(bx).$$

Substituting $\rho'$ and $z^1$ for $g_1$ and $g_2$ respectively in eq. (10), we have from (15)

$$\overbracket{\rho' z^1} = \lim_{b\to 0} \overbracket{f'\,(Z^{1/v_r}} \exp - 2\pi i(bx)). \tag{16}$$

Since

$$\lim_{b\to 0} \overbracket{f'\,(P^1\,(b-b_h)} \exp - 2\pi i(bx)) = f'(b_h) \exp 2\pi i(b_hx), \tag{17}$$

the identity

$$\rho_{\infty}(x) = \overbracket{\rho' z^1} = \sum_{p}^{\infty} \rho'(x + x_p), \tag{18}$$

with

$$x_p = p_1a_1 + p_2a_2 + p_3a_3$$

($p_1$, $p_2$, $p_3$ being integers) follows from (16) and (17) as soon as (12) is fulfilled.

As an example, the structure of sodium chloride at room temperature has been analysed in the following steps.

(i) A smooth curve is drawn through all the experimentally obtained values of $f(b_h)$ for $(h_1, h_2, h_3) = (200), (220), (420)$, etc., and another one through the values $f(b_h)$ of (111), (131), (133), etc.

(ii) These curves are extrapolated also for $|\,b\,| > 2/\lambda$, either after Hartree[5] or by plotting $\ln f'$ against $b^2$ and then extrapolating linearly.

(iii) Only in the case of reflexions having different values of $f(b_h)$ for the same $|b| = |b_h|$ is a deviation of $f'(b)$ from spherical symmetry postulated. In that case, either one can interpolate a non-spherically symmetrical curve $f'_n(b)$ or, more conveniently, one interpolates a spherically symmetrical $f'_s(b)$, and the remaining few parameters

$$\Delta_1 f'(b_h) = f'_n(b_h) - f'_s(b_h) \tag{19}$$

are separately treated as correction terms.

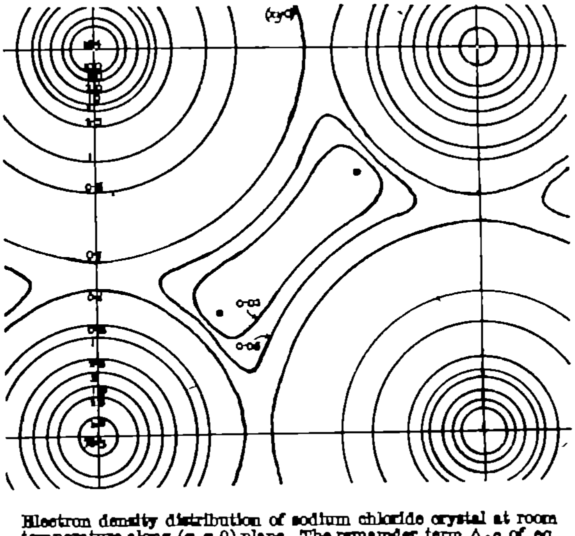
(iv) In spite of the fact that $f(b_h)$ has only one particular value for any constant value of $|b_h|$, a few values of $f|(b_h)|$ may deviate from a conveniently smooth interpolated curve $f'_s(b)$ (that is, a wavy form of $f'(b)$ in the radial direction). In this case also, one can either interpolate this wavy function $f'_w(|b|)$ or, again more conveniently, take the smooth curve $f'_s(b)$ and introduce the deviations

$$\Delta_2 f'(b_h) = f'_w(b_h) - f'_s(b_h) \tag{20}$$

as correction terms.

The spherically symmetrical $f'_s(b)$ function, when transformed into physical space, gives spherically symmetrical density distributions $\rho'_s$ around certain points $x_s$ in the crystal cell, which are determined by the special structure of the crystal.

The overlapping of the spherically symmetrical distributions $\rho'_s(x - x_s)$ around such adjacent lattice



Electron density distribution of sodium chloride crystal at room temperature along $(p_1p_2 0)$ plane. The remainder term $\Delta_2\rho$ of eq. (20) affects only the contour lines $\not< 0{\cdot}03$ electrons/Å.$^3$

points $x_n$, if any, causes a deviation from spherical symmetry inside the lattice cell. Actually, such deviations were found in the case of sodium chloride (see diagram), though $f'$-values were spherically symmetrical.

(v) The advantage of deciding in favour of a spherically symmetrical function $f'_s(b)$ is that it can easily be transformed by one-dimensional Fourier analysis:

$$\rho'_s(r) = \frac{4\pi}{r}\int_0^\infty |b|\, f'_s(|b|) \sin 2\pi r|b|\, d|b|\,;\quad r = |x|. \quad (21)$$

(vi) The advantage of using a smooth function $f'_g(b)$ lies in the fact that it can be resolved into a few Gaussian curves $G(b)$ the Fourier transforms of which can be calculated directly. Thus

$$f'_g(b) = \sum_{n=1}^{N} A_n\, G_n(b)$$

with

$$G_n = \pi^{3/2}\, c_r c_s c_t \exp - \pi^2 (c_r^2 b_r^2 + c_s^2 b_s^2 + c_t^2 b_t^2) \quad (22)$$

and

$$\rho'_g(x) = \sum_{n=1}^{N} A_n\, g_n(x)$$

$$g_n(x) = \exp(-x_r^2/c_r^2 - x_s^2/c_s^2 - x_t^2/c_t^2), \quad (23)$$

where $b_r$, $b_s$, $b_t$ and $x_r$, $x_s$, $x_t$ are orthogonal components of $b$ and $x$, and $c_r = c_s = c_t$ in the case of spherical symmetry.

(vii) The required electron density distribution is then given by

$$\rho_\infty(x) = \rho'_{gs} \sqcap z^1 + \Delta\rho(x), \quad (24)$$

where the Fourier transform of $\rho'_{gs}$ is smooth as well as spherically symmetrical, and the remainder term $\Delta\rho$ can be easily calculated, since

$$\Delta\rho(x) = \frac{1}{v_r}\sum_{h}^{H} (\Delta_1 + \Delta_2)\, f(b_h) \exp 2\pi i(bx). \quad (25)$$

In the case of sodium chloride the electron-density distribution is given by

$$\rho_\infty(x) = \left(\frac{\rho'_1 + \rho'_2}{2}\right) \sqcap z''(x) + \left(\frac{\rho'_1 - \rho'_2}{2}\right) \sqcap z''\left(x - \frac{a_1}{2}\right) + \Delta_2\rho, \quad (26)$$

where the Fourier transforms of $\rho'_1$ and $\rho'_2$ are smooth and spherically symmetrical, $z''(x)$ is a face-centred lattice and $z''(x - a_1/2)$ is the same lattice with its origin shifted to $a_1/2$. $\Delta_1\rho = 0$, because every $|b_h|$ has one and only one value of $f(b_h)$ and $\Delta_2\rho$ is negligible almost in the whole of the lattice cell.

The electron-density distributions calculated from equation (26) along (100), after taking into account respectively Hartree's linear extrapolation for $|b| > 2/\lambda$ (ref. 5) and the logarithmic method mentioned above, show a discrepancy which is less than 4 electrons/A.³ near the centres of Na+ and Cl− ions and negligible outside the region $r = 0{\cdot}3$ A. from the centre of each ion (the difference is less than 0·001 electrons/A.³).

On the contrary, if it is taken that $f(b_h) = 0$ for all $|b| \geqslant 2/\lambda$, as is generally assumed in usual Fourier synthesis, the 'Abbruch effect' is not negligible outside $r = 0{\cdot}3$ A.; in the case of molybdenum $K\alpha$-radiation the contour lines are distorted by $\Delta\rho_{\rm Abb}$-waves of length ∼ 0·4 A. and amplitudes ∼ 0·5 electrons/A.³, lying at the outer shells of the atoms, and ∼ 0·1 electrons/A.³ in the centre of neighbouring ions. This causes the well-known displacement of the centres.

This 'Abbruch effect' can also be calculated with the help of convolution operations. Since

$$f'(b)_{\rm Abb.} = f' \cdot S\,;\quad \rho'_{\rm Abb.} = \rho' \sqcap s, \quad (27)$$

S($b$), the Abbruch-shape function in Fourier space, is a sphere of radius

$$|b| = 2/\lambda = B, \quad (28)$$

and of density unity. Since

$$s(r) = \mathcal{J}^{-1}(S) = \frac{4\pi}{3} B^3 . 3\, \frac{\sin 2\pi Br - 2\pi Br \cos 2\pi Br}{(2\pi Br)^3}, \quad (29)$$

$\rho'(r)_{\rm Abb.}$ shows according to (27) subsidiary maxima at distances of about $r \sim 1/B = 0{\cdot}36$ A. for molybdenum $K\alpha$-radiation. The diagram represents $\rho_\infty(x)$ along $(p_1 p_2 0)$ planes, which is obtained by using the logarithmic method of extrapolation. $\Delta_2\rho$ only causes a correction (see eq. 25) of less than 0·02 electrons/A.³ and affects only the region of the small island in the diagram between two adjacent chlorine ions.

The maximum possible errors in the calculated values of $\rho_\infty$ can also be easily determined. $\rho_{\rm Na^+}$ and $\rho'_{\rm Cl^-}$ can be calculated sufficiently accurately from curves of $\ln f'/b^2$ with the help of eq. (23) and (26). They are composed of two and three $g_n(r)$, respectively.

Given the type of structure (eq. 26) and the lattice edge $|a_1| = |a_2| = |a_3| = 5{\cdot}618$ A., the whole of the sodium chloride structure at room temperature can be described by the ten following parameters only (cf. eq. 23):

| $n$ | | $A_n$ (electrons/A.³) | $c_n$ (A.) |
|---|---|---|---|
| $\rho'_{\rm Na^+}$ | 1 | 13·2 ± 0·6 | 0·449 ± 0·006 |
| | 2 | 57·0 ± 3·0 | 0·220 ± 0·003 |
| $\rho'_{\rm Cl^-}$ | 1 | 1·8 ± 0·2 | 0·89 ± 0·02 |
| | 2 | 4·9 ± 0·6 | 0·46 ± 0·02 |
| | 3 | 167 ± 8 | 0·210 ± 0·002 |

It is very interesting to note that Na+ with two electron shells can be described by the summation of two, and Cl− with three, electron shells by means of three Gaussian curves $A_n g_n(r)$ (cf. eq. 23); this may not be merely an accident.

We wish to thank Prof. H. Witte and Dr. E. Wölfel (Institut für chemische und physikalische Röntgenkunde, Darmstadt) for placing their experimental data of $f(b_h)$ at our disposal (cf. Wölfel[6]). The calculations necessary to give the results shown in the table were carried out by F. Motzkus and G. Schoknecht in two days without the help of any machine, for which also our thanks are due. It is hoped to publish this work in full in the near future.

## Quaternary Derivatives of Benzoyltropine and Benzoyl-ψ-tropine with Anticholinergic and Local Anæsthetic Properties

In the course of experiments dealing with correlations between structure and effect of cholinergic-blocking (antimuscarine, antinicotinic) actions[1,2], it has been found that in the case of compounds with tropeine structure the influence exerted on the effects by different quaternary groups shows great variations. Quaternary derivatives of tropeines possessing local anæsthetic properties, for example, benzoyltropine (= benzoyl-anti-tropine)[3], as well as benzoyl-ψ-tropine (= benzoyl-syn-tropine), have been prepared and studied[4], special consideration being given to the correlations between stereo-structure and pharmacological effect. Antimuscarine, ganglionic-blocking, curare-like, as well as local anæsthetic actions have been investigated. The effects of the individual compounds are shown in the accompanying table.

| | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|
| Benzoyltropine HCl | 0·01 | < 0·1 | — | 1·5 | |
| ,, $CH_3I$ | 0·025 | 2·1 | 0·15 | 0·6 | |
| ,, $C_2H_5Br$ | 0·02 | 3·0 | 0·25 | 1·4 | |
| ,, $n$-$C_3H_7Br$ | 0·02 | 2·8 | < 0·10 | 1·2 | |
| ,, $n$-$C_4H_9Br$ | 0·005 | 6·0 | 0·25 | 0·6 | |
| ,, benzyl Br | 0·01 | 3·0 | 0·10 | 1·2 | |
| Benzoyl-ψ-tropine HCl | 0·003 | < 0·1 | — | 2·2 | 2·6 |
| ,, $CH_3I$ | 0·002 | < 0·2* | < 0·06 | 0·25 | 0·4 |
| ,, $C_2H_5Br$ | 0·005 | 6·7 | 0·15 | 0·58 | 2·8 |
| ,, $n$-$C_3H_7Br$ | 0·003 | 6·0 | 0·10 | 0·80 | 3·0 |
| ,, $n$-$C_4H_9Br$ | 0·005 | 4·6 | 0·25 | 1·50 | 3·2 |
| ,, $i$-$C_5H_{11}I$ | 0·003 | 2·8 | 0·20 | 1·55 | 4·3 |
| ,, benzyl Br | 0·005 | 0·5 | 0·10 | 2·20 | 2·0 |

1. Antimuscarine effect on isolated rabbit and guinea pig intestine; atropine = 1.
2. Ganglionic blocking effect on nictitating membrane of the cat; TEA = 1.
3. Curare effect in the frog; *d*-tubocurarine = 1·0.
4. Infiltration anæsthesia on the skin of the abdomen in the rat (ref. 4); procaine = 1·0.
5. Conduction anæsthesia (frog plexus anæsthesia); procaine = 1·0.

* Ganglionic stimulating effect can also be observed.

In the case of tropeines with different stereo-structures, cholinergic-blocking effects undergo entirely different changes when quaternary groups are altered. In our opinion, when measuring anæsthetic action upon conduction, it does not suffice to use methods by means of which the motor response alone can be studied in the case of substances possessing curare activity. The derivatives we used, however, show marked activity from the point of view of infiltration anæsthetic action as well. Thus the higher alkyl, as well as aralkyl, quaternaries show activities similar to those of tertiary compounds. This effect could be observed in the case of other tropeines and other aralkyl quaternaries—for example, α-naphthylmethyl, 1-4-xylylene, as well[5]. This means that the generally accepted view, according to which local anæsthetic action of amines is confined to compounds containing secondary or tertiary amino groups, is not valid. The above view gained general acceptance most probably owing to the fact that it was mainly methyl quaternary compounds that had been studied. The methyl quaternaries have proved to be relatively inactive in the present investigations.

In our opinion, the syn- or anti-position of the OH group of tropine and the aromatic ester group bound to it[3], as well as the character of the quaternary groups, interact to influence the total stereo-structure of the compound, and thus secure the optimal molecular structure required for the different pharmacological effects[5].

Local anæsthetic action of quaternary tropeines showing anticholinergic effect suggests that the local anæsthetic action (using the term in a general sense) should be considered to be an anticholinergic effect.

## Synthesis of Quaternary Compounds possessing Lasting Local Anæsthetic Action

It has been found that, when compounds with local anæsthetic action containing tertiary nitrogen and belonging to different types of compounds are transformed into alkyl-, but especially into aralkyl-, quaternary derivatives, then the new compounds invariably exhibit a slowly developing local anæsthetic action that, however, is of very long duration. Nádor and Gyermek have found that ganglionic blocking[1] and curare-like action[2] of quaternary compounds are to a great extent dependent upon the type of chain the nitrogen is quaternarized with; therefore alkyl- and aralkyl-quaternary compounds have been used in our experiments.

Synthesis of quaternary compounds has been carried out in the following way. The tertiary compound is brought into reaction in benzene or acetone with the proper alkyl- or aralkyl-halogenide; the reaction proceeds smoothly, but care must be taken to exclude even traces of humidity. In this way, among others, diethyl-benzyl-4-(amino-benzoyl)-β-oxyethyl-ammonium bromide, that is, procaine-brombenzylate, was obtained by the reaction of *p*-amino-benzoic acid-β-diethylaminoethylester and benzyl bromide; melting point, about 120° indefinite; markedly hygroscopic. $C_{20}H_{27}O_2N_2Br$ requires C, 59·65; H, 6·68; N, 6·87; Br, 19·62 per cent; found: C, 59·32; H, 6·66; N, 6·74; Br, 19·60 per cent.

Similar methods have been used for the preparation of pantocaine-brombenzylate from methanol-ether (melting point, 168–70°), and nupercaine-brombenzylate from ethanol-ether (melting point, 183–85°).

Methyl-quaternary derivatives were prepared in the same way. The compounds dissolve readily in water and are stable. Novocaine-brombenzylate decomposes in water, a small amount of benzyl bromide being set free when exposed to prolonged standing.

Compounds have been synthesized in other ways as well, and thus evidence has been obtained that the quaternarizing alkyl or aralkyl chain was invariably added to the β-dialkyl-aminoalkyl side-chain. For example, the *p*-nitrobenzoic acid-β-bromethylester, obtained by means of esterizing glycolbromhydrine with benzoylchloride, gave with diethylbenzylamine the quaternary *p*-nitrobenzoyl ester, which, when hydrogenized in ethanol, resulted in a compound identical with the novocaine-brombenzylate already mentioned.

Further evidence of the general validity of the phenomenon is to be seen also in the fact that not only the typical local anæsthetics mentioned, but also compounds of other types as well, completely follow in their quaternary derivatives the local anæsthetics. The latter compounds, to which belong, for example, the parasympathetic blocking agents atropine and diphenylpiperidino acetamide[3], and also pyribenzamine possessing antihistaminic effect, were found to exert, in addition to the effects mentioned, also more or less marked local anæsthetic action in their tertiary forms. These compounds have been produced by the method already described.

The experiments have been extended to a variety of different alkyl, cycloalkyl and aralkyl derivatives, as well as to local anæsthetics of different types. Synthesis of these compounds is being carried out.

According to views accepted generally hitherto[4], tertiary local anæsthetics would lose their local anæsthetic effect following quaternarization. In the case of quaternary compounds the effect usually develops only after a period of about 30 min. (obviously this is the reason why these compounds have been considered to be ineffective); but in numerous cases it is 12–16 hr. before the effect develops. Methyl-quaternary derivatives are generally less effective than are corresponding tertiary compounds; but even the latter are sometimes surpassed by aralkyl derivatives.

Local anæsthetic effect as determined by means of pharmacological investigations[5] of a few characteristic compounds from among the numerous quaternary derivatives are shown in the accompanying table.

| Compounds | | Conduction | Infiltration |
|---|---|---|---|
| | | Local anæsthetic action | |
|  <br>Procaine | tertiary | 1 | 1 |
| | methyl-quaternary | 0·9 | 0·9 |
| | benzyl-quaternary | 2·4 | 6·5 |
|  <br>Pantocaine | tertiary | 6·4 | 8·6 |
| | methyl-quaternary | 2·8 | 7·5 |
| | benzyl-quaternary | 5·1 | 27·0 |
|  <br>Nupercaine | tertiary | 16·0 | 21·4 |
| | methyl-quaternary | 8·1 | 14·9 |
| | benzyl-quaternary | 11·7 | 15·6 |

Details of this investigation will be published in *Acta Chimica Hungarica*. We are grateful to the Hungarian Academy of Sciences for substantial aid and to Miss Magda Markó for assistance with the experiments.

## An Olfactometer for observing the Behaviour of Small Animals

ONE of the earliest olfactometers was the *Y*-tube type devised by Barrows in 1907[1]. Illustrations of several modifications to this basic design of apparatus are given by Dethier[2]. A difficulty arises in the use of these designs because of the sharp line of demarcation between the odours[3] at the junction of the two arms. On reaching this point, the animal is suddenly confronted with a choice, and has little chance of rectifying a 'mistake' as it is confined to a short narrow tube, at the end of which it is trapped. The relative attractiveness of two odours is estimated by observing the numbers of animals which choose each arm of the *Y*, and there is little or no opportunity for studying other changes in behaviour initiated by the odours.

Thorpe *et al.*[4] studied the chemotropic responses of wireworms in a chamber partly filled with sand over which a stream of air was passed. A longitudinal partition reaching almost to the level of the sand divided the air in the upper part of the chamber into two sides which could each be given a characteristic smell. Although there was little mixing of the gases, the wireworms could pass freely from one side to the other, and their response was judged by counting the number which burrowed into the sand on each side. This is, in effect, a choice chamber in which only the end result is observed.

A new and very simple olfactometer has been designed which consists of a wide flat glass chamber, through which is passed a current of air. The flatness of the chamber minimizes turbulent mixing, and a known part of the air stream can be contaminated with the odour to be tested. The animal's movements and behaviour can be observed and timed as it wanders freely across a known gradient.

Six narrow strips of plate-glass were arranged to form the walls of a hexagonal chamber between two sheets of plate-glass. For the study of the behaviour of the blow-fly parasite *Mormoniella vitripennis* (Walk.) (Hymenoptera, Chalcidoidea), which is about 2·5 mm. in length, a chamber 40 cm. × 16 cm. was used (Fig. 1). The insects were introduced through one arm of a *T*-shaped entrance tube. A rate of flow of approximately 60 cm./min. was used, and smoke trails showed that the airstreams down

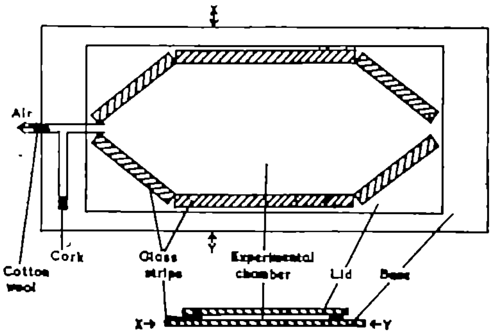

Fig. 1. Plan of the olfactometer, and a cross-section through *XY*

the broadest part of the apparatus were then parallel. The effects of diffusion were observed by drawing ammonia fumes over a smear of hydrochloric acid placed on the shaded square in Fig. 2. The limits of the area covered by the ammonium chloride are shown by the dotted line.

The odoriferous substance to be tested was placed on the shaded square and a single insect introduced through the entrance tube. The track taken by the insect was recorded on a piece of squared paper, arrow-heads being marked at 15-sec. intervals. Each experiment was continued for five minutes or until the insect walked out of the apparatus, whichever occurred first.

In the control experiments, when no odour was present, female *Mormoniella* walked straight through the apparatus. When subjected to the odour of liver on which blow-fly larvæ had been feeding, they remained in the contaminated area and followed a twisting path which frequently led them to the source of the odour. There was no evidence that the insects received a directed stimulus, apart from the tendency to walk upwind which they displayed even when no odour was present (Fig. 2). Once within the area of contamination, the insects remained there, making frequent short-radius turns, which were, however, not confined to the margins of the contaminated area (Fig. 3). Such turns were never observed on control runs, and are to be regarded as a behaviour response to the odour of the hosts' environment.

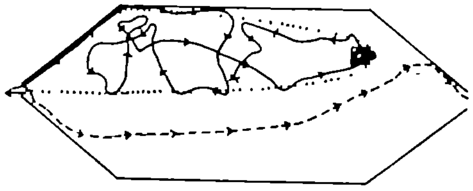

Fig. 2. Track of a *Mormoniella* female when subjected to the odour of liver on which blow-fly larvæ have fed. The dotted line shows the extent of the contaminated area; the broken line shows the track of the female during a control run, when no odour was present

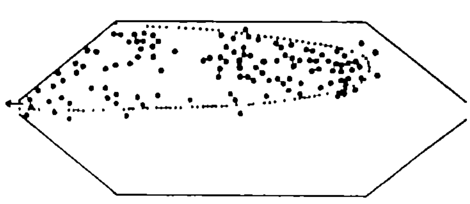

Fig. 3. Points at which *Mormoniella* females executed short-radius turns when subjected to the odour of liver on which blow-fly larvæ have fed. Dotted line shows the extent of the contaminated area. (Results from 14 experimental runs superimposed)

This type of olfactometer has the advantage of easy construction, and it can be very easily cleaned or modified. The animal's behaviour can readily be observed, and movement is less restricted than in other types of apparatus. It should be simple to modify such an apparatus for the study of aquatic animals.

## Occurrence of Vitamin E in Cod and Other Fish-liver Oils

It has been found with many different animal species that, if the diet is low in vitamin E and is supplemented with cod-liver oil, signs of vitamin E-deficiency result[1]. This observation has sometimes led to the assumption that vitamin E is not present in the oil; but the assumption has not always been confirmed by biological and chemical assays of the oil, although both methods have led to conflicting reports[2]. The following experiments were made in an attempt to clarify the situation.

Preliminary examination of three samples of cod-liver oil by the Emmerie–Engel method indicated the presence of 25·6, 30·2 and 32·2 mgm. total tocopherols in 100 gm. of the oils. Since this method is not specific for tocopherols, a fuller examination was then carried out. The unsaponifiable material, obtained from the oils by alkaline hydrolysis in the presence of pyrogallol, was freed from carotenoids, vitamin A and sterols. Chromatography of the concentrate on 'Vaseline'-coated paper, using 75 per cent ethanol or 90 per cent acetic acid as the developing solvent[3], or on silicone-impregnated paper using 70 per cent ethanol, followed by spraying with $\alpha\alpha'$-dipyridyl and ferric chloride, revealed the presence of a substance which had the same $R_F$ value as α-tocopherol under the variety of conditions described. In addition, a mixture of α-tocopherol and the concentrate gave only one spot on the developed chromatograms.

In view of these results with cod-liver oil, and the observations by Robeson and Baxter[4] that α-tocopherol occurs in two different shark-liver oils, dogfish and Californian jewfish, five other fish-liver oils have been similarly examined. The tocopherol contents are shown in the accompanying table. For each oil, examination of the paper chromatogram revealed the presence of α-tocopherol, and no other substance reducing ferric chloride was found in the concentrates. It is probable, therefore, that α-tocopherol is a normal constituent of fish-liver oils and may act as a natural antioxidant in these oils as well as in vegetable oils.

The results for cod-liver oil confirm the observations of Dam[5] and Blaxter[6] that the typical signs of vitaα-TOCOPHEROL CONTENT OF FISH-LIVER OILS

| Liver oil | α-Tocopherol (mgm./100 gm. oil) |
|---|---|
| Cod | 25·6 ; 30·2 ; 32·2 |
| Angler fish | 31·9 |
| Blue skate | 25·3 |
| Haddock | 18·0 |
| Ling | 27·2 |
| Turbot | 45·0 |

min E-deficiency produced in animals given a ration containing the oil are not due to a deficiency of the vitamin in the diet so much as to the presence of the highly unsaturated acids of the oil.

I am grateful to Dr. J. A. Lovern, of the Torry Research Station, Aberdeen, for the samples of oils.

## Rapid Production of Malignant Hepatomas by Simultaneous Administration of Tannic Acid and 2-Acetylaminofluorene

IN previous experiments we have proved the cirrhogenic[1] and carcinogenic[2] activity of tannic acid administered parenterally, and that this activity can be influenced by the protein content of the diet[3]. It seemed of interest to examine whether the simultaneous administration of another hepatic carcinogen has an influence on the carcinogenic activity of the tannic acid.

The experiment was made on fifty-six young rats of 115 gm. average body-weight divided into two groups, each group containing identical numbers of males and females. The animals of group 1 were given tannic acid solution subcutaneously once weekly (four doses of 200 mgm. per kgm. 2 per cent aqueous solution, or else 250 mgm. per kgm. 2·5 per cent aqueous solution). The diet of both groups consisted of casein 10 per cent, sunflower oil 10 per cent, cod liver oil 1 per cent, yeast 3 per cent, salt mixture 4 per cent, dextrin 22 per cent, maize grits 50 per cent. To this were added 2·5 mgm. in the first four weeks and then 3 mgm. daily per animal of acetylaminofluorene.

Of group 1 (tannic acid + acetylaminofluorene) thirteen rats died before the 160th day, of group 2 (acetylaminofluorene only) five animals died during the same period and five were killed at different times. The surviving rats were killed on the 180th day of the experiment. Primary tumours occurred only in the liver. The tumours produced could be grouped as follows : group 1, preliminary changes (that is, some changes, at most pinhead-sized nodes) ; group 2, explicit changes (tumours of 2–6 mm. diameter) ; group 3, largest growths (Table 1).

Table 1

|  | No. of rats | Rats with liver tumours (1) | (2) | (3) | Total | Per cent |
|---|---|---|---|---|---|---|
| Tannic acid and acetylaminofluorene | 28 | 7 | 15 | 4 | 26 | 92 8 |
| Acetylaminofluorene | 28 | 6 | 2 | – | 8 | 28·5 |

The largest tumour produced was 5 cm. × 3·6 cm. × 3·6 cm. in size, weighing 27·45 gm. ; this rat died on the 166th day of the experiment. The tumour proved histologically to be an anaplastic malignant hepatoma. Metastases were present in the regional lymph nodes.

It is well known that hepatomas due to the effect of 2-acetylaminofluorene administration[4] occur more frequently in males than in females. In this experiment, however, as a result of the simultaneous administration of tannic acid and 2-acetylaminofluorene, hepatomas developed in all the males and in twelve of the females, whereas acetylaminofluorene alone produced hepatomas in four male and four female rats.

The results for the simultaneous occurrence of hepatomas and cirrhosis are shown in Table 2.

Table 2

|  | Early cirrhosis | Developed cirrhosis | Total | Tumour and cirrhosis |
|---|---|---|---|---|
| Tannic acid and acetylaminofluorene | 7 | 11 | 18 | 17 |
| Acetylaminofluorene | 5 | — | 5 | 1 |

This experiment suggests that : (1) simultaneous administration of tannic acid and 2-acetylaminofluorene greatly increases the carcinogenic activity of these substances on the liver ; (2) liver cirrhosis is an important promoting factor in liver carcinogenesis.

This work will be published in detail in the *Acta Morphologica Hungarica*.

## Doubling of Chromosomes Induced by Gloriosine isolated from *Gloriosa superba*, Linn.

THE usefulness of colchicine as a chemical in doubling chromosomes in plants was first reported by Blakeslee[1], who obtained polyploids in *Datura stramonium* by treating its seeds with this alkaloid. Since then, colchicine has been extensively used for inducing polyploidy in many species of plants. In announcing an Indian source for colchicine, Parthasarathy[2] reported that, if fresh extract of tubers of *Gloriosa superba* is applied to maize seed before sowing, the developing roots show tetraploid sectors. This confirmed the polyploidizing influence of the alkaloid colchicine present in these tubers, the isolation of which had been reported by Clewer, Green and Tutin[3] in 1915.

Some months ago, tubers of *G. superba* collected from the Deccan and coastal areas of Bombay State were supplied to the National Chemical Laboratory, Poona, for extracting colchicine which was required for cytogenetic and plant-breeding work in this laboratory. During the extraction, Subbaratnam[4] reported the isolation of a new alkaloid allied to colchicine which has provisionally been named 'gloriosine'. Very small quantities of the alkaloids colchicine and gloriosine extracted from *G. superba* were made available for testing their influence in inducing polyploidy. A comparison was therefore made by testing these with colchicine obtained from *Colchicum autumnale*. 0·3 per cent aqueous solutions of the three alkaloids were prepared, and plumules of germinated seedlings of two pure varieties of sann hemp (*Crotalaria juncea*) were kept immersed in the solutions for four hours and were later washed and planted out. When the plants were in flower their ploidy was determined.

Swelling and retarded growth of seedlings treated with colchicine from *C. autumnale* and gloriosine showed that polyploidy had been induced. The percentage of polyploids obtained from each of the alkaloids is given in the accompanying table.

| Source of alkaloid | No. of seedlings treated | Polyploids | |
|---|---|---|---|
| | | Tetraploid | Octoploid |
| Colchicine from *C. autumnale* | 15 | 8 | — |
| Colchicine from *G. superba* | 15 | 5 | 1* |
| Gloriosine from *G. superba* | 15 | 11 | — |

* The ploidy of some plants in this lot has yet to be determined.

The results of the test clearly indicate that both colchicine and gloriosine from *G. superba* have a polyploidizing effect, and that gloriosine promises to be even more effective than colchicine in inducing polyploidy. Further tests on gloriosine are in progress.

## Identification of 4-Methyl-D-glucuronic Acid in *Eucalyptus regnans* Wood

MANY workers have identified the hexuronic acid components of pectins, gums and mucilages[1]. However, the uronic acid components of wood hemicelluloses have proved difficult to identify. O'Dwyer[2] and Yaramori and Tachi[3] have shown that glucuronic acid is present in the hemicelluloses of beech wood and of elm wood respectively. O'Dwyer[4,5] has obtained, from oak wood, an aldobiuronic acid containing one methoxyl group per uronic acid residue. Also, Sands and Gary[6] have obtained an aldobiuronic acid from mesquite wood hemicellulose: they demonstrated that the aldobiuronic acid contained a methoxyl group and, because of the difficulty encountered in the identification of the uronic acid (viewed in the light of the experience of Anderson and Otis[7]), suggested that the methoxyl group was attached directly to the uronic acid residue.

White[8] and Smith[9] have shown, by different methods, that the acid hydrolysate from mesquite gum (an exudate from mesquite wood) contains 4-methyl-D-glucuronic acid residues.

It has now been demonstrated that the acid hydrolysate from *Eucalyptus regnans* F. v. M. wood also contains 4-methyl-D-glucuronic acid residues. *E. regnans* shavings were hydrolysed with *N* sulphuric acid and the hydrolysate was neutralized with barium carbonate, filtered and concentrated. The barium salts (consisting chiefly of barium aldobiuronate) were isolated by repeated precipitation from aqueous ethanol, and the crude product (Ba, 16 per cent; uronic acid anhydride, 38 per cent; $OCH_3$, 6 per cent) was refluxed for 20 hr. with 8 per cent methanolic hydrogen chloride. The resulting crude methyl glucuronoside syrup (b.p. 132°–136° (bath temp. 185°)/0·1 mm., $n_D^{25}$ 1·48, $[\alpha]_D^{20} + 88°$ in methanol (*c*, 2·8), 29·2 per cent $OCH_3$) was then treated according to Smith[9] to give the amides of 4-methyl methyl-α- and -β-D-glucuronosides. (α-form, m.p. 232°, $[\alpha]_D^{22} + 152°$ in water (*c*, 0 36): β-form, m.p. 228°, $[\alpha]_D^{21} - 62°$ in water (*c*, 0·25).) The mixed α- and β-forms, on analysis, gave: C, 43·37; H, 6·75; O, 42·8; N, 6·51; $OCH_3$, 27·46 per cent; $C_8H_{15}O_6N$ requires C, 43·46; H, 6·84; O, 43·40; N, 6·33; $OCH_3$, 28·06 per cent. Both forms of the amide gave X-ray powder diffraction diagrams the lines of which were identical with those of samples obtained through the courtesy of Dr. F. Smith.

In addition, it was shown that D-xylose (characterized as its dibenzylidene dimethyl acetal, m.p. 211° not depressed on admixture with a sample prepared from authentic D-xylose) was also present in the mother liquors resulting from the crystallization of the mixed amides and, further, that the crude barium aldobiuronate contained no glucosidic methoxyl groups. Hence it is probable that the non-resistant carbohydrate fraction of *E. regnans* wood contains residues of the aldobiuronic acid, 4-(4-methyl-D-glucuronosyl)-D-xylose.

Since this work was completed, our attention has been directed to a paper by Jones and Wise[10], who have shown that the acid hydrolysate from aspen wood contains 4-methyl-D-glucuronic acid.

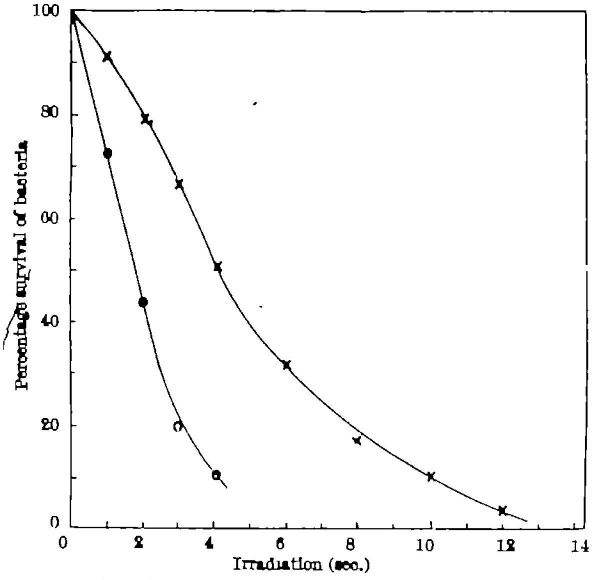
## Susceptibility of Catalase-negative Bacteria to Ultra-violet Irradiation

In the tribe Lactobacteriaceae there are two closely related genera—*Lactobacillus*, which are catalase-negative, and *Microbacterium*, which are catalase-positive. Representative members of these genera were selected, namely, *Lactobacillus pastorianus* (ATC 8291) as the catalase-negative bacteria and *Microbacterium flavum* (ATC 10340) as the catalase-positive bacteria. Both species form distinct colonies and have an optimum temperature near 30° C. The bacteria were reared on Difco's stock culture broth media and buffered with calcium carbonate, and incubated for seven to nine days at 30° C. *L. pastorianus* was diluted 1–10,000 and *M. flavum* 1–50,000 with physiological salt solution, and 1 ml. of the solution placed in the centre of a sterile Petri plate. The aliquot was exposed to ultra-violet radiation from a 40-watt tube, model HUVM-30 (American Sterilizer Co., Erie, Pa.), with about 90 per cent of the radiation at 2537 A. The distance from the tube to the bacteria was 43 cm. and time of exposure was at various intervals from 1 to 14 sec. Thirty plates were run for each time of irradiation, and average results are presented in the accompanying graph. Immediately after irradiation, 15–20 ml. of tomato agar was added to the plate and agitated to distribute the bacteria uniformly around the plate. The plates are incubated for seven days at 30° C. and the colonies counted. Controls were those bacteria which were not exposed to ultra-violet radiation.

The catalase-positive bacteria, *M. flavum*, is more resistant to ultra-violet radiation than the catalase-negative, *L. pastorianus*. Note in the graph that, after 4 sec. exposure to ultra-violet light, 50 per cent of *M. flavum* survive while only 10 per cent of *L. pastorianus* are viable.

Even after 1 sec. exposure there is a 20 per cent difference in survival, with *L. pastorianus* being more susceptible. These results would indicate that catalase does afford some protection from death by irradiation by decomposing the harmful peroxides which are produced, for the chief difference between the species is the presence or absence of catalase. The negative rate of change of the slope of the curve for *M. flavum* in the graph indicates that an enzymatic reaction of the second order is influencing the survival-rate.



×—×—, *Microbacterium flavum* ; ○—○—, *Lactobacillus pastorianus*

Survival-rates of catalase-negative *Lactobacillus pastorianus* and the catalase-positive *Microbacterium flavum* for similar periods of irradiation

## Mitochondrial Distribution in Saccharomyces

Genetical experiments by Ephrussi and co-workers[1] have adequately demonstrated the existence of extra-chromosomal factors determining the cytochrome oxidase and succino-dehydrogenase activities of yeast clones analysed by them. A particulate nature was ascribed to these factors, and their identity with the mitochondria was suggested in view of the well-known association of the enzymes concerned with these bodies; however, no direct observations on the behaviour of the mitochondria during cell divisions were reported.

In spite of their very small size, the mitochondria of actively dividing yeast constitute the most prominently visible entities of the cytoplasm and are, moreover, not obscured by any other cytoplasmic inclusions. They are recognized by their extraordinarily uniform diameters, their ability to react with the 'Nadi' reagent and with tetrazolium, and by their staining with janus green *B*. Phase-contrast microscopy reveals them with unusual clarity in the living cell, making their behaviour and distribution in budding cells amenable to direct analysis. Table 1 indicates the frequencies of mitochondria in single haploid cells, of monosporic derivation, observed in the microscope field at random. The mitochondrial counts were made under bright contrast with Kohler method illumination and a yellow-green filter. All levels within the cell were carefully focused in succession to ensure a precise count.

The variation in frequency from 1 to 18 per haploid cell bore no relation to the differences in sizes of cells normally occurring in any actively proliferating culture. Thus, for example, small single

Table 1

| No. of mitochondria per cell | No of cells counted | Percentage of cells |
|---|---|---|
| 1 | 22 | 3 8 |
| 2 | 40 | 6·9 |
| 3 | 42 | 7 3 |
| 4 | 80 | 13 9 |
| 5 | 36 | 6 3 |
| 6 | 164 | 20 8 |
| 7 | 26 | 4 5 |
| 8 | 78 | 13·5 |
| 9 | 10 | 1·8 |
| 10 | 26 | 4 5 |
| 11 | 6 | 1 0 |
| 12 | 16 | 2 8 |
| 13 | 2 | 0 3 |
| 14 | 28 | 4 9 |
| 15 | 4 | 0 7 |
| 16 | 4 | 0·7 |
| 17 | 0 | 0 |
| 18 | 2 | 0 3 |
|  | 576 | 100 |

cells (apparently buds that separated early from the mother cell) possessed one to four mitochondria; similarly, larger single cells possessing only one mitochondrion were not uncommon. It will be noted that the number most commonly encountered is six per cell and that cells with four and eight mitochondria occur in equal frequencies, constituting half the percentage of those containing six per cell; also, that even numbers of mitochondria are more frequently encountered than odd numbers, indicating that binary divisions occur once the mitochondria enter the bud.

Direct observation of the migration of mitochondria during budding is possible with phase contrast when cells are mounted in nutrient fluid. A single mitochondrion, invariably found in the mother cell at the point of attachment of the incipient bud, enters the bud at a very early stage after performing energetic movements (usually at 10 min.). This may be followed by the entry of additional mitochondria as the bud grows, but divisions of mitochondria in the mother cell to supply the bud have not been observed though such undoubtedly occur. Fusions between mitochondria have not been observed. Table 2 indicates the distribution of mitochondria between mother cells and attached buds at various stages of bud growth. The sizes of buds relative to the mother cell are arbitrarily determined as ¼, ½, ¾ and equal. Only a few representative cases among many observed are shown.

Table 2

| No. of mitochondria in mother cell | No. of mitochondria in bud (or buds) | Size of bud (or buds) |
|---|---|---|
| 6 | 1 | ¼ |
| 14 | 4 | ½ |
| 6 | 4, 3 | ¼, ¼ |
| 6 | 1 | equal |
| 8 | 1, 1 | ¼, ½ |
| 6 | 2 | ½ |
| 3 | 2 | equal |
| 4 | 3, 1 | ¼, ½ |
| 6 | 6 | equal |
| 6 | 1 | equal |
| 2 | 1 | equal |
| 10 | 1 | equal |
| 2 | 3, 1 | ¾, ¼ |
| 12 | 3, 1 | ¾, ½ |
| 8 | 4, 4 | ¾, ½ |

It will be seen that there is no necessary correlation between the mitochondrial count and the relative size of the bud, or between that of the bud and mother cell. For example, a mother cell with six mitochondria may have only one mitochondrion, or may have six in its bud of equal size; or, a cell with ten mitochondria may have only one in its bud of equal size. These observations suggest that buds become detached at maturity or prematurely from the mother cell with inconstant, frequently low, even single mitochondrial complements, to yield the heterogeneous clones shown in Table 1.

A simple, directly observable explanation is thus provided for the origin from normal cells of occasional clones deficient in a cytoplasmic factor which is restorable on out-crossing to normal cells. It is reasonable to assume that distribution of mitochondria to the bud is random, and would not involve a preferential migration should the mother cell possess mitochondria of aberrant constitution. Indeed, instances of abnormal mitochondria have been reported in higher plants[2,3] and in yeast[4]. The present observations indicate that buds breaking away from the mother cell with only a single, 'mutant' mitochondrion, or without any 'normal' mitochondria, will be expected, as a consequence, to yield clones of 'vegetative mutants' breeding true to type such as the respiratory mutants encountered by Ephrussi. In view of the localization of a variety of enzymes in the mitochondria[5], this mechanism of the origin of vegetative mutants would explain irregularities in terminal genetical characters that are determined through the mediation of mitochondrial enzymes unless alternate pathways due directly to gene products become substituted for these deficiencies.

## Microbiological Decomposition of Litter

THE decomposition of tree litter has been the object of extensive chemical investigations; but the organisms involved in this process have attracted much less attention. Nevertheless, it appeared of interest to investigate which is the organism opening the attack on dead leaves falling from, or having fallen from, different trees in autumn.

Realizing the possibility that many kinds of organisms might be involved, we were prepared to use agar plates of different compositions; but we were surprised to find that the microflora of the leaves is much more uniform than might be anticipated. We proceeded as follows: from different trees we collected yellowed leaves, some on the point of falling, and others which had just fallen, using sterile tubes and sterile forceps. Without delay the leaves were shaken for several minutes in sterile tap water and a few loops were plated on malt agar. Using leaves of *Forsythia*, *Amelanchier*, oak, beech, apple and peach and many others, soon a very uniform growth appeared, consisting nearly exclusively of white colonies of a yeast-like organism, which proved to be *Pullularia* (*Dematium*) *pullulans* (de Bary et Low) Berkhout[1] (see photograph). A number of strains were isolated which proved to be varieties of this organism, differing somewhat in the rate of colour production (from brown-red to black) but identical in all other respects. In leaves picked up from the soil, secondary infection is not infrequent and often bacteria and moulds are numerous.

*Pullularia pullulans* from decaying litter

*Pullularia* attacks pectin strongly, and accordingly the above suspensions of leaves were also plated on pectin agar[2]. Nearly all the pectin-splitting colonies again were those of *Pullularia*, and only a few colonies of bacteria developed. When freshly collected leaves were kept between two sterile sheets of filter paper moistened with sterile water, the number of *Pullularia* increased considerably during the first two days, and many hundreds were found where only a few were present previously; other organisms were not found to increase in numbers. Hence it appears that not only does the overwhelming majority of the micropopulation of dead leaves of many trees consist of *Pullularia pullulans*, but also that this organism is the first one to develop under conditions similar to those in newly fallen litter. This suggests that the pectin of yellowed leaves is decomposed and thus the path is cleared for other organisms to penetrate into deeper layers; but further investigation is required.

Experiments with litter in a more advanced state of decomposition showed that *Pullularia* tends to disappear and is replaced by other organisms, among which bacteria and a few moulds prevail. Investigations on this secondary flora are in progress.

Meanwhile, it occurred to us that it might be worth while to investigate the microflora of leaves at the moment of budding, and so in early spring we made the same experiments with small green leaves, just after their appearance and also at a time when they were merely green buds. Again, among the pectin-splitting organisms *Pullularia* was frequent. In a quantitative experiment, 1 gm. of fresh leaves (*Amelanchier*) was shaken with 100 ml. of water for 5 min. and 0·1 ml. was plated. Four splitting colonies were found, three being *Pullularia*, or 3,000 per gm. of leaf. When the leaves were kept between moist filter paper for three days the number had increased to 287,000 per gm. Young leaves of beech were positive for *Pullularia*; oak and fir showed only fungi, some of which were pectin-splitting varieties. But again, after a few days between moist filter paper, the number of the pectin-splitting fungi had increased so abundantly that counting in 0·001 ml. was impossible. Hence decomposition of pectin by a small number of micro-organisms appears to be of very early occurrence in the decomposition of fallen litter.

## Effect of Added Primer on Lima Bean Phosphorylase

FORMATION of an amylose-type polysaccharide from glucose-1-phosphate by the action of phosphorylase does not take place unless a small amount of starch, glycogen or dextrin is added as the priming agent. The primer, which is sometimes called activator, is required presumably because the enzyme is unable to cause the condensation of glucose-1-phosphate, but acts only by transferring glucose units from glucose-1-phosphate to the non-reducing end of an already existing polysaccharide chain[1]. There have been reported, however, two exceptions which were claimed to require no added primer in this reaction; one is purified phosphorylase of lima bean, as reported by Green and Stumpf[2], and the other is that of sweet potato, as reported by Inoue and Onodera[3]. In both cases, according to these authors, the addition of different types of primers in various amounts had little or no effect on the initial velocity of this reaction catalysed by respective enzymes. In the case of purified lima bean phosphorylase, the possibility that the enzyme preparation might be contaminated with polysaccharide was excluded, since this preparation could not serve as a source of a polyhexose catalyst for purified potato enzyme.

In an earlier study[4] of the inhibition of phosphorylase by β-amylase, such as that found in crude extracts of sweet potato, barley or wheat, it was concluded that this inhibition might be due to destruction of added primer by the action of β-amylase to give limit dextrins, which had no priming effect on phosphorylase. Addition of appropriate amounts of mercuric compounds to these extracts, so as to inhibit selectively the β-amylase activity, enables phosphorylase in these extracts to utilize the added primer, and in this way phosphorylase activity can be detected in the presence of β-amylase[5]. It was found later[6] that purified potato phosphorylase, although still contaminated with a small amount of β-amylase, actually required the added primer in the synthesis of starch from glucose-1-phosphate.

Lima bean phosphorylase was purified by the method of Green and Stumpf[2]. The purest preparation thus far obtained after eight fractionations with ammonium sulphate with frequent dialyses had a specific activity (enzyme activity in units (37°)/mgm. protein) of 0·62, thus indicating that this preparation was much inferior in purity to purified potato enzyme, the specific activity of which was usually 2·5–3·0 after four fractionations. No further purification could be attained by the use of various procedures.

Nevertheless, this preparation required an added primer in the synthesis of starch from glucose-1-phosphate, as can be seen in a typical experiment represented in Fig. 1. From this and other similar experiments, the enzyme–primer dissociation constant was calculated by the graphical method of Lineweaver and Burk[7]. The value of $Ks$ thus obtained was 1·05 mgm. Lintner's soluble starch per 3·5 ml., or approximately 30 mgm. soluble starch per 100 ml. This is comparable with the values previously obtained for potato phosphorylase (41 mgm. Lintner's soluble starch per 100 ml.[8]; 97 mgm. Zulkowski's soluble starch per 100 ml.[9]) and for crystalline muscle phosphorylase[10] (20 mgm. glycogen per 100 ml.). The iodine colour reaction of the products of this reaction, using a small amount of dextrin (Merck; iodine colour, red) as the source of primer, changed from red-purple via purple to deep blue, indicating the formation of an amylose-type polysaccharide.

The purest enzyme preparation used in the above experiment still contained a trace of primer polysaccharide, as can be seen in a typical experiment represented in Fig. 2. Treatment of the boiled lima bean enzyme with purified sweet potato β-amylase was effective in removing the contaminating primer, which is a further proof of its polysaccharide nature. The exact amount contained in the purified lima bean preparation was not determined, but a simple calculation shows that the amount is far less than 2 mgm. soluble starch per ml. enzyme preparation, which is enough to give a half-maximal activity to the potato enzyme in the experiment of Fig. 2. This amount of polysaccharide, which corresponds to 0·05 mgm. soluble starch contaminated in the lima bean enzyme used in the experiment of Fig. 1, will give an error of approximately 5 per cent in the determination of the $Ks$ value; an error of this order is permissible in experiments of this nature.

Although I cannot account for the results obtained by Green and Stumpf, it can now be said that, without exception, phosphorylase requires an already existing polysaccharide primer in the synthesis of starch from glucose-1-phosphate.

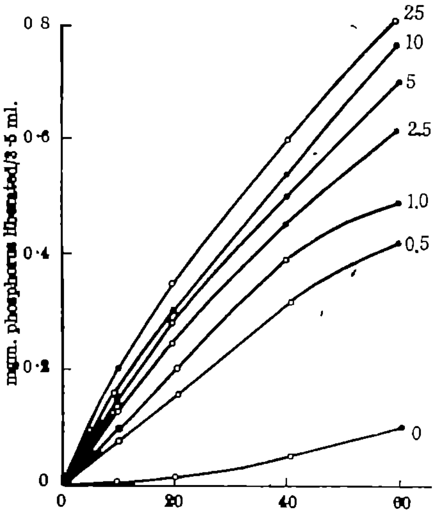

Fig. 1

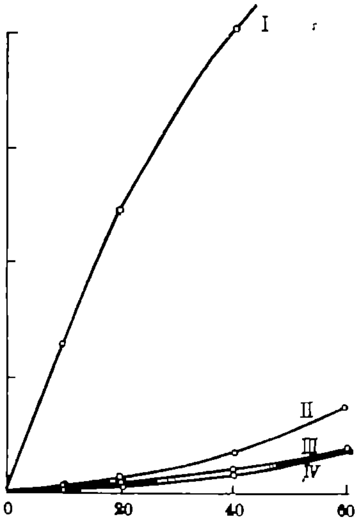

Fig. 2

Fig. 1. Effect of added primer on purified lima bean phosphorylase in the synthesis of starch from glucose-1-phosphate. The reaction mixture contained 1 ml. 0·5 *M* acetate buffer ($p$H 6·0), 0·5 ml. purified lima bean phosphorylase (prep. *LB.B8*; 1/20 diluted), 1 ml. 0·1 *M* glucose-1-phosphate, and various amounts of Lintner's soluble starch as indicated on the curves. Total volume, 3·5 ml. Incubation temperature, 37 ± 0·1°. At intervals, samples were withdrawn from the digests, deproteinized with 5 per cent perchloric acid, and tested for inorganic phosphorus

Fig. 2. Effect of primer polysaccharide in purified lima bean phosphorylase. The standard digest (curve IV) contained 1 ml. 0·5 *M* acetate buffer ($p$H 6·0), purified potato phosphorylase, and 1 ml. 0·1 *M* glucose-1-phosphate. Other digests contained in addition: curve I, 25 mgm. Lintner's soluble starch, curve II, 0·5 ml boiled lima bean enzyme (prep. *LB.B8*); curve III, 0·5 ml. boiled lima bean enzyme, treated with purified sweet potato β-amylase, and heat-inactivated. Total volume of each digest: 3·5 ml. Incubation temperature: 37 ± 0·1°. At intervals samples were withdrawn, deproteinized with 5 per cent perchloric acid, and tested for inorganic phosphorus

The lima bean used in this study was a commercial product (Baby lima beans from Chester B. Brown Co., Morrill, Nebr., U.S.A.), made available by the courtesy of Messrs. S. Wada and N. Yamada, to whom I wish to express my thanks.

# Experimental Dissociation of Cells from Chick Embryos

DURING the development of an embryo, a very important part is probably played by the forces of attachment between cells. Weiss[1] in particular has emphasized the importance of interactions between cell surfaces in the processes leading to tissue differentiation. Holtfreter[2,3] has shown that the cells of the young amphibian embryo can be dissociated experimentally by alkali-treatment, and Mookerjee *et al.*[4] has made a comparative study of the firmness of cell-attachment both in different species of Urodele and during the course of differentiation of one particular organ, the notochord. A similar type of cell-dissociation has now been shown to occur in the chick embryo.

Whole embryos, or parts of them, at the primitive streak stage, are placed in chick Ringer solution the $p$H of which had been brought to 9–9·2. Within a few minutes the cells fall apart either singly or in small groups. The cells are at first rounded, but may later become elongated or flattened, with irregular outlines. An intake of water clearly occurs, and an ectoplasmic layer may be lifted off from the endoplasmic interior. The ectoplasm may assume the form of a lobular pseudopodium, which can appear at any point on the cell surface. With increasing imbibition of water the ectoplasm may be lifted away from the endoplasm over the whole surface of the cell. Churning movements are visible within the endoplasm. Over-exposure to alkaline media renders the cell surface so permeable that large visible particles may leak out through the membrane, which eventually may take on a crenated appearance shortly before the death and complete disintegration of the cell. Except in the final stages, these cell changes are quickly reversible by alteration of the $p$H to the acid side. The general picture is thus extremely similar to that seen in the tissues of early amphibian embryos.

After the experiments reported here were concluded, Moscona and Moscona[5] have published observations on the dissociation of tissues of later stages of the chick embryo.

The work described here was carried out while I held an I.C.I. Research Fellowship of the National Institute of Sciences, India. Thanks are due to Dr. Subodh Mittra, director of the Chittaranjan Cancer Hospital, for the provision of laboratory facilities.

## Rapid Specific Preventive Action of Tetanus Toxoid

KRECH[1] has found that mice infected with tetanus spores could be saved by toxoid alone, an antitoxin not being used, whereas the control animals died. He also gave toxoid in two doses 24 and 48 hr. before a lethal dose of toxin. The eight mice injected with toxoid survived while the two control animals died on the sixth and ninth day respectively. He concluded that these effects were due to the rapid formation of antibodies. Lemétayer[2], also using toxoid, was able to produce a retardation of the onset of the signs of tetanus if he gave it one day before the toxin.

Raynaud *et al.*[3], using larger doses of toxoid, given one day before, were able to prevent all signs and lethal effect of 1 minimum lethal dose (m.l.d.) of toxin. These results were obtained by subcutaneous injections into the hind limbs, and there was the possibility that these effects could be either local or non-specific. Again, the effect may only have been produced if the toxin and toxoid were made from a filtrate produced by one strain of organism.

In the experiment described below, an attempt was made to overcome these objections. The toxoid was given intravenously, a toxoid from another laboratory was used, and an extra control group of mice was given diphtheria toxoid.

Table 1. MICE WERE GIVEN 1 M.L.D. OF TETANUS TOXIN SUBCUTANEOUSLY. SOME HAD RECEIVED VARIOUS TOXOIDS INTRAVENOUSLY 24 HR. EARLIER

| Type and dose of toxoid | No. of mice used | No. of animals dying of tetanus in less than 6 days | Remarks |
|---|---|---|---|
| Tetanus (Copenhagen) 500 Lf | 6 | 0 | None died or showed local tetanus* |
| Diphtheria (Copenhagen) | 6 | 6 | All showed local tetanus on second day after toxin |
| Tetanus (Pasteur) 700 Lf | 6 | 0 | None died or showed local tetanus* |
| Nil | 6 | 6 | All showed local tetanus on second day after toxin |

* Observed for 20 days.

The results in Table 1 show that tetanus toxoid given intravenously completely prevents the onset of local tetanus and death from 1 m.l.d. of toxin given subcutaneously 24 hr. later. The amount of toxoid used was very large when compared with the amount of toxin, for as 1 Lf of toxin is approximately equivalent to 10,000 mouse m.l.d. of toxin, the toxoid/toxin ratio in these experiments is approximately $5 \times 10^6$ to $7 \times 10^6$.

In another experiment it was found that 200 Lf of toxoid gave complete protection against 1 m.l.d. of toxin but not against 4 m.l.d. Using this smaller dose of toxoid, 1 m.l.d. of toxin was given to groups of mice at increasing intervals after the toxoid (see Table 2). These results show that the protection lasts only a short time, for even when the toxin was given two days after the toxoid few animals survived. When the interval was six days no protection was found.

Krech's suggestion that this phenomenon is due to rapid formation of antibody appears to be untrue, as no antibodies have been detected during the first days after administration of toxoid (unpublished work). The most probable explanation of the action of toxoid would appear to be either a prior blocking of the hypothetical receptor substance in the central nervous system, similar to an interference phenomenon, or a competitive inhibition of the action of the toxin.

Table 2. TETANUS TOXOID (200 LF) WAS INJECTED INTRAVENOUSLY INTO MICE AND 1 M.L.D. OF TOXIN WAS GIVEN SUBCUTANEOUSLY 1–6 DAYS LATER

| Intervals between giving toxoid and toxin (days) | No. of animals in each group | Number of animals surviving at various times after the injection of toxin (days) | | | |
|---|---|---|---|---|---|
| | | 4th | 8th | 12th | 16th |
| 1 | 6 | 6 | 6 | 6 | 6 |
| 2 | 6 | 6 | 4 | 2 | 1 |
| 3 | 6 | 6 | 4 | 2 | 2 |
| 4 | 6 | 6 | 3 | 2 | 1 |
| 5 | 6 | 4 | 3 | 2 | 1 |
| 6 | 6 | 3 | 2 | 1 | 0 |

The phenomenon is being investigated to determine which of the two probable explanations is correct, and also to find out if other toxoids can protect animals from their analogous toxins.

## Isotope Curves in Red Blood Cell Studies

WHEN iron-55 or a carbon-14—or nitrogen-15—labelled substrate is fed to an individual, a portion of the isotope is incorporated in red cell hæmoglobin[1-4]. Curves of subsequent changes in the amount of isotopic excess can be explained and used for calculating the survival curve of red cells, as well as their average time of utilizing the incorporated substance.

A schematic curve is shown in Fig. 1 over a time scale marked at about 30-day intervals. The tagging during the first month reflects mitosis and maturation in the bone marrow, while the plateau of the second month shows completion of the isotopic uptake. Mollison[5] and Rimington[6] gave qualitative descriptions of the reutilization represented by the singly hatched area of Fig. 1.

To get the average cell life $L$, the reutilization fraction $r$, and the average material utilization time $T$, consider Fig. 1 with total hatched area $A$, cross-hatched area $A'$, and $B$ and $H$ as shown. A convenient method of determining these areas consists of plotting them on paper of known and uniform mass per unit area, cutting out and weighing the outlined areas, and calculating them from their masses. Then $T = A/H \doteqdot A'/(H-B)$ and $L \doteqdot A'/H$ and

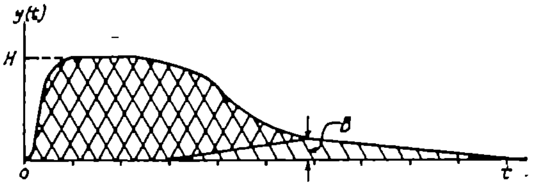

Fig. 1. Schematic curve of isotopic tagging of red-cell hæm

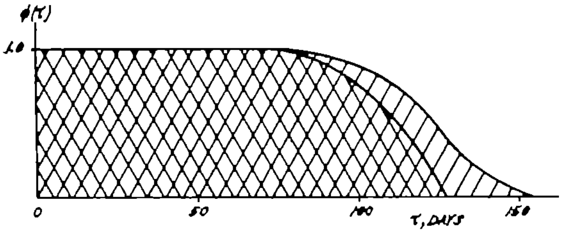

**Fig. 2.** Approximate survival curve of animal red cells (ref. 1) including designation of the wearing fraction

$r = l - L/T \doteqdot B/H$. In normal cases[1-3,7], $L$ is 100–130 days, $T$ is between 125 and 145 days for nitrogen and carbon and between 390 and 580 days for iron, while $r$ is 0·1–0·25 for nitrogen and carbon and 0·65–0·8 for iron.

To determine the fraction of red cells surviving to each age of $\tau$ days, or $\varphi = \varphi(\tau)$, let $y_0 = y_0(t)$ represent the height of the cross-hatched area above time $t$. With this correction for reutilization, apply equation (16) of ref. 1 in the form

$$\varphi(\tau) = y_0(\tau+\tau_0)/H - \frac{dy_0(\tau+\tau_0)}{d\tau}\Big/ bH,$$

which allows a correction of a couple of days, $\tau_0$, for averaging out any prolongation of the feeding time and for deducting the initial lag of about a day in the release of tagged cells—the $b$ of this equation is the fraction (empirical) of previously unreleased tagging that is released each day. To obtain further detail in the description of red cell survival, consider the two sequential stages in the lives of circulating red cells[8]. These are (i) a period of wearing and (ii) a subsequent random breakdown of worn cells. Evidence of these two stages is found in Ashby curves discussed in an earlier communication[8]. If $k$ is the rate of random breakdown, or $\max_{\tau}\left(\frac{d\varphi(\tau)}{d\tau}\Big/\varphi(\tau)\right)$, and if $\varphi_1(\tau)$ is the fraction of cells still undergoing wearing at time $\tau$, then $\varphi_1 = \varphi_1(\tau) = \varphi(\tau) - \frac{d\varphi(\tau)}{d\tau}\Big/k$. The result of applying the equations for $\varphi$ and $\varphi_1$ to a normal case[1] is shown in Fig. 2, in which $\varphi$ covers the total hatched area and $\varphi_1$ covers the cross-hatched area. Because of the reutilization correction, these results are an improvement on those of Shemin and Rittenberg[1], while the addition of $\varphi_1$ is a motivated extension.

The $\varphi$ used here is the same as that of Callender, Powell and Witts[9], but its determination is more direct in the isotope studies than in the Ashby studies. The case of Fig. 2 shows a wider spread in the times of declining $\varphi$ than do their Ashby cases.

The proper value of $L$ is given by $L = \int_0^\infty \varphi(\tau)d\tau$, and this agrees with the above expressions for $L$. These estimates of $L$ are more accurate than the earlier assumption of symmetry of $\frac{d\varphi(\tau)}{d\tau}$ about $\tau = L$[1,7]—although the latter procedure tends to compensate for the lack of the reutilization correction.

Diseases like sickle cell anaemia[7], which involve relatively short values of $L$, are still incompletely analysed.

This investigation was sponsored by the Veterans Administration and is published with approval of the Chief Medical Director. ## Red-Cell Survival and Ashby Curves

Callender, Powell and Witts[1] gave an expression for the determination of the fraction of red cells surviving to age $\tau$, or $\varphi = \varphi(\tau)$, from the Ashby curve[2] of $Y = Y(t)$, which is the number of transfused red cells surviving in the recipient at time $t$. Their equation is, with average red-cell life $L = \int_0^\infty \varphi(\tau)d\tau$, $\varphi(\tau) = -L\frac{dY(\tau)}{d\tau}\Big/Y_0$, where $Y_0$ is the number of red cells transfused (these are assumed to be a representative steady-state population). The importance of this result has not previously been fully realized.

The application of the above expression for $\varphi$ should be extended considerably when it has been supplemented with a good method of determining the scale factor $L/Y_0$. The determination of $L$ in this factor appears to require previous knowledge of $\varphi$.

However, $\varphi(0) = 1{\cdot}0$, so that $L/Y_0 = -1\Big/\frac{dY(0)}{dt}$, and thus the difficulty can be solved by getting a good value for the initial Ashby slope, $dY(0)/dt$, at least whenever the curve is not complicated by donor-recipient differences. In the latter cases $dY(0)/dt$ can be determined by extrapolation from later times on a preliminary plot. Ashby curves showing rapid cell destruction are essentially exponential, whereas those showing the slower normal destruction are roughly linear, so the preliminary plots of $dY(t)/dt$ should be made on semilog and linear paper, respectively, for those two types of $Y$ curves. With this judiciously chosen (possibly extrapolated) value of $dY(0)/dt$, the final result is

$$\varphi(\tau) = -\frac{dY(\tau)}{d\tau}\Big/\frac{dY(0)}{d\tau}.$$

According to the motivated interpretation of Ashby curves[3], the circulating red cells undergo two successive stages in their life-history: (i) a period of wearing the duration of which depends on the donor, except in recipients having acquired anæmia, and (ii) a period of subjection to a first-order random breakdown at a rate that depends on the surrounding environment and which can therefore differ between donor and recipient. This interpretation agrees with Callender, Powell and Witts's result, and it further shows that if $\int_0^\infty \varphi(\tau)d\tau$ is calculated from the $\varphi$ observed in the recipient, it will give the $L$ for the donor (except with recipients having acquired anæmia) because of a compensation between the effects of donor-recipient differences at the two ends of the observed curve.

Fig. 1 illustrates the result of applying this treatment to a curve of normal cells in a recipient with idiopathic hypochromic anæmia[4]. For this case $L$ is about 85 days. It shows a greater spread in the times of declining $\varphi$ than do the curves of Callender, Powell and Witts[1]. In that regard it resembles more closely the normal survival curve determined by the more direct and therefore more accurate method of isotopic tagging[5,6].

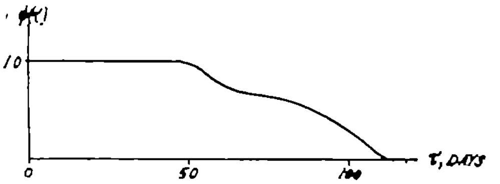

Fig. 1. Approximate survival curve of normal cells in a recipient with idiopathic hypochromic anæmia (ref. 4)

However, the results of isotopic tagging in cases like sickle cell anæmia, which involve short values of $L$, are not yet fully explained[7]. On the other hand, Fig. 2 shows $\varphi$ for sickle cell anæmia as calculated by the above method from an Ashby curve of Callender, Nickel, Moore and Powell[8]. For this case $L$ is about six or seven days. The $\varphi$ curve is evidence of wide gradation between a large fraction of cells that die rapidly and a much smaller fraction with much longer survival times. In particular, the original Ashby curve is represented approximately by the equation $Y(t) = 0{\cdot}35\,(\exp - 0{\cdot}25t) + 0{\cdot}29\,(\exp - 0{\cdot}035t)$, so that empirically about $0{\cdot}35 \times 0{\cdot}25/(0{\cdot}35 \times 0{\cdot}25 + 0{\cdot}29 \times 0{\cdot}035)$, or 0·9 of the cells may have an average life of about 1/0·25 or four days, while the rest may have an average life of about 1/0·035 or thirty days. This result should aid the eventual elucidation of such cases.

This investigation was sponsored by the Veterans Administration and is published with approval of the Chief Medical Director. The statements and conclusions published by the authors are the result of their own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

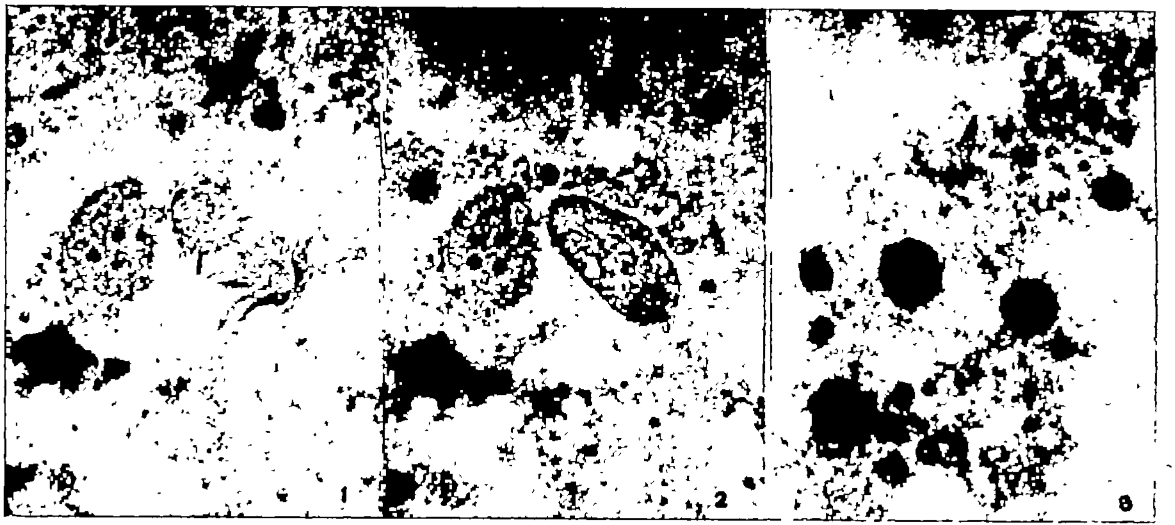
## Dividing Nuclei in Coconut Milk

Cutter, Dubé and Wilson[1] have published some interesting information regarding the growth and development of the coconut fruit. Apart from physiological studies on the growth and development of the endosperm tissue, they have detected the presence of free nuclei suspended in the milk, and by slowly centrifuging the milk they have successfully isolated such nuclei in the living state. The present observations have resulted from an attempt to follow up that work to see whether the fruit with its exposed nuclei can be used as a living receptacle for testing the direct effect of antibiotics and other substances on chromosomes. Hitherto, such studies have been confined to onion root tips, which can be made to grow in water.

Coconuts of graded size were collected from the experimental station of the Bose Institute and stored in the cold room (25° ± 2° C.) for a week. Fruit were cut open every day to observe (1) in which stage the free nuclei appeared, (2) whether growth of tissue took place by somatic divisions, and (3) whether division could continue in fruit after they had been picked from the tree. The solid or semi-solid endosperm and drops of the liquid milk were fixed in acetic alcohol and aceto-carmine, or Feulgen squashes were afterwards prepared. As observed by Cutter *et al.*, the tissue is at first a syncitium but later becomes walled. It will be seen from the accompanying photographs that the nuclei are of different sizes, in the present instance varying in diameter from 16·6 μ to 72·2 μ. The meristem of the endosperm creeps along the inner face of the endocarp, starting from the micropylar end towards the other side and covering the walls completely as it progresses. The endosperm grows also in thickness; but due to the large size of the embryo sac, the inner cavity is never completely filled up, and there is a little water containing free nuclei right up to the end of development in the mature fruit. This type of embryo sac is unknown in other families and cannot be classified under any of the types of Maheshwari[2] or Johansen[3].

A drop of milk mounted without fixation or staining may be seen to carry many of these free nuclei, some of which may even be in the dividing state, with large spindle, chromosomes and perhaps an



Photographs from a drop of water mounted straight from the fruit. (1) Two free nuclei, one in resting condition and the other at late telophase. There are fragments of cytoplasm and some bacteria in the field. All are suspended in the water or 'milk'. (2) The same two nuclei photographed 10 min. later. The one at telophase has reverted to one nucleus, conditions being unfavourable for the progress of division. (3) Nuclei of various sizes embedded in a floating mass of cytoplasm. Nuclei have taken up the vital dye, acridine orange. × 3,500

adhering film of cytoplasm. Chromosomes may be visible under high power (× 400) only. Regular somatic division figures, however, have been seen in free nuclei adhering to the tissue, in those inside the syncitium and in those in the walled tissue. Chromosome counts have been obtained from stained material. They vary from $32(2n)$, $48(3n)$ to $160(10n)$. The meristematic syncitium of the fruit may show abundant division figures after being stored in the cold room for as long a period as eight days, but not if kept in the refrigerator for even six hours. At the latter temperature (5° C.), nuclei pass into the 'resting' stage.

Cutter, Dubé and Wilson were not able to detect any division figures in the endosperm and concluded that the tissue perhaps divides 'amitotically'. Present observations do not support this view. These authors also mention that free nuclei are found in the milk before endosperm development begins, and they think that development of the endosperm is initiated by deposition of these nuclei on the walls of the embryo sac. My observations, however, show that the free nuclei do not appear in the water until a little of the endosperm, if only the barest film, has begun to form. It appears more likely that these free nuclei become detached from the loose jelly of the syncitium and become suspended in the water. Otherwise, their origin is difficult to visualize.

Further cytological and experimental work is being carried out with this very promising material, which yields such large numbers of chromosomes almost directly exposed in the water, unbounded by cytoplasm or cell wall. Preliminary observations have been made on the fruit of the betel nut (*Areca catechu*, Linn.), which resembles the coconut fruit in appearance and development, starting with the large embryo sac cavity filled with water, although about a twentieth the size of the coconut fruit. In this case the little cavity, containing not more than 2 c.c. of water, finally becomes completely filled by growth of the endosperm, and the edible nut is actually formed of the hardened endosperm. In a drop of the water mounted under the microscope, the same type of free nuclei can be seen, some of them dividing, with the large spindle figure and chromosomes discernible under high power. The chromosomes are smaller than those of the coconut.

Coconuts and allied fruits are therefore not only good sources for obtaining measurable quantities of free nuclei, as found by Cutter, Dubé and Wilson, but may also be observed for chromosomes as well. They are easily accessible, yield a great deal of material and may be stored for days without deterioration.

Thanks are due to Dr. D. M. Bose, director of the Bose Institute, for his encouragement in the work, and to Sri K. L. Chaudhuri of the Institute for the photomicrographs.

## Occurrence of *Verticillium* in Potato Tubers in India

*Verticillium* wilt of vascular plants has been reported from various countries. In India it has been recorded by Patel, Qureshi and Bhide on egg plants (*Solanum melongena*)[1]. Though very common in potatoes, it has not been noticed in India until now.

In September 1952, while collecting potato tubers from different cultivated crops in the Bhowali–Naini Tal area, we came across several diseased tubers, one of which yielded species of *Fusarium* and *Verticillium*. This species of *Verticillium* closely resembles *V. albo-atrum* R. and B.

On potato dextrose agar its characters are as follows: conidia ellipsoidal, unicellular 4–8 × 1·5–3 μ; primary whorl of branches, 2–7 in number and 32–48 μ apart, bearing secondary branches; conidiophores, 120–230 μ in length. The terminal branch of the conidiophore is 16–24 μ in length. Conidia are sometimes collected in heads on the sterigmata tips.

This is the first report of *Verticillium* attacking potatoes in India. Presumably it causes considerable damage to potato crops here. Further work on the morphology, cultural characters and pathogenicity is being studied in detail.

## A Cinematographic Technique, using Ultra-violet Illumination, for Amphibian Blood Circulation

EVER since Marey[1] used cinematographic techniques in 1892 for recording the circulation in a tortoise's heart, many biologists have found the ciné camera a useful instrument for the registration of cardiac movements. Many details of amphibian circulation are, however, not yet fully agreed upon, and in a series of recent papers, Foxon[2] revived the controversy about the selective or non-selective distribution of the oxygenated and de-oxygenated blood to the arterial arches in the heart of the frog, *Rana temporaria*. While Foxon claimed to have established a non-selective distribution by means of direct X-ray cinematography, the present work shows that, in *Hyla cærulea* at least, the blood is sometimes distributed in the manner postulated by the classical theory of Brucke and Sabatier; that is, the streams of deoxygenated and oxygenated blood are kept distinct and distributed selectively to the arterial arches.

Direct X-ray cinematography has always suffered from the necessity of moving comparatively large masses of sensitive material and of using lead-shutters, and has thereby restricted the frequency and total duration of exposure. Foxon was able to obtain only fifteen pictures for each experiment at 3 frames per sec. recording two to three cardiac cycles during the 5 sec. of his total exposure. The present technique consisted in the direct recording, at 16 frames per sec., of the exposed amphibian heart on colour film, using a source of illumination rich in the ultra-violet region of the spectrum and showing up blood circulation by the injection of fluorescein.

After opening the abdominal cavity of an anæsthetized frog, *Hyla cærulea*, about 1 c.c. of frog-Ringer solution containing 0·005 gm. of fluorescein per ml. was injected slowly into either the anterior abdominal or the left jugular vein. The source of illumination was a 500-W. D.C. high-pressure mercury vapour lamp, and in order to eliminate most of the visible light, a Corning filter, No. 5113, having a transmission of 45 per cent at 4050 A., was interposed. Similarly, to absorb any reflected ultra-violet radiation, a Corning filter, No. 3421, was placed between the amphibian heart and the lens of the ciné camera. A Ciné Kodak Special I, with a 63-mm. lens, *f* 2·7, and 50-mm. extension tube, was used and records of considerable contrast resulted. Due to the heavy absorption of the filter No. 5113, the colour balance of the Kodachrome, type *A*, was materially upset and produced bright yellow blood-vessels on an under-exposed blue background, a highly desirable and not unpleasing effect. Evaluation of the films was carried out by preliminary loop-projection and later by detailed frame analysis.

Apart from immediate visual inspections on thirty other frogs by one of us (J. R. S.), a total of eight cinematographic records were made with the above technique, six of which showed a non-selective distribution of the blood and two a highly selective distribution in which the dyed venous blood passing out from the ventricle was sent to the pulmo-cutaneous and systemic arches but not to the carotid arch. In one of these two films the dye is seen clearly entering the pulmo-cutaneous arch before it appears in the systemic arch. This type of distribution conforms so closely to that postulated by the classical theory that we consider Foxon's categorical statement: "the classical hypothesis is, quite frankly, wrong" to be untenable as a general statement, and that in certain circumstances the blood is distributed as Brucke and Sabatier have postulated.

Further work is proceeding in order to determine what the exact circumstances are which bring about this selective distribution; but in the meantime it is hoped that the cinematographic technique, described above, might prove useful to other workers in this and other biological investigations.

[1] Marey, E. J., "Le mouvement du cœur, étudié par la chronophotographie", Monit. photogr. 1892, p. 162 (Le Mouvement, Masson, Paris, 1894; Heinemann, London, 1895).

[2] Foxon, G. E. H., *Proc. Zool. Soc. London*, **121**, 529 (1951).

---

THE method described by Simons and Michaelis for the study of the amphibian circulation seems to promise to be useful, and full results should be most interesting.

Before, however, I can begin comparing the results of Simons and Michaelis on *Hyla cærulea* with my own and those of other workers who have used *Rana temporaria* and *Bufo bufo*, it seems desirable that we should agree as to what precisely the term 'classical hypothesis' denotes. My own view has been that it is a hypothesis concerning the mode of action of the anuran heart which accounts for a selective distribution of the blood from the two auricles (I do not call it 'oxygenated' and 'deoxygenated' blood, for in *Rana* there is no evidence that the degree of oxygenation of the blood in the two auricles is constantly different). The real basis of the 'classical hypothesis' is differences in pressure in various vessels, which cause the blood leaving the ventricle during different phases of systole to be directed in various ways, causing differences in the time of movement of the blood in the principal arteries. Also, blood is supposed to flow at one time up one side of the spiral valve of the conus and another time up the other side. Vandervael[1] stated that these time differences were not to be seen in frogs in which the heart and arteries were viewed by trans-illumination. I confirmed[2] his results using similar methods; thus the evidence that the heart of the frog *Rana temporaria* does not function in the manner of the classical hypothesis has nothing to do with injection studies of any kind. The classical hypothesis of the mode of action of the heart is, I believe, not correct. This, however, as I[2] pointed out, does not preclude a selective mechanism of distribution of blood brought about by the anatomical arrangements of the heart. Vandervael[1], by the injection of indian ink in *Rana*, concluded that mixing of the blood from the two auricles was complete, and I[2] have said that the mixing of the indian ink was considerable; Savolin[3], working on *Bufo bufo*, also found that mixing was considerable, although there might be some selection whereby the carotid arteries received slightly less of the blood from the right auricle than did the systemic and pulmo-cutaneous arches.

The radiographic studies referred to by Simons and Michaelis have been undertaken mainly as an illustration of the results achieved by indian ink injections. It was hoped that perhaps the densities of the shadows might have allowed of some evaluation of the degree of mixing taking place, but this has not been possible. I have never claimed to have demonstrated complete mixing; however, I believe mixing to be considerable.

I believe that in Anura we see a group of animals which have become greatly modified in many respects, not least in regard to skin respiration. In correlation with skin respiration we see also a highly modified heart, for I think it likely that in early Amphibia the division of the heart into two sides was more complete than in modern members of the group. If this is so, we are seeing a loss of division in the heart, and, in fact, it is well known that more aquatic amphibians show great reduction of the spiral valve and fenestration of the inter-auricular septum (see Noble[4]). It is therefore to be expected that certain Anura have a more selective circulation than others, and it is probable that *Hyla cœrulea* is one of these. What is new is the suggestion that this selective circulation can be switched on or off according to circumstances. I shall await further reports with interest, particularly those of the actual mechanism by which selection is accomplished.

## Pharmacology of the Alkaloids of *Aspidosperma oblongum* A.DC.

A PRELIMINARY pharmacological investigation of the total alkaloids of *Aspidosperma oblongum* A.DC. obtained by classical methods has been carried out. A 6 per cent solution of the hydrochlorides in an appropriate isotonic saline at *p*H 6·8 was used.

The solution caused relaxation and loss of tone when applied to the isolated ileum of the rabbit and rat. Peristalsis was inhibited in proportion to the dose given. The characteristic actions of acetylcholine and barium chloride were antagonized. The antagonism to acetyl-choline bore a linear relationship to the dose given. The characteristic effects of histamine and acetyl-choline on the guinea pig ileum were antagonized, the antagonism bearing a linear relationship to the dose given.

The normal movements of the isolated uterus of the rabbit, guinea pig and rat were inhibited and the actions of acetyl-choline and barium chloride strongly antagonized.

Antagonism to the action of adrenaline on smooth muscle was demonstrated on the isolated rabbit uterus.

In the frog rectus abdominis muscle preparation, a linear relationship between dose of the alkaloids and extent of inhibition of the action of acetylcholine was demonstrated. About one-tenth of the activity of curarine chloride was shown in this respect.

In the frog gastrocnemius sciatic nerve preparation, a curare-like neuro-muscular blocking action reversible by physostigmine was demonstrated.

When tested by Sollmann's frog plexus anæsthesia method[1] as modified by Bulbring and Wajda[2], a graded local anæsthetic action was shown.

In the isolated and *in situ* frog-heart preparations the rate and amplitude of the contractions were reduced by a small dose (0·06 mgm.). A larger dose (0·6 mgm.) caused irreversible stoppage. Prior atropinization did not modify these effects. Electrical stimulation of the vagus in the latter preparation did not produce its characteristic effects.

In Langendorff heart preparations of the cat, rabbit, guinea pig and rat, the alkaloids caused a reduction in rate and amplitude followed by a well-marked auriculo-ventricular block, unmodified by previous atropinization. The block was reversible.

In the rabbit and the rat electrocardiogram, doses which caused marked slowing of the heart were seen considerably to reduce the amplitude of the *P* wave, to invert the *QRS* wave and to prolong and increase the amplitude of the *T* wave. The *PT* interval was almost doubled.

Intravenous administration of small doses to nembutal-anæsthetized rabbits and cats lowered the blood pressure and slowed the heart.

Doses of 6–30 mgm. were injected into the ventral lymph sacs of frogs. Complete paralysis was exhibited within a few minutes. The higher dose caused death within thirty minutes; at lower dose-levels there was occasional recovery.

In mice and rats parenteral administration of sublethal doses of the alkaloids caused the animals to become quiet and their movements sluggish. The eyelids were closed and there was an appearance of drowsiness. The limbs were extended, the heart slow and irregular. Complete recovery took about two hours. Lethal doses caused slowing and irregularity of the heart followed by violent clonic convulsions. Convulsive episodes alternated with periods of exhaustion. Death was due to heart failure.

Our investigations point to the presence of a potent cardioactive substance which antagonizes acetyl-choline or is associated with substances having this property. Studies on the chemistry and pharmacology of this substance are in progress.

We thank Mr. D. B. Fanshaw, conservator of forests, British Guiana, for the barks; Major J. Buchanan, of Messrs. A. C. Cossor, Ltd., for technical advice with the Cossor 1314, E.C.G., and Mr. G. E. Trease, director of pharmaceutical studies in the University of Nottingham, for permission to publish this communication.

## Monday, May 4

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. P. de Béthune. "Appalachian Relief".

British Society for the History of Science (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Annual General Meeting, with Presidential Address.

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. E. P. Johnson: "Gas Turbines in Retrospect and Prospect".

## Tuesday, May 5

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. D. M. MacKinnon: "On the Notion of a Philosophy of History".*

University of London (in the Chemistry Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. R. W. G. Wyckoff, For.Mem.R.S.: "The Structure of some Biologically Important Solids".*

## Wednesday, May 6

University of London (at the School of Pharmacy, 17 Bloomsbury Square, London, W.C.1), at 5.30 p.m.—Dr. W. O. James, F.R.S. "The Formation of Alkaloids in Plants".* (Further Lecture on May 7.)

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. G. I. Hitchcox: "Recent Advances in the Application of Electronics to Chemical Instrumentation".

Society of Public Analysts and Other Analytical Chemists (joint meeting of the Microchemistry Group and the Scottish Section, in the Chemistry Department, The University, Glasgow), at 7.15 p.m.—Scientific Papers.

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Nature and Constitution of Viruses" (Chairman: Dr. A. S. McFarlane; Speakers: Dr. P. R. Lépine, Dr. R. W. G. Wyckoff, For.Mem.R.S., Mr. F. C. Bawden, F.R.S.).

## Thursday, May 7

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. N. F. Mott, F.R.S.: "Dislocations, Plastic Flow and Creep in Metals" (Bakerian Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. John Gilmour, Dr. J. Ramsbottom, Dr. T. A. Sprague and Mr. W. T. Stearn: Papers to commemorate the Bicentenary of the publication of the "Species Plantarum".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. L. J. Davies: "Research in the Electrical Manufacturing Industry".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

## Friday, May 8

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. A. J. S. Pippard: "The Civil Engineer in the Laboratory".

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer in Mathematics—The Registrar, The University, Reading (May 9).

Colville Fellowship tenable in the Department of Chemistry—The Professor of Chemistry, Royal Technical College, George Street, Glasgow (May 9).

Engineer to control, under Assistant Director, large engineering workshop making wide range experimental apparatus at the Ministry of Supply, Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.193/53A (May 9).

Lecturer (Grade B) in the Department of Mathematics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (May 9).

Plant Physiologist in the Botany Department—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Street, Edinburgh (May 9).

Assistant Biochemist (Basic Grade) (with a university degree or equivalent)—The Group Pathologist, Group Pathological Laboratory, Lakin Road, Warwick (May 11).

Reader in Civil Engineering at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 11).

Senior Lecturer or Lecturer in Civil Engineering, a Senior Lecturer or Lecturer in Electrical Engineering, two Senior Lecturers or Lecturers in Mathematics, two Senior Lecturers or Lecturers in Chemistry, a Senior Lecturer or Lecturer in Physics, and a Senior Lecturer or Lecturer in Zoology, at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Council on Colonial Colleges, 15 Victoria Street, London, S.W.1 (May 11).

Assistant Lecturer in Chemistry—The Principal, Royal Holloway College, Englefield Green, Surrey (May 15).

Leverhulme Studentships in Chemical Engineering—The Registrar, University College, Gower Street, London, W.C.1 (May 15)

Senior Lecturer in Veterinary Medicine—The Secretary of University Court, The University, Glasgow (May 15).

Electrical Engineers and Physicists (Scientific Officer grade—Ref. A.92/53A; Experimental Officer or Assistant Experimental Officer grade—Ref. A.337/52A) for interesting research or development work on radar equipment for Forces, in the Ministry of Supply at Malvern—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (May 16).

Esso Research Studentship in Chemistry—The Professor of Chemistry, The University, Southampton (May 16).

Lecturer in Zoology (with special interest in entomology)—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (May 16).

Lecturers (2) in Engineering (with special qualifications in mechanical engineering with particular interest in one or more of the following: fluid mechanics and heat transfer, thermodynamics applied to heat engines, theory of machines, the engineering of chemical processes)—The Registrar, The University, Manchester 13 (May 16).

Physicist in a Ministry of Supply Establishment in S.E. London, to assist in work involving application of electron microscopy to explosives and metallurgical problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.93/53A (May 16).

Professor or Reader in Theoretical Physics, a Professor or Reader in Applied Mathematics, a Reader or Senior Lecturer in Civil Engineering, and a Reader or Lecturer (Grade I) in Metallurgy—The Registrar, The University, Nottingham (May 16).

Research Assistant in Biochemistry, to work on enzymes in connexion with genetics of micro-organisms—The Registrar, University College, Leicester (May 16).

Scientific Officers (with first- or second-class honours degree or equivalent in engineering, physics or mathematics) in the Ministry of Supply, as resident technical representatives at aircraft contractors' works in England—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.213/53A (May 16).

Assistant Lecturer in Physics—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 18).

Chair of Geography in the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 18).

Biologist (with a first- or second-class degree) in the Generation Operation Branch at Headquarters in London, to study the effects of power station operation upon the life of rivers and other waterways, in general and in relation to specific power stations—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1 (May 19).

Head of the Department of Metallurgy, County Technical College, Wednesbury—The Director of Education, Department F.E. County Education Offices, Stafford (May 20).

Lecturer in Pure Mathematics—The Registrar, King's College, Strand, London, W.C.2 (May 22).

Assistant Chemist—The Chief Engineer, Middlesex County Council, Main Drainage Department, Mogden Works, Isleworth, quoting L.951T (May 23).

Lecturer or an Assistant Lecturer in Biochemistry—The Registrar, The University, Leeds 2 (May 25).

Chair of Agriculture in University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 30).

Lecturers in Statistics and Applied Mathematics at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 30).

Lecturer or Assistant Lecturer in Mathematics at University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 30).

Senior Lecturer in Physics, and Lecturers in Botany, Physical Chemistry, Geology, Zoology, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 30).

Lecturer in Economics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 31).

Lecturer in Psychology (preferably with qualifications and research interests in social psychology), a Lecturer in Geography (experience in cartography and field techniques an advantage), a Lecturer in Zoology (preferably with interest in vertebrate zoology or comparative physiology), a Lecturer in Civil Engineering (preferably with interests in hydraulics and soil mechanics), a Lecturer in Biochemistry (preferably with interests in protein chemistry), and a Lecturer in Philosophy, at the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Adelaide, May 31).

Lecturer in Veterinary Pathology—The Registrar and Secretary, The University, Bristol (May 31).

Coke Research Fellowship for research in the Department of Fuel Technology, Ellison Research Fellowships (3) for research in Chemistry or Physics, and C. G. Carlisle Research Scholarship for research in Metallurgy—The Registrar, The University, Sheffield (June 1).

Lecturer or Assistant Lecturer in Pathology—The Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (June 1).

Assistant Lecturer (with an honours or special degree in geology) in the Department of Geology—The Secretary, Bedford College, Regent's Park, London, N.W.1 (June 5).

Senior Lecturer in the Department of Chemistry at University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 13).

PHYSICISTS to work on nuclear induction and in related fields—The Academic Secretary, Weizmann Institute of Science, Rehovoth, Israel (June 15).

RESEARCH STUDENTSHIPS IN SCIENCE—The Registrar, The University, Manchester 13 (July 1).

BIOCHEMIST (senior grade, non-medical)—The Physician Superintendent, Crichton Royal Mental Hospital, Dumfries.

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICER at Royal Greenwich Observatory, Herstmonceux, for recording of cosmic ray intensity and development of photoelectric instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.101/53A.

HUGH WOOD MEMORIAL FELLOWSHIP IN MINING—The Registrar, The University, Leeds 2.

RESEARCH FELLOWSHIP IN MECHANICAL ENGINEERING—The Registrar, The University, Nottingham.

SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent in metallurgy) in a Ministry of Supply Establishment, South-East London, for physical metallurgical research—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.159/53A.

SENIOR LECTURER with qualifications and experience IN CHEMICAL ENGINEERING at Bradford Technical College—The Director of Education, Town Hall, Bradford.

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement*

## Great Britain and Ireland

Proceedings of the Royal Irish Academy. Vol. 55, Section A, No. 4: Solar Eclipses visible in Ireland between A.D. 400 and A.D. 1000. By F. J. O'Connor. Pp. 61–72. 1*s.* 6*d.* Vol. 55, Section A, No. 5: A New Quaternion Approach to Meson Theory. By C. W. Kilmister. Pp. 73–100. 4*s.* 6*d.* Vol. 55, Section A, No. 6: Note on the Production of Pseudo-scalar Mesons. By Rev. J. McConnell. Pp. 101–108. 1*s.* 6*d.* (Dublin: Hodges, Figgis and Co., Ltd., 1952–1953.) [53

Proceedings of the Royal Irish Academy. Vol. 55, Section B, No. 3: Revision of certain Ordovician Fossils from County Tyrone. By F. Cowper Reed. Pp. 29–136+5 plates. 11*s.* Vol. 55, Section B, No. 4: Antituberculous Substances, 9, Long-chain Aliphatic Bases. By Vincent C. Barry, M. L. Conalty and Dermot Twomey. Pp. 137–148. 2*s.* Vol. 55, Section B, Nos. 5, 6: Antituberculous Substances, 10, Oxidation Products of Derivatives of *o*-Phenylene Diamine, by Vincent C. Barry and J. G. Belton; Antituberculous Substances, 11, Some Further Phenazine Pigments derived by Oxidation of *o*-Phenylene Diamine Derivatives, by Vincent C. Barry, J. G. Belton, J. F. Chambers, M. L. Conalty, Rose Kelly and D. Twomey. Pp. 149–164. 2*s.* Vol. 55, Section B, No. 7: The Application of the Barry Degradation to Snail Galactogen. By Proinnsias O'Colla. Pp. 165–170. 1*s.* (Dublin: Hodges, Figgis and Co., Ltd., 1952–1953.) [53

Macaulay Institute for Soil Research. Annual Report, 1951–1952. Pp. 52+2 plates. (Aberdeen: Macaulay Institute for Soil Research, 1953.) [53

Carnegie Trust for the Universities of Scotland. Fifty-first Annual Report (for the Year 1951–52) submitted by the Executive Committee to the Trustees on 23rd February 1953. Pp. iv+80. (Edinburgh: Carnegie Trust for the Universities of Scotland, 1953.) [53

Books for Young People. Group 2: Eleven to Thirteen plus, Annotated and Classified. Compiled by the North Midland and Yorkshire Branches of the Library Association under the editorship of Edgar Osborne. Pp. 123. (London: Library Association, 1953). 10*s.*; 7*s.* 6*d.* to members. [53

Contributions of Science to Peace (Alex Wood Memorial Lecture 1953 delivered in Friends House, London, February 18th, 1953.) By Prof. Charles A. Coulson. Pp. 28. (London: Fellowship of Reconciliation, 1953.) 1*s.* 6*d.* [53

John Innes Leaflet No. 12: Soil Blocks. Pp. 8. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 9*d.* [53

University of London: University College. Annual Report, 1951–1952. Pp. 140. (London: University College, 1953.) [53

Department of Scientific and Industrial Research: Radio Research. Special Report No. 25: Selected Problems in the Preparation, Properties and Application of Materials for Radio Purposes. Pp. iv+24. (London: H.M. Stationery Office, 1953.) 1*s.* 6*d.* net. [53

Negretti and Zambra, Ltd. Seventh Annual Report and Accounts for the Year ended 30th September 1952. Pp. 16. (London: Negretti and Zambra, Ltd., 1953.) [53

## Other Countries

Conseil International des Unions Scientifiques: Union Géodésique et Géophysique Internationale. Association de Séismologie et de Physique de l'Intérieur de la Terre. Comptes rendus des séances de la neuvième Conférence réunie à Bruxelles du 20 Août au 1er Septembre 1951. Rédigés par J. P. Rothé. Pp. xii+288. (Strasbourg: Association de Séismologie et de Physique de l'Intérieur de la Terre, 1952.) [43

Forest Research in India, 1947–48. Part 2. Reports for Burma and Indian Provinces. Pp. iii+75. (Delhi: Manager of Publications, 1952.) 5.4 rupees; 8*s.* 3*d.* [43

Indian Forest Records (New Series). Chemistry and Minor Forest Products, Vol. 1, No. 2: The Vegetable Tanning Materials of India and Burma. By M. V. Edwards, R. L. Badhwar and A. C. Dey. Pp. x+191. (Delhi: Manager of Publications, 1952.) 6 rupees; 9*s.* 6*d.* [43

Bulletin of the Museum of Comparative Zoology. Vol. 107, No. 8: Airplane Observations of Homing Pigeons. By Donald R. Griffin. Pp. 409–440. (Cambridge, Mass.: Harvard College, 1952.) [43

National Research Council: Division of Geology and Geography. Publication 245: Report of the Committee on the Measurement of Geologic Time, 1951–1952. Pp. iii+151. (Washington, D.C.: National Academy of Sciences, 1953.) 1.50 dollars. [43

Fieldiana. Zoology, Vol. 33, No. 2: Mammals. By Colin Campbell Sanborn. (Philippine Zoological Expedition, 1946–1947.) Pp. 87–158. 1.50 dollars. Zoology, Vol. 34, No. 8: On the Mollusk Fauna of the Landlocked Waters of Bermuda. By Fritz Haas. Pp. 101–106. 10 cents. Zoology, Vol. 34, No. 9. South American Non-Marine Shells; Further Remarks and Descriptions. By Fritz Haas. Pp. 107–132. 60 cents. (Chicago: Chicago Natural History Museum, 1952.) [43

Bulletin of the American Museum of Natural History. Vol. 100, Article 3: Avian Systematics and Evolution in the Gulf of Guinea. (J. G. Correia Collection.) By Dean Amadon. Pp. 393–452+4 plates (New York: American Museum of Natural History, 1953.) 1 dollar. [43

Acta Psychiatrica et Neurologica Scandinavica. Supplementum 77: Cerebral Changes following Electrically Induced Convulsions; an Experimental Study on Cats. By Hans Hartelius. Translated from the Swedish by Erika Odelberg. Pp. 128. (Copenhagen: Ejnar Munksgaard, 1952.) 20 Swedish crowns. [43

University of Illinois Engineering Experiment Station. Bulletin Series No. 400: Almost Sinusoidal Oscillations in Nonlinear Systems. Part 2: Synchronization. By Johannes S. Schaffner. Pp. 32. 25 cents. Bulletin Series No. 401: Comparative Performances of a Warm-Air Ceiling Panel System and a Convection System. By Prof. Robert W. Roose, Morris E. Childs, George H. Green and Prof. Seichi Konzo. Pp. 92. 80 cents. Bulletin Series No. 402: A Study of the Practical Efficiency under Static Loading of Riveted Joints connecting Plates. By Prof. Wilbur M. Wilson, Prof. William H. Munse and M. A. Cayol. Pp. 76. 75 cents. Reprint Series No. 49. Progress Reports of Investigation of Railroad Rails and Joint Bars. By R. E. Cramer and R. S. Jensen. Pp. 36. 30 cents. (Urbana: University of Illinois, 1952) [43

University of Helsinki: Institute of Meteorology. Paper No. 71. Theory of the Lag Coefficient of Hygroscopic Hygrometers. By Vilho Väisälä. Pp. 10. (Helsinki: University of Helsinki, 1952.) [43

Beach Erosion Board: Corps of Engineers. Technical Memorandum No. 29. Artificially Nourished and Constructed Beaches. By Jay V. Hall, Jr. Pp. ii+25. (Washington, D.C.: Government Printing Office, 1952.) [43

Fieldiana. Anthropology, Vol. 40: Mogollon Cultural Continuity and Change; the Stratigraphic Analysis of Tularosa and Cordova Caves. By Paul S. Martin, John B. Rinaldo, Elaine Bluhm, Hugh C. Cutler and Roger Grange, Jr. Pp. 528. (Chicago: Chicago Natural History Museum, 1952.) 8 dollars. [43

Copan Ceramics: a Study of Southeastern Maya Pottery. By John M. Longyear, III. (Publication 597.) Pp. xiii+114+72 plates. (Washington, D.C.: Carnegie Institution, 1952.) 5.25 dollars [43

Second Annual Report of the National Science Foundation, Fiscal Year 1952. Pp. viii+77. (Washington, D.C.: Government Printing Office, 1953.) 30 cents. [43

Mauritius Institute Bulletin. Vol. 3, Part 3: Catalogue of the Birds of Mauritius. By F. R. G. Rountree, R. Guérin, S. Pelte and J. Vinson. Pp. 155–217. (Port Louis: Mauritius Institute, 1952.) 5 rupees; 7*s.* 6*d.* [43

Smithsonian Institution. Report of the Secretary and the Financial Report of the Executive Committee of the Board of Regents for the Year ended June 30, 1952. (Publication 4102.) Pp. ix+175. (Washington, D.C.: Government Printing Office, 1953.) [43

Annals of the New York Academy of Sciences. Vol. 55, Art. 6: Use of Antibiotics in Tropical Diseases. By H. W. Brown and 50 other Authors. Pp. 967–1284. (New York: New York Academy of Sciences, 1952.) 3.50 dollars. [43

Académie Royale de Belgique: Classe des Sciences. Mémoires, Tome 27, Fasc. 7: Recherches sur les surfaces algébriques irrégulières. Par A. Andreotti. Pp. 36. 40 francs. Mémoires, Tome 27, Fasc. 8. La tectonique kundelunguienne. Par A. Beugnies. Pp. 128+3 plates. 150 francs. (Bruxelles: Académie Royale de Belgique, 1952.) [43

Union of South Africa: Department of Mines. Geological Series, Bulletin No. 21: Waterberg Coalfield; Records of Boreholes 41 to 100 drilled for the Department of Mines. Pp. 381. (Pretoria: Government Printer, 1951.) 7*s.* 6*d.* [43

Union of South Africa: Department of Agriculture. Science Bulletin No. 305 (Chemistry Series No. 181): Water Requirements of Alluvial Karroo Soil with reference to the Minimum Requirements of Winter Cereals under Irrigation. By M. M. Walters. Pp. iv+35. 6*d.* Science Bulletin No. 313 (Chemistry Series No. 180): The Crude Fibre Content of Sifted and Unsifted Maize Meal. By C. P. Naudé, P. v. d. M. Bruwer and W. P. Pretorius. Pp. 12. 3*d.* Science Bulletin No. 326 (Chemistry Series No. 183): The Toxicity of Pastures after Treatment with Locust Poison. By Dr. C. P. Naudé and Dr. J. P. Van Zijl. Pp. 22. 3*d.* Science Bulletin No. 327 (Chemistry Series No. 184): Meat-marking Inks. By C. H. G. Shutte. Pp. ii+11. 3*d.* Science Bulletin No. 328 (Chemistry Series No. 185): The Use of Brak Water for Irrigation. By H. Klintworth. Pp. 14. 3*d.* Science Bulletin No. 330 (Chemistry Series No. 182): The Effect of Seasons and Years on the Nutrient Content of Spineless Cactus-leaves ([illegible]) picked for Feeding Purposes. By M. M. Walters. Pp. 34. 6*d.* (Pretoria: Government Printer, 1951–1952.) [43

# ROLE OF UNIVERSITIES IN ADULT EDUCATION

WE have already discussed (*Nature*, May 2, p. 759) some general aspects of adult education in Great Britain, and suggested that the time has now come for fresh thinking on the subject. A shrewd contribution to that end has been made by Dr. H. P. Rickman, of the Department of Adult Education in the University College of Hull, in the March issue of *The Fortnightly*. Dr. Rickman is convinced that adult education is the very life-blood of democracy, and believes that the Workers' Educational Association can provide an unbiased liberal education to enrich personalities and produce better citizens. It cannot at the same time, however, extol one social class and claim itself to be its representative, and Dr. Rickman believes that that part of Prof. R. H. Tawney's summons for a return to strong working-class membership of the Workers' Educational Association is mistaken. Objective teaching cannot be based on class education, but should aim at bringing together, rather than separating, the different sections of the community.

The changed character of the Workers' Educational Association, on this view, is an asset and not a drawback. It fits the Association to supplement the educational system of Great Britain without class distinction, which we are beginning to achieve, by providing adult education on the widest possible basis, and in doing so to offer some correction to the deadening uniformity which some quarters are seeking to impose. Dr. Rickman challenges boldly the doctrinaire and flimsy reasons for stressing the narrower 'workers' conception of the movement, and points the way to a fresh advance through bringing imagination, courage and critical thinking to bear on the new problems.

Dr. Rickman's views find some support in the Unesco Survey, "Universities in Adult Education"*, particularly in Prof. S. E. Raybould's study and in the admirable introduction by Mr. C. O. Houle. The latter attempts to bring out the common features and the underlying principles of policy which emerge in Prof. Raybould's account of British experience, Dr. E. A. Corbett's account of university extension education in Canada and that by B. M. Woods and Helen V. Hammarberg of university extension education in the United States of America, which constitute the rest of the book. Dr. Corbett gives us little more than a long list of Canadian activities in this field, with some historical notes. Mr. Woods and Miss Hammarberg make more effort to distil the lessons of American experience; but on the whole it is the diversity of experience and the differences in practice in the three countries that are most manifest from the three separate studies.

Mr. Houle's introduction gives something more than unity to the book: it brings out the relevance at a time when, particularly in Great Britain, the purpose and methods of adult education demand re-examination of the study of foreign institutions in order to determine the basic principles which underlie their effective operation. Although Dr. Corbett's survey does not indicate the cultural differences and historical associations of which full account must be taken in arriving at any such principles, the other two surveys at least offer a tentative approach. Indeed, Prof. Raybould quite as much as Mr. Houle stresses the need for investigation not only into the history of adult education institutions, but also into the nature of the educational process in mature persons. In doing so, moreover, he recognizes the promise which such developments hold—particularly perhaps inquiry into history, psychology, methods and comparative study—for a fuller understanding of the essential nature of adult education, its special problems, and the contribution it may make to the development of democratic societies.

---

* Universities in Adult Education. (Problems in Education, 4.) Pp. 172. (Paris: Unesco; London: H.M. Stationery Office, 1952.) 8s. 0d. net.

To some extent the need for such inquiries has been recognized in the United States also; but, at least in Britain, Prof. Raybould is right in suggesting that along such lines the extra-mural departments of universities may become university departments of adult education in fact as well as in name; while the research itself provides a framework of theory in which the experiments in the training of tutors that most such departments have conducted become an established part of the service rendered by universities to adult education in general. Nor is this the only direction in which Prof. Raybould thinks that the universities could in the future make a distinctive and important contribution. He places first, in fact, the provision, through extension committees, of facilities for students of a different educational and occupational background from that of many Workers' Educational Association students.

In suggesting that this is a field of work for extra-mural departments to cultivate independently of the Workers' Educational Association, and that extension committees, as distinct from joint committees with the Workers' Educational Association, may in future find their chief sphere of activity among the professional classes, Prof. Raybould seems to be ignoring Dr. Rickman's warning and exposing the Workers' Educational Association to further danger of class distinction. Apart, however, from this, it would be a mistaken policy for the universities to concentrate exclusively in their extra-mural work on post-graduate courses of the refresher type. However valuable such courses may be, and although they are undoubtedly proper for a university to provide, such activities should not be undertaken without regard to the other responsibilities of a university towards its region. Selection and discrimination are essential, and it is, above all, important that the universities should not dissipate their available resources by endeavouring to meet all demands made upon them for the provision of adult education.

Mr. Houle, in his introduction to the Unesco publication, formulates five rules which he suggests should guide the universities here. First, the universities should restrict themselves to complex subject-matter: other agencies he considers are better equipped to handle the simpler and rudimentary subjects. Then they should be pioneers, daring in experiment and ready to attempt the pilot study, or in other words to undertake the tasks which voluntary bodies are pre-eminently equipped to attempt. They should provide here, as in other fields, the growing points of society. With these Mr. Houle links the task of training leaders and providing a broad base of leadership at every level of society and in every sphere of activity.

This is clearly a task which in the changed context of the education system of Britain must increasingly fall to the lot of the universities, and accordingly it is important that they should collaborate with the many other agencies in society which provide adult education. An intelligent co-ordination of effort will mean both that the university can illustrate and assist the work of the other agencies, and that it can avoid doing the things which it should not do. Finally, like Prof. Raybould, Mr. Houle suggests that the universities should master adult education as a field of knowledge. The development of research here and the training of leaders will, he recognizes, draw upon and integrate the interests of departments other than education; above all, a dynamic programme of this character demands original thinking and a genuine attempt to re-assess the practices of the past and to adapt them both in relation to the needs of to-day and the resources available.

The universities may well be called upon to make such an effort, and if the recent alarm in regard to the grants for adult education stimulates them to undertake it with some urgency, no harm will have been done. Harm will, however, be done if the stability or the continuance of the extra-mural activities of the universities are endangered, or their planning and development as an essential part of normal university work are hindered. Here, as elsewhere in the universities' work, economy must be practised and retrenchment effected, not on a short-term financial basis, but in relation to the long-term view which alone can avert the disruption and waste caused by sudden and arbitrary cuts.

If, however, the universities are required to consider afresh their precise responsibilities and functions in adult education in view of the widening purpose and growing importance of adult education in general and of the new conditions of to-day, critical thinking and clear vision are equally demanded of the Workers' Educational Association. The Association, moreover, has to reconsider its functions and purpose in the new context, and must face the challenge implicit in the criticism of Dr. Rickman and others. Similarly, we must also expect from the Minister of Education administrative ability, in order to avoid waste of resources and the continuance of means no longer appropriate. Still more, the Minister must have the vision and grasp of essential issues which alone can provide the basis for firm decisions. The committee which is being appointed to make recommendations for the Minister's guidance has a wide field to cover, and the recent discussions will have indicated some of the pitfalls which the formulation of a national policy is likely to meet.

# HISTORY OF SCIENCE

## A Guide to the History of Science

A First Guide for the Study of the History of Science, with Introductory Essays on Science and Tradition. By Prof. George Sarton. Pp. xviii + 316. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1952.) 7.50 dollars.

## A History of Science

Ancient Science through the Golden Age of Greece. By George Sarton. Pp. xxvi + 646. (London: Oxford University Press, 1953.) 63*s*. net.

STUDENTS of the history of science must sooner or later come across the name of George Sarton, either as an author or in his capacity as editor of the international quarterly *Isis*, one of the most widely read periodicals dealing with the subject. *Isis* was founded by Dr. Sarton, and has been edited by him continuously since it first appeared in 1913 until the end of last year. As well as being a prolific writer, Sarton has lectured on his subject at Harvard almost continuously from 1916 until 1951. In fact, he is one of the select few who have been able to make the study of the history of science their life-work. The publication, almost simultaneously, of two new works from his pen is therefore an event of especial interest.

The first of these works, Sarton would like to be known, for citation purposes, as "Horus", an allusion to the fact that Horus is the son of Isis and Osiris, the latter, of course, being the title of the occasional publication closely associated with *Isis*. Certainly, it can be claimed that "Horus" is, in the literary sense, an offspring of these two publications. This new work serves two purposes. The author first seeks to justify his claim that the history of science as a whole, and not simply that of one or other of the individual sciences, should be more widely studied as a major academic discipline. This thesis is elaborated in three introductory essays, in which, also, he indicates the steps he considers necessary to foster and carry out the teaching of this discipline. The essays are followed by an extensive bibliography, covering the subject in the wide sense indicated.

To deal with the bibliography first, the works listed are placed under four major headings, as follows: *A*, History; *B*, Science; *C*, History of Science; and *D*, Organization of the Study and Teaching of the History of Science. The titles under each of these headings are again divided into sub-headings totalling, in all, twenty-six; and finally each of the secondary headings is further sub-divided. Of the secondary headings, we may mention, as examples, under (*A*), historical methods; under (*B*), scientific methods and the philosophy of science, catalogues of scientific literature, general scientific journals, and national academies and scientific societies; under (*C*), treatises and handbooks on the history of science, history of science in special countries, history of special sciences, journals and serials concerning the history and philosophy of science (with a useful addendum of "Misleading Titles"); and, under (*D*), national societies devoted to the history of science, and the teaching of the history of science. A short introductory note precedes each of the twenty-six main sub-divisions, and many of the individual entries are annotated. Further assistance to users of the bibliography is given by an author index containing upwards of 1,500 names. It is expected that the book will be used mainly by English-reading students, and their needs are given priority by listing suitable books in English, or in English translations, whenever possible. If such are not available, then, in the case of texts in the less familiar languages, French or German translations have been given preference over the originals. The author has refrained almost entirely from the temptation to add remarks critical of particular entries, but has, wherever possible, given references to the critical reviews or short notices published in *Isis*, a course which is probably more satisfactory from the student's point of view.

The bibliography is based primarily on the author's own library, and is supplemented from the bibliographies regularly published in *Isis* (which, by now, it is claimed, must include some 75,000 entries). Some idea of its scope can be gained from the fact that it occupies about 250 pages, and that the number of titles approaches 2,000. At the same time, no claim is made that it is exhaustive, and readers familiar with the subject in general, or specialists in the history of particular sciences, will doubtless call to mind some works that, in their opinion, might deservedly have been included. The author disarms criticism on these grounds with the statement that a general bibliography of this sort cannot do more than assist a scholar; and adds the sound advice that, though every investigation should begin with a bibliography, it ought to end with a better one.

It is regrettable that the author has found it necessary, on the score of labour and expense, to exclude biographies of scientists. These often provide valuable material for students. Users of the bibliography are advised to make their own lists, but this is not an easy task for the inexperienced, particularly if living out of reach of a first-class reference library. Apart from this criticism, the book admirably fulfils the purpose expressed in its full title. It is an excellent guide to the history of science, and is believed to be the only book of its kind. To obtain the information here compressed between the covers of one conveniently sized book, it would be necessary to search the pages of *Isis* for the past forty years. It should prove extremely valuable to students, research workers, teachers, librarians, and in fact to all in any way interested in the history of science, or some special branch of science.

A notice of "Horus" would not be complete without some further reference to the three introductory essays that occupy the first sixty pages or so. These are based on three lectures delivered by the author in Europe, with the express object of explaining the meaning and purpose of the history of science. In the first, entitled "Science and Tradition", Sarton discusses the revolutionary change that has resulted from the major scientific discoveries, not only in our way of life, as a result of their practical application, but also in our outlook on the world as a whole, and on the universe around us. The change, he states, though it has taken place slowly, is one from a science ancillary to theology, or divine revelation, to the modern conception of science as the search for truth irrespective of its consequences. Sarton's fear is that, accompanying this change, the destruction of good traditions is taking place concurrently with the elimination of the bad ones. He is apprehensive that we are passing into an age in which the rule of technocrats rather than that of true scientists is in the ascendant. He concludes this lecture by pointing out that, while most educated people realize the need for the study of history for political purposes, they do not yet realize its function in the reconciliation of science with the humanities, or for the humanization of science.

The second lecture has a somewhat misleading title, "The Tradition of Ancient and Mediæval Science", and might more aptly be called "The Transmission of Ancient Science through the Ages". In it the author discusses the fragmentary and incomplete state of our knowledge of the science of the ancients, that is, broadly speaking, of science as it existed before the invention of printing stimulated the accurate recording and wide distribution of knowledge. Much has been lost, but it is still possible that our knowledge of this early period may yet be enlarged through the patient study of old manuscripts and inscriptions by philologists and archæologists.

Sarton hopes, by means of his first two lectures, to persuade his readers that it is worth while teaching the history of science; but he admits that acceptance of this view will not be universal, and may not be general. In his third lecture he discusses whether, in fact, it really is possible to teach the history of science, as a whole, as distinct from the histories of particular sciences, which, not surprisingly, have a much wider appeal. He indicates the nature of the opposition likely to be encountered. There are, first of all, those who reject the past as something not worth worrying about, being permanently finished. Secondly, there are those scientists who realize the importance of political and social history, but are not interested in the history of science, because the scientific ideas of the past are definitely inferior to those of the present, and therefore would not repay the effort of studying them. They are concerned only in the perfectibility of science. These two groups, Sarton feels, are historically blind, and there is no hope of overcoming their lack of interest.

Into a third group Sarton places those ignorant, and therefore dangerous friends, men of science. perhaps a majority, who admit an interest in, and may even be enthusiastic about, the history of science, but scarcely realize the necessity of studying it. They regard it as a relatively simple matter, and uncritically accept as good any book on the subject (how they can do otherwise without making a special study of the subject is not stated). This latter class, Sarton claims, quite fails to realize the difficulties in the way of arriving at truth in historical matters; or that, though history may be easy to read, it does not follow that it is easy to write. Sarton thinks they will only too readily answer that it is possible to teach the history of science, but will dismiss it as a task so easy that it can safely be left to inferior minds.

Sarton's thesis is that historians of science must know both science and history, and that the most perfect knowledge of one is insufficient without some understanding of the other. He claims that a historian of culture is not qualified to discuss the history of science if he lacks any kind of scientific training and, similarly, that even the most distinguished men of science are not qualified to discuss the history of their subject if they lack historical sense. Good intentions are not enough, and, Sarton states, there are few historians of science fully qualified for the task of teaching their subject. It is all a matter of training; but the training, if different from that ordinarily required for a historian or a scientist, is not necessarily more difficult. Nevertheless, if it is to be taken seriously, there can be no doubt that the history of science as a whole must be regarded as a major discipline.

This is the counsel of perfection, but it is a thesis that ought ultimately to receive universal acceptance, as general interest in and knowledge of the history of science grows, and there are encouraging signs that it is growing, even among professional historians.

Sarton's other, his latest, work on the history of science goes back to the Golden Age of Greece, when philosophers had more time to think, talk and speculate. Those who know the author's earlier three-volume "Introduction to the History of Science" will, no doubt, wish to know what is the relation of the latter to this new product of his pen. The "Introduction", a work covering the period from antiquity up to A.D. 1400, is an elaborate treatise and bibliography, a reference work not intended as a book to be read straight through. The new work, on the other hand, is intended to meet the needs of students and general readers, rather than those of the research worker. It contains the essence of the course lectures given by Sarton at Harvard during the past thirty years or so. Though complete in itself, it is only the first of a series of eight volumes in which the author intends to take his reader up to the present day, and covers, in time, only the period from the dawn of history until the end of the fourth century B.C. It specifically excludes any special study of early Hindu and Chinese science, not because these are without importance, but on the ground that they lack significance for Western scientists, whose thinking has been influenced mainly by Hebrew and Greek thought, and scarcely at all by that of the Chinese and the Hindus.

This book cannot be noticed in detail here, but the name of the author is sufficient guarantee that perusal will be rewarding; and industrious readers will no doubt look forward to the appearance of the further volumes promised. They will form a fitting monument to Sarton's life-work.

---

# BIOCHEMISTRY OF PHOSPHORUS COMPOUNDS

## Phosphorus Metabolism

A Symposium on the Role of Phosphorus in the Metabolism of Plants and Animals. Vol. 1. Sponsored by the McCollum–Pratt Institute of the Johns Hopkins University. Edited by William D. McElroy and Bentley Glass. (Contribution No. 23 of the McCollum–Pratt Institute.) Pp. xv+762. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1951.) 80s. net.

EVEN the briefest account of major advances in biochemistry during the past two decades could not fail to include the developments in the chemistry and physiology of phosphorus compounds; for in this field we have witnessed truly spectacular progress. Looking back, however, one cannot but be impressed by the successive changes in the attitude of biochemists towards the role and the mode of action of phosphorus compounds in Nature. Thus, for example, about 1930, it was popular to discuss the concept of 'energy linkage' ('energetische Koppelung'); this notion, while it attributed to a phosphorus-containing coenzyme such as adenosine-triphosphate the position of an agent which plays a part in energy exchange, did not, however, provide any material basis for the actual mechanism of this process. From 1934 onwards that somewhat vague idea of 'energy linkage' acquired a new meaning with the discovery of the 'Lohmann reaction' and 'Parnas reaction', when it was demonstrated for the first time that adenosinetriphosphate is involved in a direct intermolecular shift of phosphate groups, from the phosphorylated intermediary products of glycogenolysis to creatine. For some years following these findings the term 'energy linkage' was largely abandoned in favour of the concept of 'chemical linkage'; before long, however, it emerged again (1941), this time in an entirely new guise, with emphasis on the phosphate bonds in adenosinetriphosphate as the site at which the free energy is stored, and whence it can be dispensed in response to the demands of metabolic processes.

Another significant change concerning the phosphorus-containing coenzymes, which began to take shape more recently, has been the growing awareness that the function of these substances is by no means restricted to the metabolism of carbohydrates, but that they are instrumental also in the decarboxylation and transmethylation of amino-acids, the synthesis of peptide bonds, carbon dioxide fixation, photosynthesis, oxidation of fatty acids, formation of acetylcholine and certain other acetyl-transfer reactions. In fact, with discoveries in the field of phosphorus compounds and phosphorylations following each other at an ever-increasing pace, there remains scarcely a branch of biological chemistry which could claim to have escaped their impact. Nothing can illustrate the above statement in a more realistic and convincing manner than the symposium on phosphorus metabolism held in June 1951 at the McCollum–Pratt Institute in Baltimore, the proceedings of which have now appeared as a book containing no fewer than fifty papers dealing with different aspects of phosphorus metabolism in plants and animals. These are by no means conventional review articles. They are surveys by specialists who were recruited from among active investigators intent on reporting and discussing not so much what was being done by others, but rather the results of their own original research. Each subject is introduced on a broad basis by one speaker, and then elaborated further by additional contributions of several other investigators.

The subjects thus covered include the metabolism of polysaccharides and disaccharides (Hassid, Doudoroff, Hehre, Sutherland), fructose (Slein, Taylor), hexosephosphates (Leloir, Cohen, Lipmann), triosephosphates, pentosephosphates (Horecker, Racker, Dische) and nucleosides (Lampen, Schlenk); the biochemistry of inorganic pyrophosphates and metaphosphates (Schmidt), coenzyme A (Novelli), pyridoxal phosphate (Gunsalus) and uridine pyrophosphate compounds (Park); the metabolism of phosphorus-containing coenzymes (Kornberg); the role of inorganic ions in phosphorylations (Lardy, Najjar); thermodynamics of phosphate bonds (Lipmann, Oesper, Koshland); a series of articles on acetyl-transfer reactions (introduced by Barker), and another on oxidative phosphorylations (Hunter, Green, Lehninger and others); and finally, a number of particularly interesting papers grouped together under the title of "Utilization of Phosphate Bond Energy in Biological Systems", which includes contributions on muscular contraction, bioelectricity, bioluminescence, synthesis of peptide bonds, carbon dioxide fixation and transmethylations.

The symposium exhibits several commendable features; in particular, it deserves praise for the skilful avoidance of overlapping in the treatment of the various subjects, and the care with which it has been edited and published; the inclusion *in extenso* of the discussions greatly enhances its value, especially to those actively engaged in this or in allied fields. It can be said without exaggeration that in its peculiar collective form it is one of the most comprehensive treatises on the subject of phosphorus metabolism available at present. T. MANN

# CLIMATOLOGICAL MAPS FOR THE BRITISH ISLES

## Climatological Atlas of the British Isles

(Air Ministry: Meteorological Office. M.O. 488.) Pp. vii+139. (London: H.M. Stationery Office, 1952.) 52*s.* 6*d.* net.

A COMPREHENSIVE climatological atlas of the British Isles has long been awaited, for, since the days of Buchan, Mill and Bartholomew, a steadily growing mass of standardized observations has arisen to satisfy the public need. In this atlas the incidence and distribution of ten major climatic elements—pressure, wind, temperature, rainfall, snow, thunder, humidity, sunshine, visibility with fog, and cloud—are very thoroughly delineated in upwards of a hundred and fifty maps and diagrams, printed with clarity and effective colouring. A folding orographical map can be opened for comparison with those of climate, which abound in material for discussion. There is, for example, a splendid set of maps of average means of relative humidity at 13.00 hr. whereon the moist atmosphere of eastern Ireland gives food for thought. Likewise, the unpleasing frequency of winter fog on the Great North Road from Newark to Ferrybridge is sternly revealed.

Climatological mapping for islands so diversified is not easy; on the whole, the compromise here adopted is effective. Yet the drawing of isopleths among an irregular scatter of observations subject to numerous environmental variables is a geographer's technique which is not everywhere evident. Many readers will turn with interest to some of the smaller maps—for example, the enterprising effort to show the average date of the first and last screen frost (p. 48). Misapprehensions may arise here; air masses being what they are, the chances of early and late frosts in the potato country of south Lancashire are, in my opinion, unlikely to be represented by the isopleths here given. Scrutiny of recent data from Strathy or Kettins will soon show that the bleak pastures of Caithness or the broad ploughlands of Strathmore are not given fair representation by the map on p. 49, which shows them receiving less than half the number of frosty nights ascribed to the Eden valley. Maps showing absolute extremes (p. 47) are open to similar criticisms; they might reasonably have been extended to include more stations over a longer period.

Representative temperature data are, however, difficult to choose and map, and the like applies to other climatic elements; moreover, caveats are entered in the text (for example, pp. 31 and 128). Future editions might include diagrams giving approximate corrections for altitude or site factors, as the effects of the latter are tolerably constant. Some further representation of the variability of monthly rainfall would be welcome.

Among minor points, on p. 29 the November extreme up to 1940 should be given as 70° F.; on p. 117 the choice of Cullompton's 1,101 hours of sunshine in 1912 as "lowest on record" is odd when in the same year many stations had both lower totals and lower percentages. On p. 133 the same order of tints has been used to grade both visibility and fog. Misprints, for example Marton on p. 80, are very rare.

The success of the many maps must be set against the few open to criticism. Numerous detailed maps and tables—for example, those showing exceptional rainfalls, sea-breeze effects, and frequency of low cloud and sunny days—are welcome and opportune. Admirable informative notes and useful references are added. The diversity and clarity of the material thus officially presented render this atlas not only indispensable as a reference but also good value; minor points can easily be remedied in a second edition. Such an atlas provides a lively stimulus to all who would discuss the future welfare of Great Britain.

GORDON MANLEY

# INDIAN VIEWS ON PLURAL SOCIETY

## Caste and Class in India

By Prof. G. S. Ghurye. Pp. vii+246. (Bombay: Popular Book Depot, 1950.) 15 rupees.

## Group Prejudices in India

A Symposium. Edited by Sir Manilal B. Nanavati and C. N. Vakil. Pp. 223. (Bombay: Vora and Co., Ltd., 1951.) 17*s*. 6*d*.

PROF. G. S. GHURYE'S "Caste and Class in India" is in effect a second edition of his "Caste and Race in India", published in the "History of Civilization" series in 1932. The chapter (5) on "Race and Caste" in that first edition, and the appendixes which related to it, have been, wisely on the whole, omitted in the present volume, and hence no doubt a change has been necessary in the title. Chapters 8 and 9 in the first edition, called there "Caste: Recent and Contemporary" and "Conclusion", are expanded into Chapters 7, "Caste and British Rule", and 8, "Caste and Nationalism", a ninth chapter being added on "Class, its Role", while there are some other additions in earlier chapters. The first four chapters still constitute an excellent conspectus of the caste system, which Prof. Ghurye is admirably qualified to give, and these form the most valuable part of the book. On the elements of caste outside India he is not quite so happy, as his insistences on parallels with Rome and with medieval Europe, for example, are not really valid. Class distinctions are world wide and have not infrequently involved some restriction of, or even prohibition of, intermarriage between classes; it is the peculiarly Indian element of taboo involving pollution and consequential purification which distinguishes caste from mere class. Prof. Ghurye correctly states that Anglo-Saxon laws laid down a rule of endogamy, but there is very good reason to suppose that 'laws' of that kind merely laid down what the lawgiver regarded as an ideal of behaviour; and, in any event, to go on to say that "by the fifteenth century in England this rule of endogamy had almost vanished" gives a very false impression of English society from the time of King Alfred onwards, to say nothing of any changes due to the Norman Conquest, when Anglo-Saxon laws were superseded by Norman. When dealing with the origin of the caste system, Prof. Ghurye seems to lay too much emphasis on the racial factor, which by itself would no more have given rise to a caste system in India than it has done anywhere else.

In his chapter on "Caste and British Rule", the author indicts the British for not having taken more effective measures to abolish caste and for not having ignored caste in its recruitment to Government service, a policy which, if pursued, would have filled the southern Indian services, at any rate, with Brahmans to the virtual exclusion of other castes. But discriminative recruitment was probably an inevitable corollary of abstention from anti-caste legislation, and that is a measure which, in view of the religious sanctions of caste-observance, would have been contrary to the pledge given by the Crown in 1858, and could in any event only be successful if undertaken by Indians themselves, since caste is still an integral factor in Hindu society, and very strongly entrenched there. When Prof. Ghurye states that ever since the Indian Mutiny "the Indian Army has been studiously purged of the higher castes", he is making a flat misstatement, since many Rajputs and some Brahmans have continuously played an important part in the composition of the Indian Army. Actually lower- (not higher-) caste Hindus had been eliminated from the Bengal Army by 1893, when the 'class' system of recruiting was restored, so that whole regiments consisted uniformly of Brahmans, or of Rajputs, etc. The final chapters amount in effect to an exhortation to abolish caste, and the author is to be commended for realizing that an attempt to return to the four *varna* of the Vedic age, as recommended by Mahatma Gandhi, would be no less detrimental if achieved than it is actually in practice impossible. But he should be more careful in his use of authorities at second hand; a failure to verify his references has led him to ascribe to Sir F. Bartlett words which, though doubtless he would agree with their content, he most certainly never expressed.

Prof. Ghurye is also one of the thirty-one contributors to "Group Prejudices in India: a Symposium", edited by Sir Manilal Nanavati and C. N. Vakil. This volume has the very commendable purpose of focusing the attention of the Indian public on the causes of tension, rivalry, and antipathy between cultural, religious, and economic groups so numerous in Indian society. The contributors are divided into six sections: culture and prejudices, religions and prejudices, social prejudices, politics and prejudices, minorities and prejudices, and miscellaneous. Unfortunately, the contributions are extremely uneven and, together with a few objective and useful contributions to the study of, and therefore towards the elimination of, prejudice, there is some sermonizing, a good deal of rather frothy platitude, and some sheer fustian. Generally speaking, the contributors blame Great Britain for encouraging group antagonism by a deliberate policy of 'divide and rule', and although the editors point out that the political unity of the Indian peninsula was first brought about by British rule, one contributor goes so far as to accuse the British of having deliberately created in 1917 the non-Brahman versus Brahman antagonism in south India, which had become vocal at least as early as 1840. Writers seeking to eliminate prejudice would carry more weight and sound more convincing if they refused to be blinded by it themselves.

J. H. HUTTON

## Wörterbuch der mathematischen Wissenschaften

Band 1: Deutsch–Englisch. Von Dr. Leo Herland. Pp. 235. (London: Hafner Publishing Co., Ltd., 1951.) 24*s*.

THIS book is a first attempt to fill a need long felt by mathematicians for a specialized technical dictionary. It will be of considerable help to research students who, with little previous knowledge of German, are faced with the task of reading a good deal of mathematics in German, such as the "yellow-backs" or "Ergebnisse" tracts. The book is well produced. A large type has been used in the printing, and this makes for unusual clarity. Numerous cross-references are given under many of the key words which occur in widely differing branches of the subject, and altogether the author has produced a commendable and relatively complete work.

However, there are some serious omissions, such as the following. The words *Verband*, *schlicht*, *Zelle* and *Spaltung*, all commonly occurring in non-specialized branches of mathematics, are missing. In geometry, which the author curiously emphasizes by separating it from the main stream of mathematics, the omissions are particularly serious. Examples are *Hauptdreikant*, *Doppelgeschlecht*, *Leitkurve* and *Restschnitt*. It would help a geometer if, under cross-referencing, the words *Konstantenzahl*, *Hullflache* and *adjungierte Fläche* appeared. And what about *abzählende Geometrie*? This does not appear under *Geometrie*, and for *abzählen* the meanings given are 'count, denumerate', but not the usual translation 'enumerate'. Incidentally, I cannot find the verb 'denumerate' in the "Oxford Concise Dictionary", so this translation of *abzählen* is not to be recommended on the grounds of common usage. Another word, *Auflösung*, is used in algebraic geometry to refer to the 'resolution' of singularities, but no cross-reference to this is made. Apart from omissions such as these, there are some incorrect translations: *perfekt* (algebra) should be 'complete', and *mehrdeutig* in function theory is, literally, 'many-valued' and not 'ambiguous'.

If these omissions and errors can be rectified in a second edition, the book should be in great demand among mathematicians. L. S. GODDARD

## Physics as a Career

By Norman Clarke. Pp. 70+9 plates. (London: Institute of Physics, 1952.) 6*s*. net.

THE author of this book, Mr. Norman Clarke, is the deputy secretary of the Institute of Physics and he has spent most of the past seven years, as he reminds the reader in the preface, talking, writing and listening to physicists, intending physicists and employers of physicists; this fact should be sufficient to commend the book as a useful and authoritative guide to those seeking a career in physics. In addition, as many members of the Institute can testify, particularly those who have consulted Mr. Clarke with regard to problems concerning salaries, conditions of employment and training, and in connexion with applications for posts as physicists, his sound advice and wide experience have been invaluable. His knowledge with regard to these matters is now made available to a wider public, and it is to be hoped that it may stimulate those who have the talents to study and take up professional careers in physics.

The author deals briefly, in separate sections, with physics and its applications, professional education and qualifications, posts in industry, the universities, government service, technical colleges, schools, research associations and work as hospital physicists. Details of the salaries and prospects of promotion in these various posts are clearly stated. In the four appendixes, useful factual information regarding technical colleges recognized by the Institute of Physics as training centres, and the various research associations of the Department of Scientific and Industrial Research, is given, in addition to a short bibliography of books about science, and the addresses of the various physical societies and associations of physicists. The illustrations are interesting and lend tone to the book, but are superfluous to the text.

## Under the Red Sea

By Hans Hass. Translated from the German by James Cleugh. Pp. 208+47 plates. (London: Jarrolds Publishers (London), Ltd., 1952.) 16*s*. net.

CONSIDERABLE publicity is being given in the popular press to the possibilities of leaving this earth to explore worlds beyond our own. Much more accessible than Mars or the moon, however, is a world on which man has still barely set foot: the world beneath the seas, where "the surface of the water is the sky . . . and the waves are its clouds". The fascination and enchantment of it can be judged from some of the superlative photographs which liberally illustrate this book by Dr. Hans Hass. Outstanding are a series of nine pictures of the manta, *Manta birostris* Walbaum. Very great credit, too, must be given to the author's courage and considerable swimming skill in obtaining these.

Unfortunately, it is the photographs alone which commend "Under the Red Sea" to the serious attention of biologists. The text contains little of scientific worth and presents, for the most part, a rather trite and superficial account of the author's brief acquaintance with the Sudan, the Sudanese and its British officials. Quite unexpectedly, however, there are here and there passages of vividly descriptive writing, as when he portrays some exquisite coral land- (or sea-?) scape, or in describing the sensations of being alone in this underwater world with a myriad of animals of unknown habits. At such times he writes with a passion for this environment as great as that of a countryman writing of the countryside he loves. ALAN J. BROOK

## Les négritos de l'Ile de Luçon (Philippines)

Par Dr. E. Genet-Varcin. (Ouvrage publié sous les auspices de la Société d'Anthropologie de Paris.) Pp. 260. (Paris: Masson et Cie., 1951.) 1200 francs.

THIS is a study of the pygmy skeleton, with special reference to material from the Philippine island of Luzon. The material consists of the remains of fifteen adult males, fourteen females, two adolescents and five infants and is probably the most complete collection of Negrito skeletons yet made, or ever likely to be made. It is a great pity, therefore, that the measurements of the individual crania and other bones have not been included, as this omission makes the publication useless for comparative studies making use of modern biometrical techniques. Mean measurements when based on such a small sample can be very misleading, and this criticism applies even more strongly when they are compared with means relating to other groups of pygmies where the numbers on which the means are based are even more inadequate—in some cases merely a single specimen. Any conclusions derived from this study must therefore be regarded as hypothetical until they can be supported by more complete data.

G. I. JONES

# SCIENTIFIC INSTRUMENTS FOR RESEARCH AND INDUSTRY

## PHYSICAL SOCIETY'S EXHIBITION, 1953

THE thirty-seventh annual exhibition of scientific instruments, organized by the Physical Society, was opened by the president of the Society, Prof. R. Whiddington, on April 13. After thanking the governors and heads of departments of the Imperial College of Science and Technology, London, for continuing to allow the use of the College for the purposes of the exhibition, he remarked, "I feel certain that those whose hospitality we enjoy feel, with the Council of the Physical Society, that this exhibition not only meets a need but also does a most useful service to the community which we are all in our several ways trying to serve. . . . Whenever, in recent years, I look through the Handbook, I am reminded of the time when, as a young man, forty years ago I started research at the Cavendish Laboratory, Cambridge, on a topic to do with electrons. I was warned by certain well-meaning friends of the serious mistake I was making in entering a field destined in the near future to become arid, dull and uninteresting. How wrong they were ! In looking through the 300 or more pages of our Handbook, what a large number of exhibitors are connected in one way or another with applications of particle physics, in particular electron physics. This is not the time or place for me to compare the work of the modern electron physicist with that of his forbear in physics of the last century, though it is interesting to reflect even for a moment, as I hasten to say we are now doing, on the many similar principles used in both eras. The results to-day are really staggering, whether you look at the university laboratory devoted in the main to research for its own sake, or the industrial and service research laboratories where equal fun and interest is to be found, but where applications are made more directly to human amenities and defence. I firmly believe, and I am sure that all with knowledge of the position will agree with me, that this exhibition does much to show the scientific world what apparatus and instruments are available—and what books are available—to help in the great work".

The exhibition was open for five days, April 13–17 inclusive. The numbers attending amounted to twenty thousand, their entry being automatically recorded as 'persons per minute' during every minute while the exhibition was open, that is, from 10 a.m. to 8 p.m. including the lunch hour. This time only one exhibit was housed in the Huxley Buildings, the main exhibition being staged in the Imperial College.

Three discourses were delivered by eminent scientific authorities : (1) "Seismic Study of the Ocean Basins", by Dr. E. C. Bullard, director of the National Physical Laboratory, Teddington ; (2) "Particles, Pellicles ; Pigments, Paints and Physics", by Dr. L. A. Jordan, director of the Paint Research Station, Teddington ; and (3) "Scintillation Counting and its Medical Applications", by Prof. W. V. Mayneord, head of the Department of Physics, Royal Cancer Hospital, Fulham Road, London.

Dr. Bullard's discourse was given on Tuesday evening, April 14. After referring to geological methods used in studying the solid earth above sea-level, he pointed out that direct information about the geological structure of the floor of the deep oceans is necessarily meagre. The rocks are not only hidden under several miles of water, but are usually also covered by several thousand feet of sediments. Oceanic geology has therefore to be carried on by indirect methods, and conclusions drawn from the frequently ambiguous indications of gravity, magnetic and seismic measurements. Of these, the seismic give the most detailed information. The first marine seismic observations were made before the Second World War in the relatively shallow seas covering the continental shelf on both sides of the Atlantic. Since the War the work has been extended to the deep oceans, and results of great interest for geology have been obtained. In shallow water the instruments can lie on the bottom, but in deep water this becomes impracticable and a method is used in which both the explosive and the receiving device are suspended at a depth of only a few hundred feet from the surface. The receivers are hydrophones hung beneath buoys fitted with radio-transmitters. Results have been obtained up to distances of 80 miles using only a few hundred pounds of explosive. They show the structure of the greater part of the oceans to be quite different from that of the continents. The discontinuity which occurs at about 35 km. under the continents, and represents the base of the earth's crust, is only about 5 km. below the floor of the oceans. The sediments in the oceans are not so thick as had been generally supposed and are usually less than 3,000 ft. in thickness, as compared with 8,000–16,000 ft. over the continental shelf. From the measurements of velocity in the various layers below the ocean, the 5-km. layer of rock underlying the sediments is supposed to be basalt (velocity 6·5 km./sec.), whereas the deeper-lying basic rock, having a higher velocity of sound (8·1 km./sec.), is probably olivine. The results at present available represent only a few points scattered over a vast area, but nevertheless are of great significance for geological theory.

The second discourse, by Dr. L. A. Jordan, was given on Wednesday evening, April 15. He illustrated the importance of physical considerations in research applied to paint technology, by noting the transition from the general particle to the particular pigment in terms of crystalline nature and structure, and the effects of refractive index and other physical conditions on colour and special properties as well as on general behaviour. Similarly, considerations of the media used in paint technology were shown to bring in rheological considerations and other aspects of classical physics. It was shown that particle size has a profound effect on the colour shade of a pigment, and that large apparent variations of colour can be produced as the colour of the background is varied. Dr. Jordan directed attention to the infra-red and ultra-violet reflexion from paints and referred to the importance of these factors on the painting of tanks exposed to desert heat, and to ships' camouflage. Viscous and elastic properties of paints can be measured by a torsion pendulum method, and the weathering properties were illustrated by electron microscope photographs. In considering the flow properties of paints, it was pointed out that they are non-Newtonian fluids showing thixotropic behaviour. The conjunction of pigment and medium, constituting paint, brings notable forces into play. Examples were shown of carbon black in oil forming equispaced parallel 'diffraction' lines, mottling effects during flotation, and the effects of temperature gradients during flotation. Pigment flotation in paints regarded as a dynamic phenomenon has been the subject of special study at the Paint Research Station. A cinematograph film illustrating this work was shown. A striking effect 'like oil on troubled waters' was shown when a trace of silicone fluid was introduced into the surface of a pigment–oil mixture, all trace of cell formation (mottling) being immediately destroyed.

Prof. W. V. Mayneord delivered the third discourse on Thursday evening, April 16. He pointed out that the use of crystalline and liquid scintillating media in conjunction with electron multipliers has now become an important technique in modern physics. He outlined the development of the subject and discussed the underlying physical principles. The high sensitivity of the system for a detector of small linear dimensions makes the method applicable to a number of important problems. As a proportional counting system, the scintillation method has applications in gamma-ray and particle spectroscopy. Prof. Mayneord described applications of scintillation counting to the detection and measurement of radioactive isotopes introduced into the human body, including recent attempts to form visual and photographic images of the spatial distribution of radioactive materials. The importance of such applications to cancer research is obvious.

---

Details of the exhibits and demonstrations staged by about 150 exhibitors are to be found in the Physical Society's "Handbook of Scientific Instruments and Apparatus, 1953"[*]. This handbook is essentially a reference book, well printed on art paper and profusely illustrated by half-tone reproductions, valuable to all those interested in the use of scientific instruments in industrial, 'service', or academic research and in the teaching of science in schools and technical colleges. The exhibits cover the whole field of scientific instruments and the materials used in their construction; the exhibitors include a large number of industrial firms, the government research laboratories and some university laboratories.

On this occasion a tour of the exhibition revealed a welcome increase in the number of 'dynamic' exhibits (that is, demonstrations, or working models) relative to 'static' (that is, not functioning) exhibits. Although there is, of course, much of interest in static exhibits, a simple demonstration is always more attractive and often more convincing. With such a large number of interesting exhibits it is not possible in this brief review to mention more than a few, picked more or less at random. Inventive ingenuity was often displayed not only in the instruments themselves but also in their names, for example, holiday detector, psophometer, xerograph, etc. A 'holiday' is, in fact, a pin-hole in the protective coating of a steel pipe-line. If such pin-holes are not detected and filled before the pipe is buried in the ground, they form a possible source of corrosion. Pre-heating the gas and air supply to a bright-red heat makes it possible to use a gas–air hand-torch to melt a 1-mm. diameter platinum wire. The torch is very convenient for brazing and copper-soldering. A reciprocating drill operated at ultrasonic frequency, using a magnetostrictive transducer at 22 kc./sec., is used for the rapid drilling and cutting of brittle materials when a paste of carbide abrasive is fed to the vibrating tip. The absence of any rotary motion renders this type of instrument particularly useful for drilling holes of any required shape and for making cuts and depressions in materials which are difficult to machine by more conventional methods. A square hole was cut in a thin plate of glass in a minute or so. Two types of watch rate-recorder were exhibited, the first being a cathode-ray tube indicator and an oscillator of variable frequency adjusted in such a manner that the rate of the watch could be read off directly from a dial. The second type is a printing machine, which records the watch ticks on a tape carried by a small synchronous motor controlled from a crystal oscillator. This system not only gives the rate of the watch but also permits of detection of faults in the movement to a high degree of accuracy. The Science Museum, South Kensington, exhibited the original Milne–Shaw seismograph designed in 1914; instruments of this type are easily maintained and are used extensively for general recording purposes at seismological stations throughout the world. As usual, a wide range of vacuum pumps and vacuum equipment accessories was on view.

A demonstration was provided to illustrate the strain-free cutting of soft metals when it is desired that the cut edge shall be free from strain, as in the X-ray determination of preferred orientation. The method consists in the removal of positive ions from the workpiece by an electric condenser discharge across a small gap to the cutting electrode and quenching the discharge in oil. This produces a precision cut, free from strain. A general purpose digital computer for mathematical and scientific work employed a rotary magnetic disk as a 'store'. Dynamic storage in the registers of the arithmetic units was obtained by magnetostriction delay lines. With this arrangement combined with an electric typewriter, tables of sines and cosines for every degree up to 90° could be worked out in a few seconds and typed out to nine places of decimals in a few minutes. The high speed of the machine was also demonstrated in tabulating the second, third and fourth powers of numbers. The Imperial College Mathematics Department demonstrated a large automatic computing machine performing all the basic operations of arithmetic on 20-digit binary numbers. This was housed in the Huxley Building, Exhibition Road. The Hydraulics Research Station (Department of Scientific and Industrial Research) exhibited a wave-height analyser in operation. This device measures each wave from a trough to the following crest using a series of probes dipping into the water. The result is recorded as a count on one of thirty-two telephone message registers and stops after 300 waves. The effective wave-height and the height distribution can then be determined. A roundness-measuring machine for examining the roundness of such parts as balls and rollers, ball and roller races, pistons and cylinders, with electrical indication of departure from ideal was shown to give magnifications of inaccuracies in steps from 50 to 10,000. An ingenious device for measuring air flow (as a spirometer for use with small animals) was shown by the Chemical Defence Research Establishment (Ministry of Supply). The air-flow carries a soap film along a tube towards a pair of electrodes at the exit end. Connexion of the electrodes by the soap film operates a relay and counting system which records the event, breaks the film and creates a new film at the inlet end of the meter. Another demonstration by this Establishment showed how large drops of liquid can be freely supported in an upward stream of air. The technique employed for this purpose has been used successfully in an investigation of the mechanism of atomization when freely supported drops are shattered by high-speed air streams.

---

[*] Handbook of Scientific Instruments and Apparatus, 1953, as shown at the 37th Physical Society Exhibition. Pp. xii+262+A72. (Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.) 6s.; by post, 7s. 3d.

In the ultrasonic field a number of exhibits showed the latest developments in barium titanate transducers for flaw detection, high-power treatment of liquids, etc. It is well known that the amplitude of a tuning fork must be constant to maintain an accurate frequency. A fork was shown which incorporated a novel device for maintaining a constant amplitude. It was also shown how a sinusoidal e.m.f. of constant frequency could be derived from the vibrating fork. An attractive exhibit staged by the Signals Research Establishment (Ministry of Supply) demonstrated the synthesis of speech from signals having a low 'information-rate'. Slowly varying parameters specifying the resonant frequencies of the vocal cavity system and the excitation applied to it serve to produce synthetic speech of good intelligibility. A somewhat unusual type of exhibit combined a chemical balance with an electric furnace for the study of change of weight during a prolonged heating process. A two-pen electronic recorder registers the variation of weight during the process. The Royal Aircraft Establishment (Ministry of Supply) showed the operation of a pyroheliometer for use in aircraft, designed to measure the solar radiation incident on the aircraft while in flight. In another exhibit, by the Services Electronics Research Laboratory, it was shown that amorphous selenium, which is opaque in the visible region, transmits radiation in the range from the near infra-red to centimetre wave-lengths. Optical components such as lenses and prisms can be made by simple casting techniques.

The Technical Optics Section of the Imperial College gave a fine series of demonstrations of optical devices. Perhaps the most popular of these was the one dealing with stereoscopic photography and projection. The photographs were taken with a 'Verascope' camera and projected with a pair of Aldis film-strip projectors through 'Polaroid' filters. The three-dimensional picture was viewed with 'Polaroid' spectacles. The projectors were provided with various adjustments for controlling the relative overlap of the two projected pictures as part of a general study of problems in stereoscopic vision. The xerograph, to which reference has already been made, was shown to be a process of photographic image reproduction which depends on a simple application of electrostatics and a photoconduction mechanism in selenium. By this method it is possible to produce either a positive or a negative picture in about a minute, without the usual wet chemical processing. Two stands exhibited what is described as the flying-spot microscope. The object on the microscope stage is scanned by a blue-violet light from a cathode-ray tube and the transmitted light received on a sensitive multiplier photoelectric cell, the output of which is used to modulate a raster on a monitor tube. The latter showed a bright, very much magnified image of the microscopic object.

Permanent magnets in which the pole-pieces are sintered as an integral part of the magnet assembly of 'Alcomax' or 'Alnico' were exhibited, in forms suitable for moving-coil instruments, high-frequency generators, dynamo rotors, etc. By this sintering process it is now possible to obtain a low reluctance path across the junction of the permanent magnet and its soft iron poles. An interesting development in accumulators was shown in which silver (positive) and zinc (negative) form the active plates. Standard production sizes range from 0·5 to 40 amp.-hour capacity having weights ranging from ¾ oz. to 28 oz. The voltage of each cell is 1·5. A new application of the now familiar resistance strain-gauge was exhibited in the form of a submarine pressure meter, the out-of-balance of the bridge being used to indicate pressure, depth under the sea, weight, etc. Direct-writing electrocardiographs were demonstrated using a hot-wire stylus recording on thermo-sensitive paper. This form of recording is almost frictionless at the stylus point, and the hot wire makes a very clear black line as it burns off the ethyl cellulose coating of the recorder paper. An Admiralty research establishment demonstrated a comparator for magnetic materials of low permeability, based on a principle devised by Prof. A. O. Rankine, with a range of permeability of 1·00001–1·0003. This device could give direct indications of the permeability of materials such as distilled water or 'iron-free' copper. A quick-acting sensitive hygrometer is formed from an anodized aluminium wire coated with a thin layer of porous conducting material (for example, 'Aquadag'). The cylindrical condenser thus formed strongly absorbs water vapour (and other vapours), thereby increasing its dielectric constant. The instrument was demonstrated as an atmospheric humidity recorder, and as a detector of moisture in soils and at a number of points in a water-soaked piece of timber. A valuable aid to medical research, of a type mentioned by Prof. Mayneord in his discourse, was a scintillation counter demonstrated under conditions representing typical hospital use. It comprises an eleven-stage photo-multiplier tube, an interchangeable phosphor and a wide-band amplifier. A lead collimator mounted in front of the crystal is used to define the sensitive zone of the instrument. A contamination meter has been designed expressly for civil defence which will measure accurately the gamma-activity of fission products on clothing, etc., in terms of milli-röntgens per hour at a specified distance. The instrument can be used on a table allowing 'suspected' persons to file past the probe, or it can be carried around in a haversack, the probe (containing a Geiger counter) being brought near the suspected areas of contamination. Beta-ray thickness gauges, serving to measure or control the thickness of manufactured materials in the form of strip, foil or sheet, now appear to be in general use in numerous industries manufacturing paper, metal foil, lino, rubber, plastics, etc. A number of exhibits gave demonstrations of this useful device. The use of radioactive tracers in the study of furnace gas flow is now a possibility. By introducing a pulse of radon at the air intake, and scintillation counters to measure its concentration in gas samples taken at various points, valuable information on the furnace behaviour is obtained.

The exhibition of work by apprentices and learners was most impressive. The fine examples of glass-blowing, optical glass work and metal work left one with the feeling that there is plenty of young talent coming along which is quite capable of upholding the high standard of craftsmanship in the British scientific instrument industry. This year, the Silvanus P.

Thompson prize for the most meritorious performance was awarded to R. G. Munro (of the Marconi Wireless Telegraph Co.). Most of the entries were of a very high standard, and the selection of the prize-winner must have presented a very difficult problem for the judges.

As usual, an exhibitors' meeting was held during the exhibition to discuss possible improvements in the organization of future exhibitions. The Council and Exhibition Committee of the Physical Society are to be congratulated on yet another successful exhibition.

A. B. WOOD

# FUNCTION AND LOCATION OF ENZYMES IN CELLS

AT a meeting of the Royal Society on March 12 the subject of "The Function and Location of Enzymes in Cells" was discussed by a number of workers from Great Britain and abroad.

Prof. J. Z. Young (Department of Anatomy, University College, London), in opening the discussion, emphasized that the essence of the problem is to develop methods of high resolution. Much can be done by centrifugation and other methods of separation, but in the end we shall have to depend upon microscopy. Full use of microscopic methods would involve improvement of means of measurement, and a step in this direction might be found in the development of the technique of the flying-spot microscope. He also directed attention to the need for adequate models with which to speak about the organization of processes within the cells, and suggested that perhaps the techniques of information theory might be helpful to biochemists in this respect.

Dr. H. Holter (Carlsberg Laboratory, Copenhagen) described his experiments with the large amœba *Chaos chaos* and discussed the possibility of separation of different phases within its cytoplasm by centrifugation of the living cell. As test enzymes for these investigations, he chose succinic dehydrogenase, dipeptidase and catheptic proteinase, the last an enzyme likely to be difficult to localize because it is especially sensitive to autolytic changes, of which it is itself a mediator.

After cutting centrifuged amœbæ into heavy and light portions, it was found that their dipeptidase content was equal, which means that it is not associated with any centrifugable cell constituent but occurs throughout the cell in the hyaloplasm. On the other hand, the proteinase and succinic dehydrogenase were clearly displaced towards the centrifugal pole and are presumably bound to the mitochondria.

Comparable results were obtained by the technique of centrifugal separation after homogenization, except that the proteinase is liberated by this process from the cell constituent to which it is usually attached. Dr. Holter emphasized that homogenization techniques must, however, always give rise to equivocal results because the hyaloplasm is insoluble in water unless autolysis occurs.

Prof. J. F. Danielli (Department of Zoology, King's College, London) discussed the difficulties involved in the identification of the sites of phosphatase action by cytochemical techniques. He showed that phosphatase is found at sites concerned with active transport, such as the brush border of the proximal convoluted tubules of the kidney, epithelial cells of the small intestine and silk-secreting glands. He went on to develop the thesis that the enzyme is concerned particularly with making energy available for contractile proteins. Thus considerable amounts of phosphatase are found along chromosomes and during new collagen formation. During discussion of this paper, some objections to this hypothesis were raised by Prof. C. D. Darlington and others, who were doubtful whether the association of phosphatases with, for example, nucleoli, could be regarded as evidence of their action upon contractile proteins.

The distribution of enzymic activities of the mitochondria of pea seedlings were then discussed by Dr. D. D. Davies (Department of Botany, University College, Hull), who presented strong evidence that the enzymes responsible for the Krebs cycle in plants are closely associated with the mitochondrial fraction. Each step of the Krebs cycle was demonstrated by chromatographic identification of products in partially inhibited systems.

Dr. S. J. Holt (Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London) described the development of new staining techniques for the intracellular localization of enzymes, beginning with the necessity of finding readily penetrating chromogenic substrates of low molecular weight, but yielding highly insoluble products. The oxidation of indoxyl to indigo has been found to meet most requirements for a chromogenic reaction. The reactions of various substrates derived from indoxyl have been investigated and several found which are very suitable for the revelation of esterases. The chief problems are to obtain a precipitate of negligible granularity and to prevent diffusion effects. Using substrates such as 5-homoindoxyl acetate and 5 : 7-dichloroindoxyl acetate in the presence of suitable oxidizing agents, it is possible to show fine details of the distribution of esterases in motor end-plates and, for example, in the cells of the kidney, liver and pancreas. Methods for phosphatases have also been developed, and extension to other enzymes is well advanced. During discussion of this paper, it was suggested that false localizations might be obtained, due to the activity of oxidizing enzymes producing an indigo at their site of action. Dr. Holt replied that this had been fully investigated and that the same localizations were found in the presence of high concentrations of oxidase inhibitors.

Dr. F. R. Johnson (Department of Anatomy, University of Sheffield) presented slides, prepared by the Gomori technique, of the distribution of alkaline phosphatase in the epithelial cells of the small intestine. He showed that the appearance of the deposit of cobalt sulphide depends on control of the last steps of the technique and is related to the strength and age of the ammonium sulphide solution used. Under suitable conditions, a bilaminar distribution of the enzyme is seen in this tissue and also in kidney proximal convoluted tubules. Prof. H. A. Krebs pointed out that this distribution corresponds to that expected from suggested biochemical mechanisms of transport; but Prof. Danielli was doubtful whether the bilaminar appearance could be regarded as truly reflecting the distribution of the enzyme in the living cell.

Experiments showing that dipeptidase activity is a property of polynucleotides were described by Prof. F. Binkley (Emory University School of Dentistry, Georgia), who has been able to isolate a non-protein fraction from pig kidney which hydrolyses dipeptides such as cysteinylglycine. This activity is not destroyed or decreased by proteolytic enzymes, or in other procedures directed to remove all proteins, or by heating to 80° C., or concentration by evaporation on a water-bath. Further evidence for the absence of protein was obtained by the negative result of standard protein tests and by the fact that the material did not induce antibody formation. Ultra-violet absorption spectra were typical of nucleic acids, and chromatographic analysis showed good correlation with the properties of polynucleotides. Prof. Binkley emphasized that there is no evidence to suggest that any dipeptidase is a protein, and no real surprise should be caused by the discovery that they may be something other than protein. Electrophoretically homogeneous preparations could be prepared by extraction with aqueous acetone and autolysis at 50° C. Subsequent fractional precipitation with ethanol leaves the active component in the supernatant, and a crystalline product can be isolated of extremely high activity compared with that of proteolytic enzymes composed of protein. Some of the difficulties of this interpretation were mentioned, particularly that ribonuclease or snake venom does not destroy the enzyme activity, except at a low *p*H at which activity is rapidly lost even without added enzymes. However, these enzymes do combine in 1 : 1 proportions with the active material and inhibit it. A second difficulty is that commercial nucleic acids are not active as dipeptidases; but they may be made active by a purification procedure. Further experiments have shown that plant viruses have similar peptidase activities and that these are actually enhanced by digestion with proteolytic enzymes.

In the discussion of Prof. Binkley's paper, no convincing difficulties in his interpretation were raised. Prof. J. D. Bernal emphasized the extent to which our views on protein synthesis would be clarified if we could start with the presumption that nucleic acids were themselves proteolytic enzymes.

The localization of enzymes in muscle were discussed by Dr. S. V. Perry (School of Biochemistry, Cambridge), showing in particular that adenosine triphosphate cannot be free in the cell. The myofibrils probably contain bound adenosine triphosphate and the mitochondria an enzyme responsible for splitting it.

Prof. A. Claude (Laboratory of Cytology and Experimental Cancerology, University of Brussels) described his methods for separating cells into fractions of distinct particle size and enzymic activity. He showed that, even with small differences of density, sharp separation is possible by successive centrifugation, though this may be interfered with by agglutination. He compared quantitative determinations of the quantity of glycogen obtained by centrifugation and by chemical separation, and also clearly illustrated the value of this technique as a preparative method by showing gram samples of cell constituents isolated in a short working-time. Prof. Claude then surveyed the morphological features of cells and discussed the fine structure of mitochondria, as revealed by electron microscopy. In conclusion, he pointed out the need for developing more refined centrifugation techniques for the further separation of similar particles, such as mitochondria, into types with different enzymic activities.

Prof. H. A. Krebs (Department of Biochemistry, University of Sheffield) outlined experiments on the distribution of ions and inorganic substances in cells. He emphasized that an understanding of these distributions depends upon our treating the cell as not being in osmotic equilibrium, for the osmotic pressure in a cell may be two or three times that of the blood plasma. The conception that the cell is enveloped by a semi-permeable membrane is not complete because there are many intracellular boundaries; many substances may thus penetrate the cell and yet not gain access to all parts of it. Distribution of sodium ions is maintained by the mechanism of a 'sodium pump' actively removing the ion, and this may occur not only at the cell surface, but also at surfaces within the cell.

Experiments with slices of guinea pig brain and kidney cortex in which the potassium loss and sodium gain were studied were next described by Dr. R. E. Davies (Department of Biochemistry, University of Sheffield). Under proper conditions reversible interchanges can be recorded. The water content of the tissue depends more on its metabolic activity than on the composition of the medium. Thus the turnover number of sodium ions to oxygen consumed was very high (5,000 : 1), and it is necessary to postulate an energy-linking system between entry to and escape from the cell. Treatment with dinitrophenol unlinks the process of transport from its energy sources and allows accumulation of sodium within the cell. The whole of the sodium and potassium content of a cell was found to be able to exchange in a very short time. Dr. Davies then presented evidence that these activities are controlled by enzymes located in the mitochondria. Fractions consisting mainly of mitochondria are thus able to concentrate ions and pump out water.

In closing the discussion, Prof. Young thanked the contributors for the various original observations reported during the day; he directed attention to the fact that the only mention of a new model was Prof. Krebs's comparison of the cell with a leaky ship kept afloat by pumps.

# SAMPLE TABLES FOR THE 1951 CENSUS OF GREAT BRITAIN

In the past, the General Register Office has often been severely criticized for its delay in the publication of the results of the decennial census of population. The critics often ignored the fact that the professional staff of the Office was very small, and that they had to cope with the routine work of the Office in addition to the census. It is therefore most creditable to the Office that a summary of the main results of the 1951 census came into the hands of the public within nineteen months of the date of enumeration*.

This was only made possible by the decision—for the first time in the history of censuses in Great Britain—to make a preliminary analysis of a sample of 1 per cent of the census schedules. Sampling had an additional advantage—tabulations which would have been prohibitively expensive and complicated in a full census were quite feasible for a sample. A sample of census schedules is also likely to be more accurate than an *ad hoc* inquiry: the completion of the schedule is compulsory, and sample selection can therefore be strictly controlled. The problem of non-response is minimized, and there is probably more goodwill among the general public towards the census. The sample itself will be so large that sampling error will be negligible, and it is therefore to be hoped that the sampling procedure will be continued in the future. Although the sampling error is negligible, it is unfortunate that it is not discussed at greater length in the introductory pages. Those responsible for the publication of the report surely owe a duty to the public to explain their working methods fully, rather than treat them as esoteric mysteries. This is a small point; but there has recently been a general tendency on the part of those at the Office to explain their working methods in such general terms that it is not possible to follow their work in detail, so that criticism is made unduly difficult. (For example, the number of 'schedules' drawn in the sample as distinct from the number of 'persons' is nowhere given.) A second innovation must be gratefully mentioned. For the first time for a hundred years, the results for Great Britain are given in a single volume. It is to be hoped that the co-operation between the two registrars-general of England and Wales and of Scotland will continue, and that the national tables of the full census will also be given for Great Britain as a whole, as well as for the two constituent countries. It has been one of the minor irritations of persons working on British population figures to have to work with two different fat volumes, and occasionally to discover irritating minor differences in the definition of terms.

---

* General Register Office and General Registry Office Scotland. Census 1951, Great Britain: One Per Cent Sample Tables. Pp. 367. (London. H.M.S.O., 1952.) Part 1, 17*s.* 6*d.*; Part 2, £2.

The sample tables in the two parts are numbered consecutively, so that the report may be regarded as a single whole. It is divided into different sections, and it would be invidious as well as presuming to try to deal with the results and their significance in a short article. I shall therefore content myself with describing the tabulations, indicating the innovations and commenting on some of the methods.

One of the main functions of the census is to give detailed statistics for local areas. In a 1 per cent sample the details must necessarily be less extensive than in a full enumeration, and the local tabulations are confined to the counties and larger towns. There is one welcome innovation, however: the provision of separate tables for the seven large conurbations centred on London, Birmingham, Manchester, Liverpool, Leeds, Newcastle and Glasgow.

*Ages, Marital Condition, Occupations and Industries.* These subjects are, of course, the main concern of the census-taker. The treatment follows conventional lines, but there are some minor innovations. The occupations are divided into thirteen 'socio-economic groups' in addition to the conventional five so-called 'social classes'. Any attempt at social classification which is based on occupations only must of necessity be rough, and can at best only approximate to what the sociologist understands by 'social class'; but given these limitations, a division into thirteen groups will, of course, be much more useful than one which makes use of five groups only, particularly when housing and fertility differentials are studied.

From the tables it is possible to obtain information about the structure of the population by sex, age, marital status, occupation and industry, and about some of these factors in combination. One can study the age structure of the labour force, the number of women in different industries, the extent of the employment of married women, and similar topics.

*Housing and Structure of Private Households.* The census defines a private household as a "single person living alone or a group of individuals voluntarily living together under a single menage in the sense of sharing the same living room or eating at the same table; boarders and domestic servants are included in the household with which they are enumerated as also are visitors when such are present. But a lodger or group of lodgers having or sharing separate accommodation to themselves should have been enumerated on separate schedules and are thus treated as separate private households, distinct from the main occupying household of the dwelling, whether or not they rely on the latter for incidental service in the matter of room cleaning, food preparation, etc.".

It will be seen that the definition of a private household is necessarily a little vague, and that ambiguities are bound to arise. In the case of lodgers there is an almost infinite gradation between the boarder who lives *en famille*, on one hand, and the lodger who merely rents a room to sleep in and has no dealings with the rest of the household, on the other; and in marginal cases it is difficult to ensure uniform treatment. Moreover, there is the problem of visitors. It is not very easy administratively to allocate visitors who are away from their homes back to the area of their usual residence. It seems likely *a priori* that members of small households are more likely to be mobile than those from larger ones, so that errors do not necessarily cancel out. It is also evident that the term 'private household' is not synonymous with the term 'family'. This confusion has been partly caused by the use of the latter word in previous censuses.

The tables show the total number of households by size and by number of rooms occupied, distinguishing in general those households which have to share a dwelling. Crowding indices can be calculated from these data. It should, however, be borne in mind that the number of rooms in the dwelling is obtained by the enumerator in the course of a hurried visit. Though substantial inaccuracies are unlikely, these figures are probably of a lower reliability than the rest of the census data.

The foregoing remarks also apply to a new feature. In 1951 enumerators were instructed to inquire whether the household had the exclusive use of piped water, cooking stove, kitchen sink, water closet and fixed bath, or whether any or all of these amenities were shared with another household. The tabulated answers make it possible to compare housing conditions in different parts of the country.

The second volume begins with tables showing information on household structure. The households are classified by the number of earners and the number of children that they contain; but it is the section next following which is of particular interest. Here an attempt is made to study in greater detail the structure and composition of private households, and, for this purpose, visitors have been excluded. Households are divided into those containing 'primary family units' only—that is, consisting merely of the head of the household, his or her spouse, children, ancestors and unmarried sibs of the head, and resident domestic servants. Such households form 86 per cent of the total contained in the sample. In the remaining 'composite' households, the members not belonging to a primary family unit have been further analysed into 'family nuclei' consisting of married couples or lone parents with their children. Composite households containing such nuclei were regarded as less stable than other composite households, as it was believed that they would in most cases desire separate accommodation of their own. Their number and distribution would give one index of the amount of involuntary 'doubling-up' that exists. It was found that roughly a half of all composite households contained family nuclei, the large majority of these consisting of married children of the head or his spouse.

This tabulation will not be repeated for the full census. It is therefore regrettable that the data are only broken down by geographical region and that no attempt has been made to obtain information regarding household structure by occupation or social class. Such information has not previously been available, and its publication might throw some light on the nature of the housing problem which we are facing.

*Education.* One of the new questions included in the census related to the age at which full-time educational instruction had ceased. For some incomprehensible reason, the question was confined to males and occupied females, so that no information is available about the education of housewives (whom the census authorities still regard as 'unoccupied'). Moreover, the figures are particularly difficult to interpret at present, as the education of many persons was interrupted by the Second World War and continued after demobilization, so that the proportion whose education ends comparatively late may well be abnormally high. More valuable results may be obtained at the next census, when the question should, however, be re-phrased, as the age at which education ends is only one of the factors influencing what might loosely be described as 'education status'.

*Fertility of Marriage.* In the present census questions relating to the fertility of marriage have been asked for the first time since 1911. All married women under the age of fifty were required to state the date of their present marriage, the total number of children born alive to them, and whether they had given birth to a live child in the year preceding the census. The information is tabulated in a special section of sixty pages, and the tables are well set out. The limitation of the questions to women under the age of fifty is, however, utterly incomprehensible and most deplorable. It means that no comparisons can be made with the fertility experience of older women who bore the greater part of their children in the early nineteen-twenties. It is true that the sample census of the Royal Commission on Population taken in 1946 will remedy some of the deficiency, but it is by no means certain that the material will be comparable.

Information is made available about the distribution of married women by marriage duration, age, age at marriage and total number of children. The figures for social class and socio-economic group are analysed, and the women who bore a child in the year preceding the census are separately distinguished. It is thus possible to obtain data on differential fertility without having to marry vital registration and census statistics, in which occupational and other definitions may sometimes differ, thus causing minor incomparabilities.

*Minor Tabulations.* Among other information presented there is a table dealing with non-private households, information regarding birthplace and nationality, and statistics on the Welsh- and Gaelic-speaking population.

Enough has been said to indicate the wealth of material available in the new publication. No full census has been taken in Britain since 1931, and the information is therefore all the more welcome. The sample tables will probably contain sufficient detail for most purposes. The full evaluation of the data will take time, but they promise to throw light on some social problems about which hitherto relatively little was known.

E. GREBENIK

# OBITUARIES

## Sir Francis Knowles, Bart.

SIR FRANCIS HOWE SEYMOUR KNOWLES, fifth baronet, who died at Oxford on April 4, at the age of sixty-seven, made notable contributions to two branches of the complex discipline of anthropology. Like many other anthropologists, he began his studies in a different field of knowledge, for he read law at Oriel College, Oxford. He then took the diploma in anthropology at the first examination held in Oxford (1908), and afterwards the degree of B.Sc. During 1909–12 he taught physical anthropology under Prof. Arthur Thomson, helping to place the subject on a firm scientific foundation. During that period he catalogued and measured two large collections of skulls; he also collaborated with Sir Arthur Keith in a study of teeth of palæolithic man from Jersey, and with Prof. W. J. Sollas in an examination of the Aurignacian skeleton from Paviland Cave, Gower.

He left Oxford to undertake field-work among the Iroquois in Ontario. In 1914 he was appointed physical anthropologist to the Canadian Government, a post which he held for five years. His work on the skeletal material from the Roebuck prehistoric village site, "The Physical Anthropology of the Roebuck Iroquois", was published by the National Museum of Canada. A severe attack of typhoid, contracted in the field, left his health permanently impaired, and brought his career as a physical anthropologist to a premature end.

Returning to Oxford, Knowles took up the study of a subject in which he had long been interested, namely, the techniques used by ancient and modern Stone Age peoples in the manufacture of their tools and weapons. Using only the materials and tools known to have been available to prehistoric man, he practised patiently until he had acquired a skill comparable to that of the best craftsmen of the past. In this way began his long association with the Pitt Rivers Museum, Oxford, where he studied, and added considerably to, the prehistoric collections, arranged exhibition cases showing the variety of techniques employed by stone-workers from ancient to modern times, and held practical classes whereby his pupils obtained an insight into the difficulties overcome by prehistoric man. One of his most important discoveries was described in "The Manufacture of a Flint Arrow-head by Quartzite Hammer-stone", published as the first of the Museum's "Occasional Papers on Technology". Shortly before his death, he completed "Stone-Worker's Progress" for the same series.

Knowles took nothing for granted, but taught and published only what he had learned and verified by personal observation and experiment, thus giving lasting value to his work. His scholarship, his enthusiasm for his subject, and the selfless devotion with which he applied himself even to the routine tasks inseparable from it, were greatly admired by his colleagues, who will long remember him with respect and affection.

B. M. BLACKWOOD

## Mr. W. M. Jones

The death occurred on March 15 of W. M. Jones, director of the Oceanographic Observatory of the Department of Scientific and Industrial Research, New Zealand. Born in Papakura in 1893, he graduated in 1914 with honours in mathematics. He was the New Zealand Rhodes Scholar of that year and took honours in physics at Balliol, Oxford. He served in the First World War in the Royal Field Artillery and N.Z. Engineers, and, after a few more years at Oxford as demonstrator in the electricity laboratory, returned to New Zealand.

His early magnetic, seismological and other geophysical work in New Zealand foreshadowed many of the discoveries which are of greatest interest to-day, and did much to establish the usefulness of scientific exploration. In 1950 he was given the task of developing oceanographical research in New Zealand, and has done much to advance the systematic study of the waters which influence its life, climate and fisheries. Being mainly interested in the applications of mathematics and physics, he has done useful research on waves, the relation between waves and microseisms, and the electromagnetic effects of tidal streams.

Jones had a wide interest in science apart from his own subjects, and an extensive knowledge of New Zealand. He was a very amusing travelling companion and always found the most interesting people to talk to and the most interesting things to do. His great fund of anecdotes about his early geophysical exploration showed a wealth of good feeling and love for his country. In his younger days he was a representative player of hockey and tennis both in Auckland and in Great Britain.

Jones's work was well known in Britain and the United States, as well as in New Zealand, and he will be greatly missed. G. E. R. Deacon

# NEWS and VIEWS

## Royal Institution:
### Sir Lawrence Bragg, O.B.E., F.R.S.

After the annual meeting of the members of the Royal Institution held on May 1, Lord Brabazon of Tara (president) announced that the managers had appointed Sir Lawrence Bragg to the office of Fullerian professor of chemistry, resident professor and director of the Institution's laboratories. He will take up the duties of the Fullerian professorship immediately and the laboratory and resident duties on January 1, 1954. Sir Lawrence has been Cavendish professor of experimental physics in the University of Cambridge since 1938. Previous to this he had been director of the National Physical Laboratory, and he had also been Langworthy professor of physics, University of Manchester. He brings great academic distinction to the Royal Institution, and is worthy to stand in the place of Humphry Davy, Faraday, and the many famous scientists who succeeded them. Sir Lawrence had a brilliant career as a student and Research Fellow at Trinity College, Cambridge. In 1915, at the early age of twenty-five, he was awarded a Nobel Prize for Physics for his work on X-rays and crystal structure with his father, the late Sir William Bragg, who is remembered with affection by all connected with the Royal Institution as not only one of the most distinguished holders of the offices his son now receives, but also one of the best loved. For his many contributions to physical science Sir Lawrence has been awarded the Hughes and Royal Medals of the Royal Society, and honorary degrees and distinctions from many universities and scientific societies at home and abroad. He will bring to the Royal Institution not only an unrivalled record of scientific achievement and experience, but also those personal attributes of friendship and sympathy so characteristic of his father.

### Other Officers

The following have been elected officers of the Royal Institution: *President:* Lord Brabazon of Tara; *Treasurer:* Dr. L. H. Lampitt; *Secretary:* Mr. S. Hobson; *Managers:* Mr. L. V. Chilton, Dr. A. Clow, Mr. E. R. Davies, Mr. F. P. Dunn, Dr. A. G. Gaydon, Dr. R. E. Gibbs, Mr. A. C. Hartley, Mrs. H. K. Hawkes, Mr. L. B. W. Jolley, Dr. L. A. Jordan, Dr. H. Lowery, Dr. A. C. Menzies, Dr. J. H. Schulman, Mr. P. H. Schwarzschild, Dr. S. Whitehead; *Visitors:* Mr. H. E. Baker, Mr. F. G. Brown, Dr. H. K. Cameron, Mr. A. D. R. Caroe, Mr. J. F. Coales, Dr. H. Heywood, Wing Commander G. e. Hughes, Dr. A. R. Kagan, Mr. M. M. Melinsky, Mr. E. B. Moss, Mr. F. Y. Poynton, the Hon. Philip Samuel, Mr. W. E. Schall, Dr. L. Simons, Dr. P. C. Spensley.

## Fuel Technology at Sheffield:
### Prof. R. J. Sarjant, O.B.E.

The University of Sheffield—and indeed the community at large—owes much to Prof. R. J. Sarjant, who retires from the chair of fuel technology at the end of the academic year. Educated at the Royal Masonic School, Bushey, he graduated in chemistry at the Royal College of Science, London, afterwards receiving postgraduate training there. In 1918 his appointment as fuel officer to the research department of Hadfields, Ltd., was the beginning of more than a quarter of a century's experience of steelworks problems, including those concerned with refractory materials and metallurgical engineering. With Sir Robert Hadfield he published a number of papers on the use of solid, liquid and gaseous fuels, gas producer practice, alloy steels for furnaces and chemical engineering; and in 1924 he gave the first course of lectures on furnace heating at the University of Sheffield, the following year publishing in a book the results of his pioneer work. In 1937 he was appointed a local director of Hadfields and head of its research department, relinquishing this position at the end of the Second World War on his appointment to the Sheffield chair; this chair had been vacant since R. V. Wheeler's death in 1938, and in returning to academic life after a successful industrial career Prof. Sarjant recognized the opportunity for wider service and the need for great expansion of university training in fuel technology. He has always been keenly interested in university education in applied science, and set about extending his department with characteristic enthusiasm. Shortly after his appointment, he visited American universities and research organizations, and two years later was invited to lecture in Spain. He has been associated with many research committees on fuel and allied problems and was awarded the O.B.E. for his services to the wartime Fuel Efficiency Committee of the Ministry of Fuel and Power. Prof. Sarjant was a vice-president of the Institute of Fuel during 1949–51 and in 1950 was awarded its highest honour, the Melchett Medal, choosing "Ignipotence" as the subject of his address. In this address he described some of the researches in his department, where incidentally there is now a record number of postgraduate students; the researches include work on coal chemistry, the reactivity, properties and production of metallurgical coke, heat transfer, furnace design, smoke repression in metallurgical operations, and gasification of low-grade fuels.

### Mr. M. W. Thring

MR. M. W. THRING, who succeeds Prof. Sarjant, was educated at Malvern College and Trinity College, Cambridge, graduating with first-class honours in Part 1 of the Mathematical Tripos and in Part 2 of the Natural Sciences Tripos. In 1937 he joined the staff of the newly formed British Coal Utilization Research Association, becoming head of the Combustion Research Laboratory in 1944. Experimental and theoretical work on the velocities and temperature drop in producer gas mains led to the award of the Student Medal of the Institute of Fuel in 1938. Among his war-time studies were the design of portable gas producers and the development of the down-jet system of combustion in fuel beds; these investigations culminated in a major study of port designs in open-hearth furnaces, carried out in 1944 in collaboration with Dr. J. H. Chesters, of the United Steel Companies, Ltd., and in 1949 Mr. Thring was awarded the Sir Robert Hadfield Medal of the Iron and Steel Institute for studies on open-hearth furnaces. In 1946 he took up a new post as head of the Physics Department of the British Iron and Steel Research Association, later being appointed superintendent and, recently, assistant director of the Association. In 1949 he took part in the early discussions leading to the formation of the International Committee for Research on Luminous Flame Radiation, and two years later became general superintendent of its researches. Mr. Thring is the author of a book on "The Science of Flames and Furnaces" and of many papers on fuel subjects, and he has made valuable contributions to the theoretical understanding of radiation during combustion and of the mechanism of combustion in turbulent jet flames.

### Atomic Energy Research in Britain

REPLYING to a question in the House of Commons on April 28, Sir Winston Churchill stated that the Government has set up a committee, consisting of Lord Waverley (chairman), Sir Wallace Akers and Sir John Woods, with the following terms of reference: "To devise a plan for transferring responsibility for atomic energy from the Ministry of Supply to a non-departmental organization and to work out the most suitable form for the new organization, due regard being paid to any constitutional and financial implications". He remarked that considerable strides have been made in the development of methods of using atomic energy for industrial purposes, and these aspects are now coming very much to the fore. A non-departmental organization is considered by the Government to be necessary to secure rapid and economical development, for both military and industrial purposes, and the committee has the task of visiting the various establishments concerned with the view of devising a form of organization to meet the very special needs of the case. Overall policy must remain firmly in the hands of the Government, and methods of financial control will have to be devised since in the foreseeable future the considerable cost will fall on public funds. The rights and interests of existing staff in atomic energy establishments will be fully respected. It will be recalled that in July 1951, Lord Cherwell, speaking in the House of Lords, asked for the transfer of atomic energy development to some such non-departmental agency.

### Atomic Energy Establishments in Britain

ON May 4, Mr. Duncan Sandys, Minister of Supply, gave some information in the House of Commons about the work of atomic energy establishments in Great Britain. He said that Harwell is responsible for fundamental research into nuclear physics and atomic energy, and provides basic scientific information to the other establishments. The radio-chemical centre at Amersham is an offshoot of Harwell. It deals with the preparation of radioactive substances such as radium, radon, and radioactive isotopes produced in the atomic piles, and these are used for medical, scientific and industrial purposes. The production of fissile material is directed from headquarters at Risley, near Warrington, where the design and planning offices are situated. A factory at Springfields, near Preston, produces pure uranium from uranium concentrates; another, at Windscale, in Cumberland, produces plutonium from uranium by means of atomic piles; and a third, at Capenhurst, in Cheshire, has a gaseous diffusion plant for separating uranium-235 from the more abundant isotope uranium-238, producing a fissile material which can be used as an alternative to plutonium. Research work on atomic weapons is carried on at Aldermaston, in Berkshire, and its out-stations at Woolwich and Fort Halstead.

### Effects of Toxic Substances on Wild Life

A WRITTEN reply by the Minister of Agriculture, Sir Thomas Dugdale, given in the House of Commons on May 4, stated that the working party considering precautionary measures in the agricultural use of toxic substances has been reconstituted under the chairmanship of Prof. S. Zuckerman and will now consider the effects of such substances on wild life in general. It will include representatives of the agricultural departments, the Agricultural Research Council, the Agricultural Improvement Council, the Nature Conservancy, the fisheries departments, and the Medical Research Council. Its terms of reference will be: "To investigate the possible risks to the natural flora and fauna of the countryside from the use in agriculture of toxic substances, including the possible harmful effects for agriculture and fisheries, and to make recommendations".

### Exhibition in the Science Museum, London, of Historic Books on Machines

THE second of a series of special exhibitions of historic books relative to science and technology was opened at the Science Museum, London, on May 1 and will remain on view to the public, free of charge, until August 30 (weekdays, 10 a.m.–6 p.m.; Sundays, 2.30–6 p.m.). The exhibition deals with machinery and traces the development of machines from classical times up to the period of the Industrial Revolution in the eighteenth century. Although some of the very early machines were exceedingly crude in appearance, they often embodied fundamental principles which were taken up in later times when materials and methods of construction were more developed. The progress of machines increased during the Renaissance, and more interest in them was stimulated about 1440 when movable-type printing was invented; it was then possible for books to be produced more cheaply and in larger numbers. The knowledge spread from Alexandria, to Greece, Italy, France, Germany and Britain, and by the seventeenth century there was much scientific activity, both theoretical and practical, which hastened their progress; with the development in Great Britain of the steam-engine during the eighteenth century, far-reaching economic and social changes occurred throughout Europe. The parts which great philosophers and pioneers, such as Heron of Alexandria, Archimedes, Cardan, Agricola, Gilbert, Galilei, Boyle, the Marquis of Worcester, von Guericke, Morland, Papin, Savery, Pascal and Faraday, played in the development of machinery is illustrated by many of the books. In general, the exhibition should appeal not only to those with a developed appreciation of machinery but also to all who, though they may have a slight knowledge of the subject, are interested in the materialistic progress of civilization.

### Agricultural Census in Iraq

Many important facts concerning agriculture in Iraq are being revealed for the first time by an agricultural and livestock census which was taken during the second half of 1952 under the direction of the government statistician, Dr. K. G. Fenelon, who was formerly director of statistics and intelligence at the British Ministry of Food. Every effort is being made to publish the data as rapidly as possible, and already reports are available for three out of the fourteen provinces (*liwas*) into which the country is divided for administrative purposes. These reports cover the Provinces of Baghdad, Basra and Amarah and show in considerable detail the great diversity of conditions under which farming is carried out in the country and the great variety of crops which can be grown. In Amarah Province, for example, the average size of the 483 farms in the area is 3,530 acres, there being a hundred farms of more than three thousand acres each, among which seven are more than thirty thousand acres each. In Baghdad Province, the 3,821 holdings average 240 acres, while in Basra the 18,013 farms average only 15 acres each, with some 11,000 farms less than 2½ acres in extent. The small size of farms in Basra is partially explained by the prevalence of date palm cultivation, which accounts for nearly one-third of the total area of the holdings. In Baghdad Province, there are more than three million fruit trees such as orange, apple, pomegranate, lemon and apricot, compared with two hundred thousand in Basra and thirty-five thousand in Amarah Provinces. The main field crops in the three Provinces are barley, wheat, rice and maize.

Considerable differences were found in the amount of labour engaged on the holdings. In Amarah there is one person for 25½ acres, in Baghdad one for 8 acres and in Basra Province one for 3½ acres. Livestock are somewhat more densely settled on the land, there being one head of livestock for every 3 acres in Amarah Province, 2·7 acres in Basra Province and 2 acres in Baghdad Province. In addition to the livestock on the farms, numerous other animals are maintained by 'stall feeding' or by pasturing on waste lands. In Baghdad Centre many cows, buffaloes and sheep are stall-fed, while in Basra Province many flocks were found pastured on waste lands, which varied in size from a few animals kept by individual families to immense herds of sheep, horses and camels owned by nomadic tribes, some of which roamed between Iraq, Kuwait and Saudi Arabia. Mechanical power is used on about eight hundred farms in the three provinces, but nearly all of these were situated in Baghdad Province. There are, however, eighteen thousand farms, mainly in Basra Province, which rely on human labour alone without any assistance from either animals or machines.

### Archæological Excavations near Behshahr, Iran

Three interesting articles on the excavations in the Hotu Cave, Iran, are contained in a recent issue of the *Proceedings of the American Philosophical Society* (96, No. 3; June 1952). The first of these, by C. S. Coon, deals with the site itself near Behshahr in the Caspian Sea region. Excavations were undertaken, and a brief account of them is given. Louis B. Dupree next describes the Pleistocene artefacts found. These consist both of bone and stone tools. There is plenty of material for study; but the industries contain few typical tools which can be linked up with finds made elsewhere. Further work at the site will be needed before any definite conclusions can be drawn. J. L. Angel in a third article describes the human skeletal remains from the Cave. Judging from the illustrations, the skull and jaw have been excellently preserved. Once again, it would seem that the skeletal remains do not fall into any well-known category. Obviously the excavators have discovered an interesting early occupation cave-site in an interesting region, and it is to be hoped that further explorations at Hotu and neighbouring sites will enable the authors to determine more accurately the age and relationships of the industries present.

### *Bulletin of the Italian Society of Geophysics and Meteorology*

The formation of the Italian Society of Geophysics and Meteorology in 1952 (see *Nature*, 170, 144; 1952) has now been followed by the first number of the Society's *Bulletin* (*Bol. Soc. Ital. Geof. Met.*, 1, No. 1; 1953. From the Society at Via Balbi 5, Genova; 3000 lire or 5 dollars a year). The contents of this first number include a paper on the exploration of the ionosphere over the Antarctic by an Argentine expedition, reviews of the present state of knowledge of cloud physics and artificial precipitation and of the relations between the electric field in the atmosphere and the humidity and quantity of pollution, a note on the causes of earthquakes, and reports of scientific conferences and news of recent researches on a world-wide scale. The cover carries a superb photograph of a waterspout off the Italian coast. It is not planned to publish large original papers by Italian geophysicists in this periodical. Such papers will continue to be published in *Geofisica pura e applicata*.

### Press Guide to British Chemicals and their Manufacturers

The Association of British Chemical Manufacturers has recently published a small book entitled "Press Guide to British Chemicals and their Manufacturers" (pp. 76; March 1953) and two thousand copies have been issued in the first instance to the national, provincial and technical press (including scientific correspondents, editors of learned journals, etc.). The first twenty-two pages list the names and addresses of 126 chemical manufacturers, with the name and telephone number of an individual (often two names are given) who is authorized to supply information. A similar short section of two pages follows in which thirteen chemical trade associations are listed, dealing with special sections of the chemical and closely allied industries. The third section, consisting of seven pages, is an alphabetical list of chemical products, each one being indexed to at least one code number that represents the firm handling the product. Finally comes the fourth section, forty-five pages long, which contains a list of proprietary and trade names, and opposite each entry is the chemical name and the firm owning the copyright. Inquiries relating to this booklet should be addressed to the Association at 166 Piccadilly, London, W.1.

## Announcements

Prof. F. J. M. Stratton, formerly professor of astrophysics and director of the Solar Physics Observatory in the University of Cambridge, has been elected president of the Society for Psychical Research in succession to Dr. Gilbert Murray.

The following appointments have been made in the University of London: Dr. C. B. Allsopp, reader in physics at Guy's Hospital Medical School, to the University chair of physics applied to medicine, tenable at the School; Dr. E. M. Crook, senior lecturer in the Department of Biochemistry at University College, London, to the University readership in biochemistry, tenable at the College.

The second British Instrument Industries' Exhibition will be held in the National Hall, Olympia, London, during June 30–July 11. The Exhibition will cover all spheres of instrumentation in industry, medicine, research and education. The organizers of the Exhibition are F. W. Bridges and Sons, Ltd., Grand Buildings, Trafalgar Square, London, W.C.2.

The North-Western Branch of the Institution of Electronics will be holding its eighth annual exhibition of electronic devices at the College of Technology, Sackville Street, Manchester, during July 15 (12–10 p.m.), July 16–17 (10 a.m.–10 p.m.), July 18 (10 a.m.–7 p.m.), July 20 (10 a.m.–10 p.m.) and July 21 (10 a.m.–9 p.m.). In addition to the usual commercial section of the exhibition, there will be a scientific and industrial research section, incorporating exhibits from research associations and the universities. Copies of the exhibition catalogue (1s. 6d. post free) will be available early in July. Admission tickets (available after June 1) and further information can be obtained from the secretary, W. Birtwistle, 17 Blackwater Street, Rochdale, Lancs.

A conference on nuclear physics at intermediate energies will be held by the University of Pittsburgh during June 4–6, the provisional list of topics to be covered being beta-decay, nuclear reactions and scattering at intermediate energies, energy levels of light nuclei, and photo-induced reactions. Further information can be obtained from Dr. E. Gerjuoy, Department of Physics, University, Pittsburgh 13, Pa.

Last year, a meeting for Nobel prize-winners in chemistry was held at Lindau, Bavaria (see *Nature*, 169, 868; 1952), and was attended by nearly a thousand visitors. A similar meeting is being arranged this year, at which Nobel prize-winners in physics will be asked to give addresses; it will be held during June 29–July 2.

A postgraduate summer school in optical crystallographic methods, organized by the Department of Inorganic and Physical Chemistry of the University of Leeds in association with the Department of Adult Education and Extra-Mural Studies, will be held in the University during August 31–September 11. The course, which will be similar to those held in 1951 and 1952, will provide basic training in the theory and the practical use of the polarizing microscope for the study of crystals and other birefringent materials, and in the applications of the instrument in various branches of science and technology. The general aspects will be dealt with during the first week, and during the second students will specialize in their particular group; for example, chemical, mineralogical or biological. The fee for the course is 15 guineas. Residence is available at a cost of £10. Application forms (to be completed by May 11) and further information can be obtained from the Secretary, Department of Adult Education and Extra-Mural Studies, The University, Leeds 2.

The report on research at the Royal Technical College, Glasgow, during the session 1951–52 (pp. 36; 1952), gives a brief summary of research work in progress in the various departments, and to each account there is appended a list of the more important publications by members of the staff of the particular department during the year, with the titles of theses approved for higher degrees and particulars of reports prepared. The report replaces the former *Journal of the Royal Technical College*, publication of which has now ceased.

The Library of the United States Congress and Princeton University are sponsoring a conference on "Islamic Civilization and Culture", to be held in Princeton, N.J., during September 8–17, and in Washington, D.C., September 17–19. Thirty eminent Muslim scholars and intellectual leaders from countries of the Middle East and Asia have been invited to participate, and there will be a similar number of American delegates. The conference will be concerned with three aspects of the subject: classical elements in Islamic culture; Islamic law and society; and intellectual and spiritual movements in Islam to-day. Dr. Bayard Dodge, president emeritus of the American University, Beirut, Lebanon, is the executive director of the conference.

A list, under their current titles, of periodicals received in the Technical Library, Ratcliff Place, has been issued by the Birmingham Public Libraries (pp. 20; 1953). The list shows the Library's holding of each periodical, irrespective of any change of title, but does not include 1,250 periodicals and transactions of societies taken in the General Reference Library or the five hundred received at the Commercial and Patents Library. Periodicals with distinctive titles are entered alphabetically, neglecting the article, but other periodicals published by corporate bodies are entered under the names of the corporate bodies.

Erratum. In the list of awards of Commonwealth Fund Fellowships in *Nature* of May 2, p. 776, for "J. M. Williams" read "R. L. Williams".

# SOCIAL POLICY AND THE SOCIAL SCIENCES

UNDER the broad, general title of "Social Policy and the Social Sciences", the recently formed British Sociological Association arranged its first conference, held during March 27–29 at Queen Elizabeth College, London. The opening address was given by Dr. Gunnar Myrdal, the executive secretary of the Economic Commission for Europe, who dealt with the relation between social theory and social policy. The whole of March 28 was devoted to group discussions, in which the conference was divided into three sections, meeting simultaneously; and on the following morning Prof. T. H. Marshall, after receiving verbal reports from the chairmen of the three groups, summed up on the work of the conference.

The first group began its discussions by considering what contribution social scientists could make to their main subject, namely, health. Dr. J. N. Morris, in introducing his paper on "Changing Needs", asked the pertinent question what, in our way of living, is leading to so much inefficiency and disease. Very little research, he said, is being carried out on the running of the health services, either to provide us with basic knowledge or even to enable us to judge how good the services are. More study is required if we are to know how far we are preserving freedom and the essential ideals of democracy. He suggested that social scientists might well collaborate with the medical profession in acquiring fundamental knowledge that would help us to deal effectively with such matters as smoke pollution, the defects of the catering industry, and the building industry. Many of these problems are social rather than medical; but teamwork is needed.

Prof. Ferguson Rodger, in a useful paper, took up the theme of changing needs from the angle of the psychiatric services. He showed how the scope of psychiatry has expanded rapidly from the concept of mere custody to a concerted and intelligent plan designed to care for the far greater numbers who are incapacitated by neurosis. In spite of this, half the hospital beds in Great Britain are devoted to major mental illness, and it is natural that we should still be hospital-minded and only half aware of the great advances in non-institutional psychiatric treatment. Prof. Rodger cited, for example, the therapeutic and economic value of hostels and day hospitals; the development of the latter means that twice as many patients can be treated in the same space, through the saving in beds and other night furniture.

As the discussion went on, it became clear that the emphasis was shifting from the consideration of medical needs as such to the *terra incognita* between medical and social science. Dr. M. I. Roemer, for example, asked how social science could help in the transfer of new ideas from one culture to another. This means that it should address itself to study of the best time for their absorption, as well as the rate at which new findings in medical care could be digested. Dr. J. H. F. Brotherston carried the discussion further by considering, in a thoughtful paper, how medical education could be helped to give the student a deeper knowledge of the springs of human behaviour. Much could be done, he felt, by showing the student the real practice of both medicine and social work in the homes of the people: "The medical student emerges from training with a well-developed scientific approach to disease processes. At the same time he may be as ignorant as the next man when it comes to understanding his patient as a person whose social situation is of the greatest importance in determining his reaction to ill-health. His scientific training may increase rather than diminish his difficulties in this direction".

In this way the issue of the practical contribution of social work to medical practice is revealed, and its value is generally agreed. A more fundamental question, however, was uncovered, so to speak, by Dr. Brotherston's plea for integration. What is social science, and how far can its practical applications be regarded as the core of the subject? Social science is concerned with human behaviour, but honour is not satisfied merely by its handing over a technique to medicine, even if it bears the pleonastic title of 'social medicine'. If social science and medicine are to work happily together, then each needs confidence in its own techniques, and there must be an agreed common basis of understanding. It may well be that the medical man needs the help of social science in therapy, in preventive action—such as the limitation of neurosis—and, above all, in framing policy through the study of priorities in medical care. The fundamentals of social science were again considered, by Prof. M. Ginsberg, in his closing commentary on the conference. While recognizing the great value of the conference in bringing together workers in so many different fields, he felt that the meeting as a whole suffered from the vagueness of its title, especially as it concealed a lack of real knowledge of the terms social science and social policy. He argued that a good deal of so-called social research is not research in any accepted sense of the term; much of it is plain common sense mixed with a little elementary physiology and psychology. There is a profound difference between fundamental and applied theory, and therefore the function of social science proper is to find out the principles themselves. Social psychology, for example, is in danger of being overwhelmed with new techniques, as in the study of public opinion. The theoretical side is not being investigated at all, as, for example, the theory of public suggestibility as a basis for propaganda. The study of the techniques of propaganda and public attitudes do not advance the theory at all. Similarly, in relation to values, Prof. Ginsberg pointed out the confusion between fundamental studies and the operational research which consists in trying to find out what people want. This is a relatively simple matter, he said; but when one begins to criticize what people want, that is where values come in.

The group dealing with health further considered the problem of co-ordination and integration of the tripartite services under legislation for the National Health Service in Great Britain. In many respects our lack of knowledge of how the Service works is a serious matter; and, as Prof. R. M. Titmuss pointed out in his paper, there is a great deal of confusion not only about the role of the social services but also about the theoretical framework within which these services can be appraised as an integral part of the total performance of the social system.

The papers belonging to the second section, 'Design and Planning", ranged over a very wide field, from the broad implications of the Town and Country Planning Acts to the more intimate social problems of rehousing the family. Hitherto, the social scientists have been able to do little to influence such plans, but the fruits of their research have had considerable potential value and ought not to be neglected. To the observer of the discussions relating to these papers the day's work was stimulating ; but sometimes there crept in a doubt about whether some of the more basic questions were being missed. There were so many different views on how the needs and aspirations of a planned community could be measured ; it was therefore disturbing to feel that the experts had not reached any solid basis of agreement.

The third section of the conference—on "Needs and Standards in the Social Services"—began by considering social security in the epoch following the Beveridge Report. Recent years have brought about developments which were not foreseen when the scheme was planned. Ever-increasing demands are being made on the central exchequer to supplement the allowances paid under national insurance. These allowances fall substantially below the minimum subsistence requirements as assessed by the scale of need of the National Assistance Board. In 1952, 24 per cent of the households drawing retirement pensions were receiving supplementary assistance compared with 18 per cent four years previously, and the same trend is apparent in the other branches of national insurance. Clearly it would be impossible to raise the level of contributions to make the scheme actuarially sound. Would it therefore be better to drop the figment of a contributory insurance and finance the entire scheme out of general taxation ? Or should one follow some other British Commonwealth countries and raise the money through a progressive social-security tax ? In such a case should there be progressive rates of benefits, thus taking account of the fact that different people have different needs ? Would it be advisable to develop some branches of social security as self-supporting insurance schemes—for example, those providing for short-term crises such as sickness or unemployment —while financing the remainder out of general taxation ? These were some of the questions raised in the discussion. There was a general feeling that the abandonment of the principle of a contributory insurance for the purpose of economy and simplification in administration would, in the popular mind, entail the abandonment of the right to benefit. This right is held dear by working people, particularly in regard to unemployment. The imposition of a test of need would be considered as harking back to the days of the means test and the Poor Law. There is some recent evidence to show that there is still reluctance to claim assistance on the part of unemployed workers. Old people, too, it has been said, like to feel that they have something which they have earned, contributed or 'put by' for themselves and generally deplore the idea of charity.

It seems desirable that the purpose of the various social-security schemes be thought out and defined more clearly with the view of bringing about modifications designed to meet the needs for which they were intended.

The group turned to subsistence standards and to methods of measurement in social science. A method of measuring poverty that takes into account the actual purchasing behaviour of people was discussed and shows promise of an improvement over its precursors. Then followed a discussion on the advantages and limitations of social survey techniques. It was agreed that such investigations could provide accurate factual data on the problem of needs and standards in the field of social insurance, but there was a lively debate on their value to the administrator in policy-making and in assessing priorities in the field of social welfare. Here the question of values which had obtruded itself many times in the conference came to the fore. Social scientists cannot claim the right to pronounce on how value judgments are to be made, but—and perhaps this was a keynote of the meeting—they can provide factual data by which such judgments can be considered and made more rationally.

---

# INSECTICIDES AND COLONIAL AGRICULTURAL DEVELOPMENT

SOME eighty representatives of Colonial agricultural administration, of applied entomology, and of insecticide research and development were invited to Bristol by the Colston Research Society during March 23–27 to take part in a symposium dealing with insecticides in relation to Colonial agricultural development. The conference, which had the support of the Colonial Office and the Agricultural Research Council, was directed by Prof. T. Wallace, head of the Bristol University Agricultural and Horticultural Research Station at Long Ashton.

In the opening session, Dr. W. G. Hall (Commonwealth Institute of Entomology) stated that entomologists have been appointed in only fourteen of the thirty-eight British Colonies. The Colonial Empire, totalling 2½ million square miles, with a population of 70 millions and an annual export of crops valued at £182 million, employs, in all, 29 entomologists. Dr. Hall referred to the coming expiry of the Colonial Welfare and Development Act in 1956 and expressed the hope that ample funds will be made available to continue the pest-control work initiated by that Act.

Mr. C. B. Symes, of the Colonial Office, outlined the insecticide research programmes in the British Colonies, emphasizing the uses of the chlorinated hydrocarbons on pests of food plants. He pressed for an increase in fundamental work on specific Colonial problems.

Mr. S. Callaway, of the Chemical Defence Experimental Establishment, Porton, gave a detailed account of an air-spraying operation against locusts in Tanganyika, in which a spray of 20 per cent dinitrocresol in oil destroyed 4¼ million locusts (96 per cent of the original population).

In the discussion on these papers, several speakers questioned the practicability of introducing insecticide treatments on peasant-grown crops. Sir Harold Tempany pointed out that the yields from peasant holdings are exceptionally low and will have to be increased because population is outpacing food production. Mr. W. T. Cowan noted that co-operative societies of native cotton growers are starting in Uganda.

In the afternoon session of March 24, Mr. E. O. Pearson (Empire Cotton-Growing Corporation) said that the control of jassid on irrigated cotton in the Sudan is the only instance in Africa of large-scale insecticide applications to this crop. He considers that the employment of insecticides on peasant cotton awaits a more orderly system of farming and an increase in basic yields by improved cultivation and manuring.

Mr. R. S. McKinlay (East African Agriculture and Forestry Research Association) described a method of assaying *Lygus* damage to cotton by using weekly spraying of individual rows with DDT and toxaphene to provide pest-free plants for comparison of yields with those of surrounding *Lygus*-infested rows. He suggested that the inevitable delay in extending insecticide treatments to peasant crops might give time for the perfection of effective techniques.

In the discussion, Mr. Pearson recorded that the United States yields, being ten times those of Africa, carry a much higher cost of spraying. Mr. Leyland Cole deprecated the use of over-crude methods for applying the potent modern insecticides. A question on developments in the Congo elicited the reply that a much greater degree of direct control of agriculture is established there than in British colonies. Mr. McKinlay believes that the peasant cultivator can be taught to use insecticides but that it will be a slow process.

On the second day, Mr. G. Swaine (Department of Agriculture, Tanganyika) recorded experiments showing that treatment of cotton with five applications of 10 per cent DDT plus 3 per cent BHC greatly increases yield by controlling American bollworm. On coffee, the Pentatomid bug ***Antestia lineaticollis*** is now widely controlled in East Africa by DDT emulsion. Contact insecticides have given striking results when applied as seed dressings or mixed with soil; for example, BHC against termites or sugar-cane white grubs, aldrin and BHC against the wheat pest, *Heteronychus consimilis*, and toxaphene against cutworms.

Mr. M. J. Way (Rothamsted Experimental Station) described certain ecological balances between pests and predators that might be adversely affected by insecticides. In Zanzibar the *Theraptus* bug attacking coconut palms is often kept in check by a predatory ant. This ant, however, encourages the mealy bug suspected of being the vector of a virus attacking clove trees. A similar relationship between ants and mealy bugs exists on cacao in West Africa.

Mr. J. Bowden (Agricultural Department, Gold Coast) described the damage done by insects to the African's principal food crops—maize, sorghum and millet.

During the discussion it was stated that seed dressing with BHC uses only one-tenth of the quantity of material employed in broadcast applications, but still gives a residual effect. The phytotoxicity of BHC to tobacco seedlings was noted.

In the afternoon, a paper by Mr. R. G. Fennah (Imperial College of Tropical Agriculture) was read by Mr. D. B. Murray. Mr. Fennah considers that, in the West Indies, losses due to the inefficiency of agricultural methods far outweigh those caused by insects. The successes so far gained by insecticides in that area are the suppression of the sugar-cane froghopper in Trinidad and the simplification of parasol ant control.

Prof. J. W. Munro (Imperial College, London) warned the conference that transfers of native labour from subsistence agriculture to industry will bring famine nearer, unless satisfactory storage and transport of foodstuffs can be provided. Much existing knowledge of stored-products pest control is not being used. Prof. Munro emphasized the importance of training selected Africans and West Indians as technicians in the practice of storage pest destruction.

In the discussion, Dr. Jepson said he hopes that the development of agriculture as a subject of study in African universities will be encouraged by the provision of sufficiently attractive posts for Africans trained in agricultural science. He described the methyl bromide fumigation of the groundnut 'pyramids' at Kano as an outstanding example of co-operative effort. Mr. Swaine explained the method of pit storage in Tanganyika, which depends on the production by hermetically sealed grain of sufficient carbon dioxide to act as a fumigant. Dr. R. C. Fisher directed attention to infestations of timber, and outlined the activities of the West African timber-borer research team appointed by the Colonial Office to study infestation in logs before export.

The first paper of the morning session of the last day of the Conference was a general review by Sir Thomas Dalling (Food and Agriculture Organization, Rome) of the insect-transmitted diseases of livestock in Colonial territories. This was followed by a film and paper by Dr. J. Carmichael (formerly of the Uganda Veterinary Department) describing tsetse control in Zululand by application of DDT aerosols from Anson aircraft. Seven such applications in the period September 1950 to January 1951 reduced tsetse populations by 97–99·9 per cent.

Mr. H. E. Harbour (Cooper Technical Bureau) referred first to the earlier treatment of ticks on livestock by sodium arsenite dips, and the development of arsenic-tolerant tick populations. At present, BHC, DDT and toxaphene are making great contributions to tick control. In two areas in Tanganyika tanks have been installed and compulsory dipping instituted. As substitutes for dipping tanks, spray 'tunnels' are proving effective.

The discussion was opened by Dr. J. C. Matthysse (Cornell University), who has been working on ticks in Rhodesia under the auspices of the Mutual Security Agency. He described systems of pen spraying of cattle, using itinerant spray teams. Dr. J. T. Martin suggested that the cost of derris treatment against warble flies might be lowered by the use of synergists. Mr. Symes described the contribution of the workers at Porton in the design of pumps and nozzles for tsetse-eradicating sprays.

In the final session, Dr. H. G. H. Kearns (Long Ashton Research Station) stressed the fact that the successful solution of a spraying problem must take into account the biology of the pest, the spray material, the culture of the crop, the machinery and the user. Present designs, particularly of small manual sprayers, are capable of much improvement, but low-priced standardized designs necessitate large orders. 'Air-flow' mist sprayers can be used for drift spraying only in exceptional cases, as in locust control. Appreciation by the engineer of the biologist's problems is fundamental to the development of satisfactory equipment.

Dr. E. Holmes (Plant Protection, Ltd.) summarized the magnitude and cost of the search for, and development of, new insecticides. He emphasized the necessity for the overseas user to give the manufacturer ample time to ship materials to ensure their delivery at a given date. He referred to the benefits that are accruing from the closer co-operation between official research workers and those from industry.

In the discussion, Mr. Higgins mentioned that the training of entomologists at the Imperial College, London, includes instruction in the use of spray machinery. Mr. Hoare stressed the importance of obtaining exact data on spray deposition and offered the use of an electronic deposit analyser. Mr. Joyce described low-volume spraying in the Sudan, using 25 per cent DDT concentrate at just over ½ gallon per acre. Mr. Symes considers that until formulations of insecticides and designs of machinery are based on much more fundamental research there will be much guesswork in pest-control procedures.

Throughout the conference the outstanding value of co-operation between home and overseas workers was apparent, and it was made clear that one of the immediate problems in Colonial agriculture is the reconciling of peasant cultivation with the need to increase food production by modern methods of pest control. R. W. MARSH

# NATIONAL RESEARCH DEVELOPMENT CORPORATION

## REPORT FOR THE YEAR 1951–52

SIR HENRY TIZARD'S cautious reference to the National Research Development Corporation in his Messel Memorial Lecture last July would of itself induce careful scrutiny of the third report of the Corporation, covering the year ended June 30, 1952, which has now been published*. Although in content and arrangement this report differs somewhat from the two previous reports, which were concerned largely with describing the administrative arrangements, internal and external, and the policy it was proposed to pursue, and describes in more detail the kind of work now being done, it still appears that the Corporation has been in operation for too short a period for a sound judgment as to whether the fear is justified that the existence of such a government body will of itself discourage the spirit of adventure on the part of industry. The brief factual account of its work contained in this report gives no indication of any such trend, if indeed such a trend is likely to be reflected in the work of the Corporation itself.

Some 1,736 patents and patent applications have been vested in the Corporation during its first three years, and, of the 1,027 of which the Corporation was first apprised during 1951–52, 491 were from government departments and research councils, sixteen from British Commonwealth official organizations, one from a nationalized industry, eight from industrial research associations, fifty-three from universities, three from charitable organizations and 455 from private firms and individuals. Many of these last-named, of which 432 were British, were not of public importance. Of patent rights in inventions assigned to the Corporation during the year, 414 were from government departments and research councils, three from industrial research associations and twenty-two from universities, out of a total of 445; and of 401 United Kingdom patent applications and 559 United Kingdom granted patents that were held by the Corporation at June 30, 1952, 235 of which were the subject of 776 overseas patents and patent applications, 844 came from government departments and research councils, seven from industrial research associations and eighty-seven from universities. Most of the 199 licence agreements entered into at June 30, 1952, were not yet revenue-carrying, and net receipts from the various assets were £25,676.

During the year details of 361 inventions were the subject of 8,871 circulations to industrial firms and led to 245 inquiries. Of these, and of a further hundred inquiries brought forward from the previous year, 166 eventually proved abortive and 101 were still under consideration at June 30: the balance resulted in licence negotiations, of which thirty-one had been completed and forty-seven were still proceeding at that date. A second group of inventions includes some two hundred government and research council inventions, represented by patents and patent applications assigned to the Corporation, about eighty from universities, and a few from research associations and private inventors. All these cases are somewhat complex, requiring more-or-less constant individual attention. Sometimes the subject-matter is still too immature or tentative or the field of possible application as yet too remote or obscure to call for any action at this stage, but, from this whole group of inventions, nine licence agreements were concluded and thirty-two were still the subject of licensing and development discussions.

From the third group of inventions, of a long-term character, for which no individual enterprise can be found that is prepared to spend money on development, and in which the Corporation has undertaken the financial responsibility for development, some fifteen development projects have been sponsored during the Corporation's first three years, and further details of some of these are given in the report. Electronic digital computers have been the subject of ninety-nine inventions assigned to the Corporation, fifty-nine being from universities, thirty from government departments and corporations and ten from industrial firms. Patents have been applied for in respect of seventy-four of these inventions in ten foreign countries, and the Corporation has given a contract for the supply of four machines similar to that installed according to the design of Prof. F. C. Williams at the University of Manchester, where grants for development have also been made by the Corporation. The Corporation is, too, entering into a further contract for the supply of a prototype of a machine of much-reduced size based upon the development of special techniques which are expected to decrease cost and increase reliability.

The Corporation is assisting with grants of money for staff and materials experimental work at the Imperial College of Science and Technology, London, on a project for hydrocarbon synthesis; and development work at the National Physical Laboratory, Teddington, arising out of Sir Thomas Merton's work on diffraction gratings, and particularly in relation to spectroscopes, is being assisted by the provision of staff. Two industrial firms in the instrument industry have already taken out licences under the patent rights assigned to the Corporation in respect of these inventions. The Corporation has also agreed to sponsor a project, emanating from Sir Harry Ricardo, for a light steam-engine, which is operated off boiler plant designed to be fired with low-grade fuel and which is based on the application to such engines of the considerable engineering processes made during recent decades in the field of light internal-combustion engines. The project is regarded as likely to contribute materially to Commonwealth interests by meeting the need for small prime movers in under-developed regions of the world. A pilot plant in East Africa, where sisal juice is available in quantity for the production of hecogenin, based on a laboratory unit set up under the joint auspices of the East African Industrial Research Board and the Medical Research Council, is being sponsored by the Corporation to provide a centre for more extended study of the methods of extraction and processing. In the field of scientific instruments, the Corporation has undertaken, jointly with an industrial firm, the development of a British photogrammetric plotting instrument from an invention of Prof. E. H. Thompson, professor of surveying in University College, London; and, in order to accelerate production, it has, with Board of Trade approval, undertaken a share of the financial risk involved in the development of an aural microscope and chick-sexer from the invention of Mr. C. S. Hallpike, of the Otological Research Unit of the Medical Research Council.

# TESTING OF BEARING PROPERTIES OF METALS

ENGINEERS and metallurgists have long been faced with the problem of assessing the bearing properties of any particular bearing alloy. One obvious method (and perhaps the best) has been to test the materials under practical working conditions; but, although this may be effective, it is extremely costly and slow. For these reasons a number of simplified empirical methods have been devised which aim at providing a useful 'figure of merit'. In a paper on "Some Experiments with Sleeve Bearing Metals" (*Trans. Danish Acad. Tech. Sci.*, No. 2; 1952), Dr. Borge Lunn has described another test of this type. As he points out in his introduction, it has generally been recognized as a defect of existing hydrodynamic theory that it does not take into account the nature of the journal or bearing material. In practice, however, the behaviour of a bearing is very markedly dependent on the type of lubricant and bearing material used, and this, in turn, is associated with the frequency and extent to which the hydrodynamic film is penetrated. Dr. Lunn's test has therefore been primarily designed to give a measure of the breakdown and penetration of the lubricant film.

The experimental arrangement is a development of that described by Kauppi and Pedersen[1]. It consists of a hard steel ball which reciprocates over the surface of the bearing alloy at a frequency of about seventy strokes a minute, the load being of the order of several kilograms. The rubbing surfaces are insulated and the electrical resistance between them measured during the reciprocating motion. The method is similar to that described by Courtney-Pratt and Tudor[2] and by Popinga[3] in their investigation of the lubrication between the piston ring and cylinder wall of a running engine, and shows results of the same type. When the surfaces are instantaneously at rest the resistance is low, indicating some metallic contact or, at best, a regime of boundary lubrication. During the central part of the stroke the resistance fluctuates between high and low values as a fluid film is built up and then punctured. Further, as a result of a running-in effect, there is an overall increase in the resistance during the first few minutes of the test, a steady state being reached after several hundred strokes have taken place. Dr. Lunn's procedure is to determine the average resistance during the first 250 sec. of running by a current-potential method using a pen-recording voltmeter of relatively low frequency. The difference (expressed as a percentage) between the full potential drop obtained when the surfaces are completely separated by a fluid film and the average potential drop observed in any particular experiment is then taken as a measure of the breakdown of the lubricant film. The '*L*-values' so obtained are found to vary with the bearing alloy examined and with the lubricant used. Thus a good combination, implying little breakdown of the lubricant film, gives an *L*-value of 10–20 per cent, a poor combination 80 per cent and a bearing using a silicone oil as much as 95 per cent.

Dr. Lunn finds that with tin-base bearing alloys the *L*-values obtained are lower when the alloy is quickly solidified. The *L*-values are decreased when lead is introduced in place of copper and antimony and, to a smaller extent, in place of tin. With bronze alloys the presence of a phosphide eutectic produces a low *L*-value.

Ageing of the lubricant usually produces a reduction in the *L*-value implying improved lubricating properties, while the presence of an antioxidant gives poorer lubricating properties. As a result of these investigations, Dr. Lunn suggests that the effectiveness of a bearing-lubricant combination depends on the formation of a suitable surface film as a result of chemical reaction between the rubbing metals, the lubricant and the surrounding atmosphere. In addition, Dr. Lunn claims that his *L*-value provides a single 'figure of merit' which agrees well with practical performance. It would be interesting to see this extended to other materials and to see if the order of performance is significantly changed by simple alterations in the experimental conditions.

# NOISE FROM AIRCRAFT AT SUPERSONIC SPEED

REFERRING to recent correspondence on this topic in *Nature*, Dr. E. Esclangon has directed attention to two communications by him published in the *Comptes rendus* of the Paris Academy of Sciences. The first, published on November 17, is "Sur les détonations balistiques, engendrées par les projectiles et les avions supersoniques", and the second, published on November 24, 1952, is "Sur les sifflements de projectiles et bruits d'avions en vitesse supersonique". Dr. Esclangon's views on the acoustic effects of supersonic aircraft are based on his extensive work on the shock waves of projectiles during the First World War, published in 1925 in "L'Acoustique des Canons et des Projectiles" (Paris: Gauthier-Villars, 55 Quai des Grands Augustins, Paris 6^e^).

Dr. Esclangon points out that aircraft do not differ essentially from projectiles in the production of shock waves, except that they carry very noisy contrivances which add to the disturbance resulting from their movement alone. The distinction is emphasized between (1) the continuous and uniform disturbance due to the pushing aside of the air, and (2) the periodic disturbances due to the rear turbulence and precessional movements of the projectile and to the roar of the jets of the aircraft.

For the uniformly evolved disturbance, the arrival at a distant observer's position $P$ of disturbances set up over an element of the trajectory will be simultaneous and in correct phase to produce considerable amplification, and the resulting bang will be all the greater as the size of the moving body is increased. The 'ballistic wave' (to use Dr. Esclangon's term) is a closed surface for a body the velocity of which is increasing through the velocity of sound, consisting of two sheets, a forward one of conical form and a rear one more nearly spherical, the two merging tangentially. More than two 'ballistic detonations' may be perceived, depending on the shape of the trajectory.

In his second communication, Dr. Esclangon considers the periodic disturbances. He points out that these are generated in an element of the trajectory in the period of the disturbance which will arrive at $P$ simultaneously; but in all phases corresponding to the period and which, added algebraically, will destroy the periodicity. If the mean pressure is not zero, it will add to the ballistic wave. Dr. Esclangon gives details of a critical experiment. An observer was placed near the point of impact of a large inert projectile fired from a gun at a distance of 54 sound-seconds. The speed of the projectile was, at all points of the trajectory, greater than that of sound, and the duration of its flight was 37 sec. It was expected that after the ballistic wave had arrived the whistling of the projectile would be heard in reverse for 17 sec.; but in fact nothing at all was heard. Dr. Esclangon finds difficulty in explaining this, although the experiment would appear to emphasize the fact that the bang is predominantly due to the ballistic wave and that the whistling from the remote beginning of the trajectory is too feeble to be heard.

After pointing out the possibility of further study through the medium of supersonic aircraft, Dr. Esclangon concludes with a forecast that, as the ballistic wave appears when the speed of the aircraft resolved in the direction of the observer equals the speed of sound, a flight path in the form of an equi-angular spiral, centre $P$, would make $P$ a sort of focus for a particularly powerful 'acoustic detonation'.

# MARINE BIOLOGY RESEARCH IN GREAT BRITAIN

FIFTEEN papers on the species and habits of marine animals, the chemical constituents of sea water and the utilization of these substances by living animals and plants, etc., make up the contents of the last (No. 3) number of Vol. 31 of the *Journal* issued by the Marine Biological Association of the United Kingdom.

Dr. D. P. Wilson has continued his experiments on the settlement of *Ophelia bicornis*. Earlier work had shown that there is a range in the size of particles suitable to larval metamorphosis; but Dr. Wilson has now discovered that an organic film on the sand particles of suitable size renders them attractive to the larvæ, whereas sterilized sand of similar particle-size is repellent, with a neutral category between these two extremes. D. B. Carlisle records three species of *Trididemnum*. J. A. Allen has made an exhaustive study of more than two thousand five hundred specimens of *Nucula turgida* and *N. moorei*, and shows that they grade into one another, representing, in fact, a single species, *N. turgida*. Prof. N. Millott, while on a visit to Plymouth from Jamaica, investigated the skin pigment of *Holothuria forskali* and found that the cœlomic amœbocytes produce melanin for the skin pigment and that this production is coupled with the presence of an active phenolase system. G. Hoyle has studied spontaneous squirting in the ascidian *Phallusia mammillata*. Rhythmical patterns of activity in sedentary animals occur also in *Metridium* (Batham and Pantin, 1950) and *Arenicola* (Wells, 1949). This activity, which is inherent, is modified by external stimulation, but is not initiated from without. The inherent activity may be myogenic, "with considerable neurogenic control". Spontaneous squirting of certain ascidians is an integral part of their feeding mechanism, and clears out waste from both the pharyngeal and atrial cavities. Dr. D. T. Gauld and Prof. J. Raymont contribute a paper on respiration in the copepods *Temora*, *Acartia* and *Centropages*, in which they point out that estimation of the food requirements of copepod populations based on the respiratory-rate, as used by other workers, is unreliable unless the size distribution of the copepods making up the population is known. Moreover, at least in *Centropages*, different generations of the same species may, for unknown reasons, have different respiratory-rates, and temperature is therefore not the sole cause of variation. Dr. Gauld has also studied the grazing of copepods, chiefly *Calanus finmarchicus*, and has found that some fed continuously during a twenty-four hour period near the surface, not migrating downwards, while others underwent vertical migration and fed only at night near the surface. There is thus no general feeding rhythm, as postulated by certain workers.

Dr. W. R. G. Atkins and Miss P. G. Jenkins have examined monthly for a year the phytoplankton from a station ten miles south-west of the Eddystone Rock, between the surface and fifty metres depth. For the surface the maximum was in March, the minimum in June, with a moderate rise in September and a winter minimum in November. The botanical composition of the water was studied after culture in diffuse light in the laboratory, twenty species of diatoms, eight members of the Chlorophyceæ, and one each of the Chrysophyceæ, Dinophyceæ and Cryptophyceæ being recorded. Mr. R. F. Hutton describes a new furcocercous *Cercaria*, *C. reesi*, from the digestive gland of *Hiatella arctica* and *H. striata*. Dr. J. S. Alexandrowicz has continued his investigations on the nervous system of marine arthropods by observations on the nerves of the pericardial organs of the decapod Crustacea. He finds evidence that these organs, bathed directly by blood from the gills, produce substances influencing the heart rhythm.

Dr. H. W. Harvey has two papers on the utilization of chemical substances in sea water by *Nitzschia closterium*. This diatom can absorb organic phosphorus when inorganic phosphorus in solution has been exhausted, both in light and in darkness. Nitrogen-deficient cells can also synthesize organic nitrogen in darkness from ammonium, nitrate and nitrite, with intensity decreasing in that order, and also chlorophyll and yellow pigments. Dr. W. R. G. Atkins has resumed his work on the phosphate and silicate content of sea water, and compares the data with those for the 1923–25 period. He also reports on the seasonal variation in the copper content of sea water; this builds up in the winter and drops from May onwards, with a minimum in October.

Tests with materials for the preservation of fishing nets, by Dr. Atkins and Mr. F. J. Warren, showed that on cotton netting 'Cuprinol', or Dr. Olie's method with cutch and ammoniacal copper sulphate, worked well, the latter being the cheaper of the two, while on trawl twines 'Cuprinol' (British Columbia grade) was best. Work on the preservation of ropes is proceeding. This number of the *Journal* concludes with abstracts of memoirs recording work done at the Plymouth Laboratory and published elsewhere.

# ARTIFICIAL STIMULATION OF RAIN AT KONGWA

DURING January–April 1952, cloud-seeding experiments for the artificial stimulation of rain were carried out at Kongwa, Tanganyika, in connexion with the growing of groundnuts and other crops there by the Overseas Food Corporation. The director of the East African Meteorological Department, Mr. D. A. Davies, has already described the methods used (see *Nature*, 169, 1001; 1952), and now the results of the experiments have been published in the Department's "Memoirs"* and they prove to be very surprising.

The full details of the methods need not be given in this article, but, briefly, the seeding agents were released in a three-day cycle: silver iodide was released on the first day at a height of 14,000–15,000 ft., and hygroscopic particles (sea salt) at about 5,000 ft. on the second day. On the third day there was no seeding. Balloons carried canisters containing the seeding agent, which was released by exploding a small gunpowder charge by a time-fuse after a time of flight to bring the balloons to the desired height. The balloons were released downwind at a distance measured each day to ensure scattering of the particles over the same point at the centre of the farm area. Silver iodide is effective only at temperatures below − 5° C. and so had to be released at a much greater height than the hygroscopic particles which were released in the lower part of the cumulus clouds. Rainfall was measured by a network of gauges distributed over the roughly rectangular area, 22 miles by 7 miles in size, occupied by the farm area. The long side of the rectangle lay from east to west. The wind was easterly for nearly all the 114 days of the experiments. There is a ridge of high land running from north to south in the centre, and rainfall is normally appreciably greater there than in the eastern and western ends of the area.

The results are presented in isohyetal maps showing rainfall on all the days of each type of seeding and no seeding, with comparison with normal. There is no description of the rainfall of any individual day. The overall results are briefly as follows. (*a*) On days of seeding in both ways, the rainfall in the central area over which the particles were released was reduced from a total of 9 in. on days of no seeding to one of 3–4 in. for the days of each type of seeding; seeding thus appears to have produced a great decrease of rainfall over the central area. (*b*) On days of releasing hygroscopic particles, the rainfall in an area 6–12 miles downwind was above that on days of no seeding by up to 6 in.; rainfall over an area 5 miles upwind was also increased by 2–3 in. (*c*) On days of releasing silver iodide particles, rainfall upwind from the point of release was increased by at some places more than 6 in.; downwind there was a small decrease. (*d*) On some occasions, clouds in which hygroscopic particles had been released were seen to disperse rapidly.

The memoir explains the increase of rainfall 6–12 miles downwind on days of seeding with hygroscopic particles by the delay in formation of large drops. No reason for result (*c*) is suggested in the memoir, and there is no mention of a reversal of wind with height to carry the silver iodide particles to the east and so stimulate precipitation there.

On thirteen days when particles should have been released, it was already raining and balloons were not released because the fuses would have been extinguished. These days have been counted in the statistics as though seeding actually took place. As the memoir says, this makes the rainfall deficit in the central area even more surprising.

# FORMATION OF GALL STONES: PHYSICAL PROPERTIES OF BILE SALTS

By A. J. H. RAINS and N. CRAWFORD
Surgical Professorial Unit, Queen Elizabeth Hospital,
Birmingham

STONE formation in the various secretory or excretory ducts of the human body is one of the problems being studied in this Surgical Unit. The gall stone is the particular type of stone selected for study, especially that which, as a rule, primarily arises in the gall bladder—the pure cholesterol and the mixed gall stone, as opposed to the pigment or metabolic stone which arises in the hepatic ducts.

Pure cholesterol stones, single or multiple, are uncommon, for usually bile pigments, among other compounds, are included in varying amounts, either diffusely or by way of lamination, so that mixed stones are the rule. Because pure cholesterol stones exist with varying amounts of pigment, it is likely that the latter is an inclusion and that the prime disturbance involves the cholesterol. This is the 'crystallization out' of cholesterol; but the chemical reaction which starts this off, or the character of the nucleus around which the cholesterol stone forms, is unknown, even though Wilkie[1] noted that granular calculi of calcium and cholesterin were formed in the infected bile of an experimental animal. Gall stones have not been produced, at least convincingly, by any other means.

Two important contributory factors (or pieces of circumstantial evidence) in the formation of these gall stones are hypercholesterolæmia and infection; but to these a third factor should be added, namely, the power of the gall bladder to concentrate bile.

Associated with cholesterol are the salts of the bile acids, in the solutions of which the sterol is dissolved, and it was therefore considered that any chemical study of the factors responsible for the formation of gall stone must commence with the exploration of the cholesterol – bile acid relationship, first with the physico-chemical properties of the salts of the bile acids.

The inference that the molecules of bile salts should exhibit physico-chemical characteristics similar to those of the paraffin-chain salts may be drawn from the fact that in structure they contain water-attracting and water-indifferent parts—they are 'amphipathic'. Like the paraffin-chain salts, they have foaming, detergent and emulsifying properties, consequent upon their power to reduce surface tension.

McBain[2] put forward the micelle theory in order to explain the abnormal curves produced by plotting equivalent conductivity or the depression of freezing point against varying concentration of certain colloids (paraffin-chain salts) in solution. With the increase in concentration, a critical point is reached when an abrupt change in the slope of the curve or a discontinuity may be considered to be due to a change of phase ; in fact, ionic aggregation or micelle formation, as McBain called it, begins and extends over a certain range.

In Hartley's[3] contribution to the fuller understanding of the phenomenon, attention was directed to the fact that the salts of nucleic acid and possibly bile acids might undergo micelle formation at appropriate concentrations, though no experimental work on the latter had been done at that time.

Some particular observations of bile acid salts have been made since Hartley's paper ; Bashour and Baumann[4], Roepke and Mason[5], and Johnston and McBain[6] conducted experiments in order to study the equivalent conductivity and depression of the freezing point at varying concentrations of different salts. The results showed that although there was no sharp change in the slope of the equivalent conductivity – concentration curves, the osmotic coefficient – concentration curves, as measured by the depression of freezing point or the vapour pressure, did in fact indicate ionic aggregation. McBain considers that the measurement of equivalent conductivity alone may not give direct evidence of the formation of ionic micelles. The bile salts studied were sodium cholate, deoxycholate, glycocholate and glycodeoxycholate at temperatures of 20° C.[4], 25° C.[5] and 0° C.[6]. The temperature of a solution known to show evidence of ionic aggregation is important, for it will affect the critical concentration at which the micelles begin to form and the range over which they continue to do so. As the bile salts occur naturally in the animal world, their propensity for micellar forms were studied by us at 37–38° C., that is, at the normal environmental temperature of man.

The bile salts examined are among those commonly present in human bile : sodium cholate, deoxycholate, glycocholate and taurocholate, and the properties studied were equivalent conductivity, osmotic pressure, surface tension, turbidity and viscosity in order to detect any evidence of change of phase.

*Methods*. The bile salts were obtained from Ward, Blenkinsop and Co., Ltd., together with a statement of their purity. All the determinations with the exception of freezing point were performed without removal from the water-bath, which was thermostatically controlled at 37° ± 0·5° C. by a Kodak 250-W. heater and a Sunvic *T.S.I.* bimetal thermostat with relay.

Conductivity measurements were made with a Mullard conductivity bridge, Type *E*7566 (range 0·1–100,000 micro-mhos). The conductivity cell was the dip-cell Type *E*7591 supplied with the instrument and had a cell constant of 0·79. The water used for making up the solutions had a conductivity of $3 \times 10^{-6}$ mhos, thus limiting reliable measurements to concentrations greater than $M/320$.

The osmotic coefficient $g$ was calculated from the relation

$$g = \frac{\Delta t}{(2 \times 1{\cdot}858 \times m)},$$

where $\Delta t$ is the depression of freezing point in degrees and $m$ is the molarity, $g$ thus being the ratio of the value of the observed lowering of freezing point to that which would be expected for an 'ideal' fully dissociated electrolyte. $\Delta t$ was measured with the conventional type of Beckmann freezing apparatus.

Relative surface tension values were determined by a stalagmometric method employing a Steiner pattern stalagmometer. In spite of ensuring that a drop number of 15 per min. was not exceeded, it was realized that this method could not give reliable values of relative surface tension, though interesting and significant results were obtained by a simple comparison of drop numbers. For maintenance of temperature during surface tension experiments, the stalagmometer was fitted into an air jacket and the whole unit submerged in the water-bath to below the level of the top graduation of the stalagmometer.

Relative viscosity readings were made with a Steiner pattern No. 1 viscometer inserted into a water-bath well above the highest graduation.

Photographs were taken of the bile salt solutions at times when changes in turbidity became apparent. In most cases this occurred within a day or two of making up the solutions, and microscopic examinations were carried out to eliminate the possibility of interfering fungoid contamination.

*Results*. Graphs of conductivity and the effect on surface tension were constructed for each particular bile salt. For the sake of brevity, a composite graph of a simple and a conjugated salt is shown (Fig. 1). The curves for the other bile salts studied showed similar characteristics. The range of concentration commences at $M/5$ and decreases to $M/1,280$. Sufficient quantities of the bile salts were not obtained to enable concentrations higher than $M/5$ to be studied and, due to possible limitations in sensitivity of the apparatus and the methods employed, figures for concentration less than $M/320$ were not plotted, although results were obtained. The surface tension values are expressed simply as drop numbers and are plotted as such.

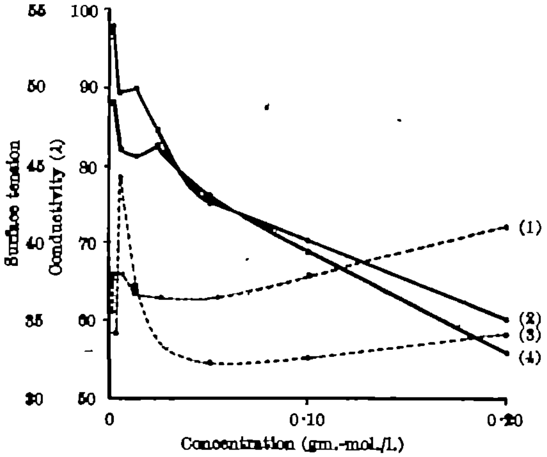

Fig. 1. Conductivity (full line) and surface tension (broken line) at 37° C. of: (1) and (4) sodium deoxycholate ; and (2) and (3) sodium glycocholate

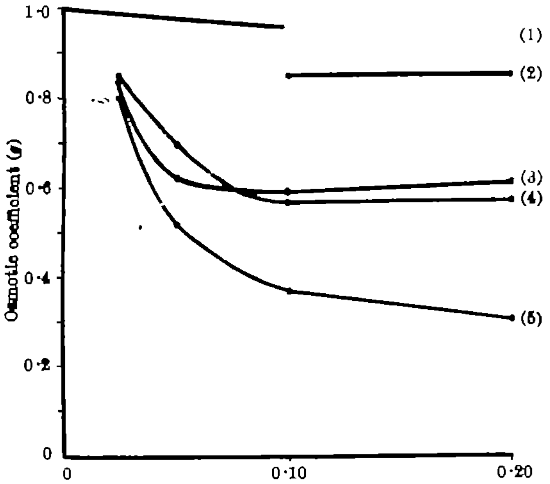

Fig. 2. Osmotic coefficients of: (1) potassium chloride; (2) sodium taurocholate; (3) sodium glycocholate; (4) sodium cholate; (5) sodium deoxycholate

It was not found possible to determine freezing point depressions at a concentration lower than *M*/40; in particular this was the case with sodium taurocholate—even at *M*/20. These curves are shown together (Fig. 2). In addition, the conductivity and osmotic coefficient values were compared as percentage decreases over the range *M*/40–*M*/10. It was found that although the osmotic coefficient for deoxycholate and glycocholate decreased by 54 and 30 per cent, the conductivity decreased by only 17 and 4 per cent, respectively. This may be of importance in assessing relative tendency to micelle formation by the bile salts, for Hartley, with paraffin-chain salts, and Roepke and Mason, with sodium cholate and glycodeoxycholate, believed such large differences of these properties to indicate appreciable association of bile acid ions.

Observations were made on the turbidity of the solutions 48 hr. after making them up, and photographs were taken under normal studio lighting conditions. Sodium deoxycholate and glycocholate produced markedly turbid solutions between concentrations of *M*/1,280 and *M*/160; from *M*/80 to *M*/5 they were crystal clear. Taurocholate showed the change at *M*/40, though not so abruptly. Sodium cholate solution showed no turbidity at any concentration.

Values for viscosity were obtained, but the limitations of a simple viscometer in such a study, with the difficulty of resolving the values into absolute viscosity, showed that the results could be of no assistance, and they are therefore omitted.

*Discussion.* The equivalent conductivity curves show a change of phase at about *M*/160; at about this point a 'kick' is shown on the graph; this may be due to the commencement of aggregation[3]. The curves are more convincing than those obtained by Roepke and Mason, or Johnston and McBain. The point of change of phase fits in with the point of maximal effect on surface tension, the point at which the abnormal depression of freezing point occurs, and also with the change-over from the turbid to clear state in three of the solutions.

In salts where visual changes were most apparent, namely, sodium deoxycholate and sodium glycocholate, greater differences in the percentage decrease of equivalent conductivity and osmotic coefficient over the range *M*/40–*M*/10 are shown than with sodium cholate, a salt in which no significant visual change occurred, and therefore these two salts perhaps have a greater tendency to micelle formation.

*Conclusion.* The bile salts, sodium cholate, deoxycholate, glycocholate and taurocholate, in solutions of increasing concentration undergo a change of phase which is demonstrated most readily by the equivalent conductivity, osmotic coefficient and surface tension curves, and which is taken to indicate ionic aggregation or micelle formation. Our turbidity findings may well be confirmatory evidence of this. The phenomenon is shown to advantage at 37° C. The range of the concentration of solutions in which these experiments were carried out is likely to occur in the human bile. Further work on the affinity of the bile salt micelle for cholesterol is to be published.

Grateful acknowledgment is made to the Medical Research Endowment Fund of the Birmingham United Hospitals, from which a grant in aid of this work was given. Thanks are also due to Profs. H. J. Melville, F. A. R. Stammers and Melville Arnott for their advice and assistance.

# A HIGH-RESOLUTION AERIAL FOR RADIO ASTRONOMY

By W. N. CHRISTIANSEN

Division of Radiophysics, Commonwealth Scientific and Industrial Research Organization, Australia

IN observations at radio wave-lengths, it is impossible to obtain an angular resolution which is comparable with that of even a small telescope. Even a relatively large object like the sun, which has been studied intensively by radio astronomers, is difficult to resolve at radio wave-lengths. It is known that solar radiation, at radio-frequencies, consists of several components, one steady over a period of months or years, and the others variable. The steady component has been identified[1] with thermal radiation from the 'quiet' or undisturbed sun. A determination of the distribution of brightness over the solar disk of this component would provide information about densities and temperatures in the atmosphere of the sun.

A 'slowly-varying component'[2] of the solar radiation which is prominent at decimetre wave-lengths can be correlated with the area of visible sunspots on the solar disk. Although it is known that this radiation originates in small 'bright' regions near sunspots[3], the shape and position in the solar atmosphere of these regions and their rates of growth and decay are not known.

Until now, most information about the distribution of radio brightness over the solar disk has come from eclipse observations. Such observations, however, have the serious drawback that they can be made only infrequently, and it is not possible to separate with certainty the various components of the solar radiation. The problem requires frequent observations with very highly directional radio equipment.

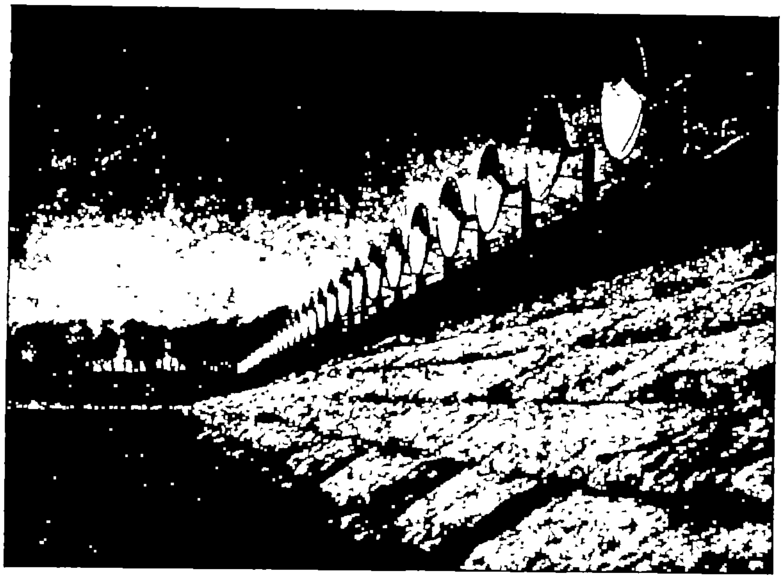

Fig. 1. 32-aerial interferometer at Potts Hill, Sydney

The size of an aerial required to achieve an angular resolution which is small with respect to the sun, say one-tenth of the visual diameter of the disk, is about 1,000 wave-lengths. At a wave-length of 2 decimetres, this corresponds to a diameter of about 700 ft. A rotatable antenna of such dimensions, and with the required constancy of shape, is not practicable.

If the resolution is to be provided in only one angular co-ordinate, the problem is greatly simplified, as the aerial has to be large in only one dimension. The aerial need not then be steered, because the beam is fan-shaped and the system may be arranged so that the rotation of the earth sweeps the beam across the sun. A two-aerial interferometer is a system of this type, but in its normal form is not useful for scanning a complex source like the sun.

A spaced-aerial interferometer with variable spacing between the aerials was used by Stanier[4] in an attempt to measure the distribution of the background component of the radiation at a wave-length of 60 cm. His method requires the solar disk to be free from any localized areas of enhanced brightness, and the background component to be symmetrical with respect to the centre of the disk. It is not clear from the published description how well the first of these conditions was fulfilled during the course of the work.

An aerial system which provides the required angular resolution in one dimension for scanning the sun has been constructed near Sydney. It produces multiple beams, but, unlike the case of a spaced-aerial interferometer with two elements, these beams have an angular spacing large enough to ensure that only one beam can scan the sun at one time. The system consists of thirty-two paraboloidal aerials, each 6 ft. in diameter, mounted individually on polar axes and arranged at equal intervals in a straight line of length about 700 ft. lying in an approximately east–west direction; it operates at a wave-length of 21 cm. (Fig. 1). The individual aerials are connected to a radio receiver by a branching system of open, two-wire transmission lines, arranged as shown in Fig. 2, so that the length of line between each aerial and the receiver is the same.

The system operates in a manner analogous to that of a diffraction grating. A family of knife-edge beams is produced, each beam being 3′ in width and separated from adjacent beams by 1·7°, or about three times the angle subtended by the diameter (visual) of the sun. The rotation of the earth causes each aerial beam in succession to sweep across the disk of the sun. A recording milliammeter at the output of the receiver indicates continuously the magnitude of the radiation being received from the strip of the solar disk to which the aerial beam is directed. The resultant trace is of the type shown in Fig. 3, in which the effect of several successive scans of the sun are seen. The records for each day's observations are averaged to reduce errors produced by random fluctuations in the receiver output.

A feature of the records is the appearance of peaks on the curves, indicating the presence of localized areas of enhanced brightness on the solar disk. As shown in Fig. 4, the positions of these bright areas change from day to day, which suggests that they rotate with the sun. The position of an aerial beam with respect to the solar disk at any time may be calculated from astronomical data and the geometry of the aerial system. From the time at which a peak appears in the output record of the receiver, one can deduce that the corresponding bright area on the sun is located along a certain line on the solar disk. The position of this line can then be compared with the positions of any optical features on the disk. Such a comparison is shown in Fig. 5, where lines indicating the positions of five distinct bright areas

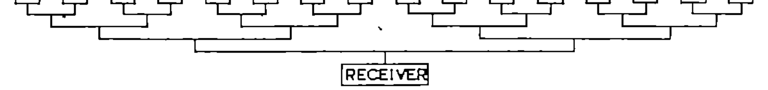

Fig. 2. Arrangement of aerials and feeder lines. The aerial response shows a maximum when the optical path difference for adjacent aerials is an integral number of wave-lengths

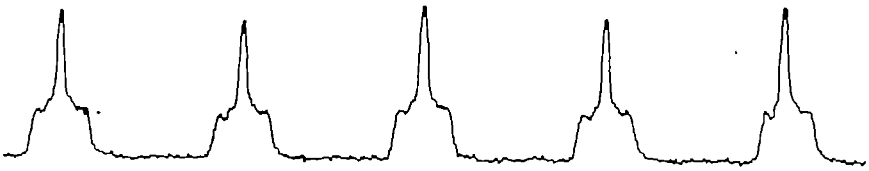

Fig. 3. Record of the sun passing in succession through several beams of the aerial

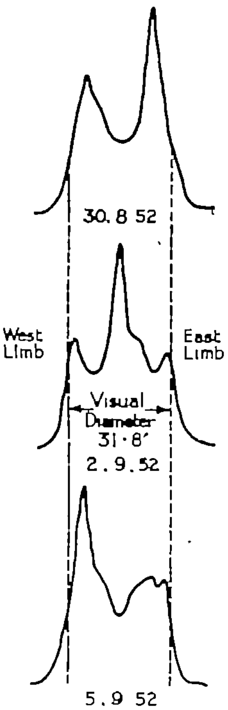

Fig. 4. Records obtained at intervals of several days. The change in position of bright areas is seen

are shown to fall close to sunspot groups.

If it is assumed that the bright areas have no independent movement with respect to the solar photosphere, then a series of daily records of position of any such area can be used for a determination of the heliographic latitude and longitude of the region and also the height of the region above the photosphere. Results to date indicate that the bright regions lie above sunspot groups or close to places previously occupied by sunspots.

The day-to-day variations in the brightness of such a region may be expected to show the combined effects of non-uniformity in angular distribution of emission from the region and of changes in actual emission with time. A statistical study of this should allow the two factors to be separated.

The one-dimensional brightness distribution of the background radiation, or radiation from the undisturbed sun, may be found directly if a record can be obtained during a period when the solar disk is free from areas of enhanced brightness. Alternatively, the distribution may be derived from a succession of daily records if a lower boundary curve is found below which the level never falls. In practice, it has been found that either method involves recording over a long period, even during the present period of low sunspot activity. A series of daily observations has been plotted in Fig. 6. The appearance of a relatively sharp lower boundary to the curves confirms the presence of a background radiation which is constant over a period of at least weeks. The shape of this boundary agrees with records obtained on two occasions when one half the solar disk was apparently free from areas of enhanced brightness. Preliminary results suggest that marked limb-brightening is present.

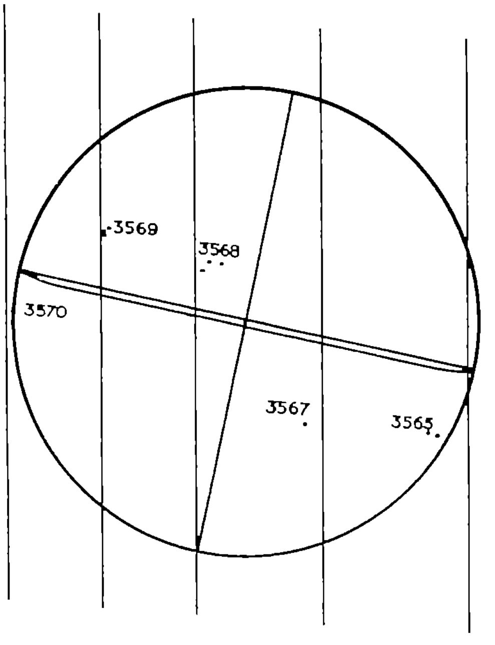

Fig. 5. The position on June 23, 1952, of five areas of enhanced brightness, indicated by lines on a sketch of the solar disk. The positions of sunspots are also shown

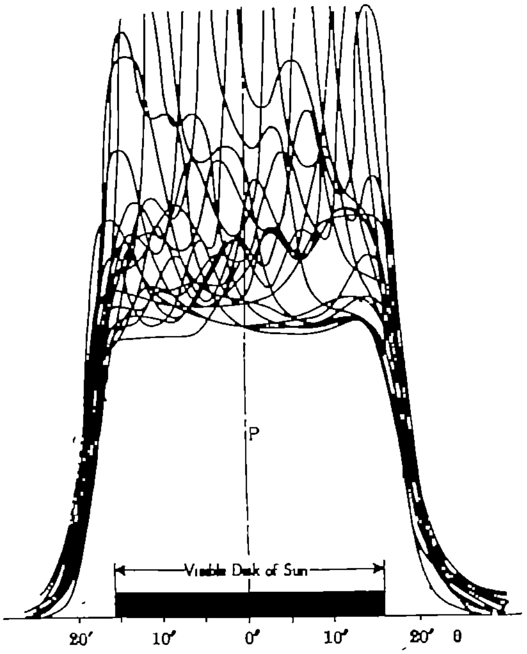

Fig. 6. Combined plot of a series of daily observations showing distinct lower boundary. *P* is the power received, in arbitrary units; θ is the angular separation between the centre of the aerial beam and the centre of the optical disk of the sun

Two series of observations, one made during March and April and one during June and July 1952, have shown a small change in the brightness distribution near the limb. Non-circular symmetry of the source would be a possible cause of this, since in the interval the direction, relative to the sun's axis, in which the sun was scanned had changed considerably. This possibility is supported by eclipse observations[5] at a wave-length of 1·78 metres, which gave a brightness distribution that is not circularly symmetrical. A second aerial system arranged at right-angles to the existing system is being constructed to investigate this.

The observations are continuing and will be further reported in the *Australian Journal of Physics*. I wish to acknowledge the assistance of Mr. J. A. Warburton and Mr. A. J. Harragon in the work, and helpful discussion with Dr. J. L. Pawsey. [Nov. 28.

### Measurements on Superconductivity in Thin Tin Films

Continuing our previous measurements[1] on superconductivity of thin tin films, we have now measured the change in superconductivity, under the influence of a magnetic field and also under the combined action of the current and a magnetic field.

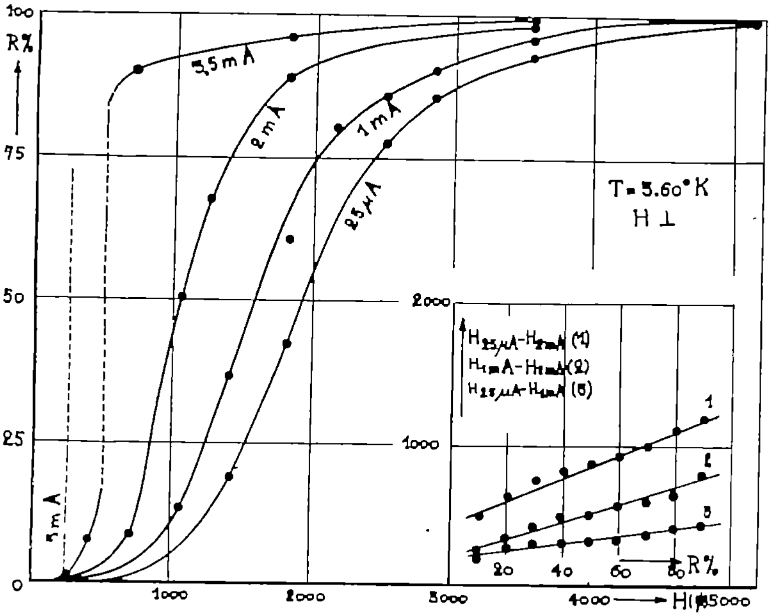

Fig 1

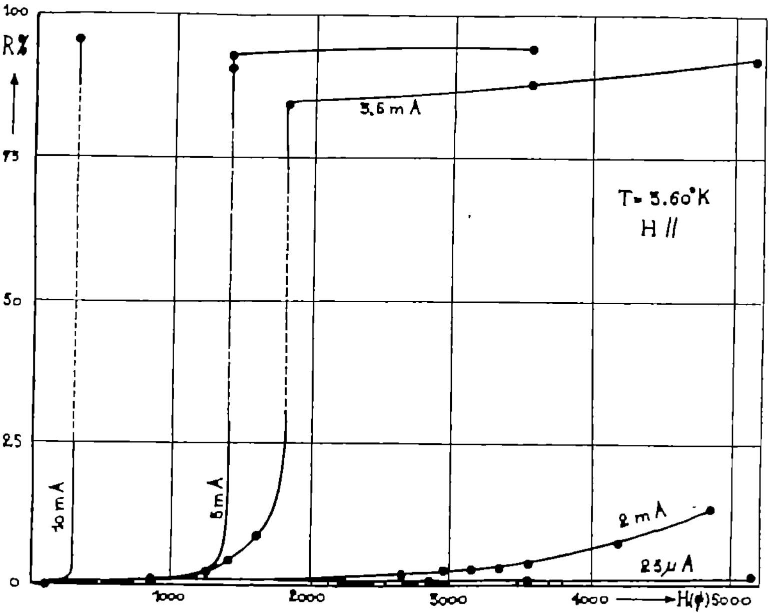

Fig. 2

Our deposits are obtained on small glass strips (length of the film, 5 mm.; width, 3 mm.) by sputtering in argon at room temperature using a cathode of spectrographically pure tin prepared by Johnson Matthey and Co., Ltd. In order to eliminate oxidation, the films are transported to the cryostat in an evacuated tube belonging to our special transport system. In the cryostat the film is dipped into the liquid helium. Hence it is possible to study the change in superconductivity even when using large current densities without the film being warm.

Just as in our previous measurements, we found that, for our films, the transition temperature is a few tenths of a degree higher than for normal tin. The behaviour of one of our films is described in this communication. The resistance of this film at room temperature is 116 ohms, at the boiling point of liquid oxygen it is 104 ohms, and at the boiling point of liquid helium 87·8 ohms. The transition temperature is 3·82° K., and after the transition there remains no residual resistance. This film, and also the others, showed a peculiar effect when we measured the disturbance under the influence of the combined action of an external magnetic field and the current. Figs. 1 and 2 illustrate the influence of a field, normal to the surface of the film and parallel to the film (in both cases perpendicular to the current) respectively, for different currents. The following points may be noted:

(1) By increasing the current, the transition curves become more and more sharp. Experiments of the same kind have been carried out by de Haas, Voogd and Jonker[2] on a monocrystalline tin wire, but they obtained flatter curves when the current was increased.

(2) The critical field for the direction parallel to the film is much larger than for the perpendicular direction. This fact has also been observed recently by Zavaritskii[3]. Moreover, we observed that even for large values of the current, the magnetic threshold value for the film is considerably greater than for the bulk metal.

(3) In Fig. 1 (inset) *R* per cent is plotted as a function of $H_{i_1}-H_{i_2}$, which is the compensating field for the current difference. It is noteworthy that straight lines are obtained.

The same general behaviour was found for this film at other temperatures below the transition temperature, and also for our other films.

We wish to thank the Belgian Department of Education for financial aid for these experiments.

## Temperature of the Interior of the Earth

In a previous communication[1], I gave an outline of a new method for estimating temperatures in the earth's interior. The method was based on what I have called the temperature–pressure hypothesis, namely, that the reciprocal of the volume coefficient of thermal expansion $\alpha$ is a linear function of the pressure $p$ :

$$\frac{1}{\alpha} = \frac{1}{\alpha_0} + bp. \qquad (1)$$

This relation was suggested by the analogous compressibility–pressure hypothesis of Bullen[2] and Ramsey[3], namely, that the reciprocal of the adiabatic compressibility is a linear function of the pressure.

Support for the temperature–pressure hypothesis was obtained using Uffen's[4] values of $\alpha$, which were based on the theory of solids. An independent investigation based on Murnaghan's theory of finite strain has now been carried out, the results of which add further support to the temperature–pressure hypothesis. More important is the fact that the values of the coefficients $1/\alpha_0$ and $b$ in equation (1), as obtained by these two methods, agree to within 10 per cent. Thus two independent lines of attack not only support the general hypothesis, but also agree among themselves as to the numerical value of the coefficients.

Birch[5], however, in his most recent paper on the constitution of the earth, disagrees with the compressibility–pressure hypothesis of Bullen and Ramsey, and regards the linear relationship between the reciprocal of the compressibility and the pressure as at best approximately valid over limited ranges of pressure for the particular materials of the earth's interior. It is not claimed that the temperature–pressure hypothesis is necessarily a fundamental physical relationship ; but it is suggested that, in view of the agreement between two independent investigations, it should give a very fair approximation to the truth. Because of the lack of experimental data, which are both scanty and subject to relatively large uncertainties, the empirical relation (1) should be of considerable help in estimating temperatures within the earth.

The full implications of the temperature–pressure hypothesis are being investigated—in particular, the problem of the transfer of heat from the core. Assuming that the core has the composition of an iron meteorite, an estimate can be made of the conductive flow of heat in the core near the boundary of the core and mantle. Using the adiabatic temperature gradient based on the temperature–pressure hypothesis, a value of $5 \times 10^{-7}$ cal./cm.$^2$sec. is obtained. On the other hand, using the melting point gradient and conductivity of olivine as obtained by Uffen[4], a value of $5 \cdot 5 \times 10^{-7}$ cal./cm.$^2$ sec. is obtained for the conductive heat flow in the mantle near the boundary of the core and mantle. The difference between these two figures is not significant, being within the limit of their probable accuracy. It thus appears that sufficient heat can be removed from the core by conduction alone—a result hitherto not thought possible. This has far-reaching effects on Bullard's[6] dynamo theory of the origin of the earth's magnetic field, which requires a motion of the material of the core. It has been shown that thermal convection provides the only satisfactory mechanism for the generation of such motions. The results of the present investigation show that, in order to have convection in the core, it is not necessary to have convection in the mantle as well. This lends considerable weight to the contraction theory of orogenesis put forward by Wilson and Scheidegger[7] as against the convection current theory.

Finally, Bullard[8] found that the heat flow required to maintain convection currents in the core was about four times greater than that available from a core with a radioactive content comparable to that of iron meteorites. This discrepancy is almost entirely removed if figures based on the temperature-pressure hypothesis are used.

## Tensile Strength of Liquid Nitrogen

Several authors[1] have suggested that included gases have an appreciable effect in lowering the observed tensile strength of a liquid. For this reason it was decided to attempt to measure the tensile strength of a low-temperature liquid which, when cooled below its normal boiling point, would contain none of the normally included gases found in most liquids.

A review of the available experimental methods[2] of measuring the tensile strength of a liquid suggests that the static and dynamic tensile strengths of liquids are different. Since the tensile strength of a solid is a static concept, it seems reasonable to consider the static tensile strength of a liquid as a true measure of its tensile strength. For this reason an adaptation of Vincent's bellows method[3] was used. The apparatus was designed with a spring-loaded bellows, and the whole assembly was immersed in the liquid under test. The tension on the liquid-filled bellows could be varied by adjusting the extension of the spring until the tensile strength of the liquid was reached and the rupture of the liquid column ensued. The maximum observed tensile strength of liquid nitrogen was found to be 3·5 atmospheres at 71·0° K., while the maximum theoretical tensile strength based on the theory of Volmer[4] was calculated to be 60 atmospheres at the same temperature.

An attempt was made to study the tensile strength of liquid nitrogen as a function of temperature. It appears that no apparent relation exists between temperature and observed tensile strength, although one would be expected from previous theoretical work[4,5]. It is possible to explain this fact and the discrepancy in observed and predicted values of tensile strength by assuming a bubble-trapping process in the small surface cavities of the bellows. This suggestion has been made previously[1] to explain the lowering of tensile strength of a liquid by the trapping of bubbles of included gases in the Griffith's cracks in the wall of the container. In our case however, the process will not depend on the trapping of bubbles of normally included gases, but on the trapping of bubbles of nitrogen gas in the walls of the container, the size of the nitrogen gas bubble in the liquid being defined by the existing temperature and pressure of the system.

It is hoped to continue the experiments with liquid helium both above and below the λ-point.

## Paramagnetic Resonance and Covalent Bonding

IN the course of a programme of investigating paramagnetic resonance in compounds containing 4*d* and 5*d* transition elements, we have recently found an unusual hyperfine structure in ammonium chloroiridate, which gives information about the bonding in this compound. The essential experimental result is that in a crystal of $(NH_4)_2[IrCl_6]$, diluted with the isomorphous diamagnetic platinum salt, the resonance spectrum at a temperature of 20° K. and wave-length of 1 cm. shows a complex hyperfine structure consisting of many lines, of which sixteen equally spaced lines can be resolved in the most favourable directions, with overall separation of about 150 gauss. At first sight one would expect only four lines corresponding to the known nuclear spins ($I = 3/2$) of iridium-191 and 193. (The nuclear magnetic moments are approximately equal.) It is possible to explain the presence of the additional lines as arising from the chlorine-35, 37 ($I = 3/2$) nuclei, and the detail of the spectrum by assuming that the hyperfine structure of chlorine is one-third of that of the iridium.

Each iridium ion lies at the centre of a regular octahedron of chlorine ions, and on a purely ionic model these ions would be $Ir^{4+}$ ($5d^5$) and $Cl^-$ (an inert gas structure). The susceptibility of the complex corresponds approximately to that of a single electron spin, and using Van Vleck's theory[1], this would be interpreted as arising from a hole in the $d_{xy}$, $d_{yz}$, $d_{zx}$ shell. Van Vleck shows how this result can be reached either by the directed valence bond, or the strong crystal field, or the molecular orbital approach; although in the molecular orbital method he only considers combinations between orbitals such as $d_{x^2-y^2}$, $d_{3z^2-r^2}$ (central ion) and $p_\sigma$ (attached ions). The experimental evidence in ammonium chloroiridate suggests that the magnetic hole is described by admixtures of $3p_\pi$ (Cl) orbitals with $5d_{xy}$, $d_{yz}$, $d_{zx}$ (Ir) orbitals. This can also be pictured as a mechanism whereby for part of the time an electron is transferred from $Cl^-$ to $Ir^{4+}$, cancelling the unpaired spin on the iridium, and leaving an unpaired spin on a chlorine atom.

In the paramagnetic resonance spectrum, this leads to two effects, both of which have been observed: (i) there will be a hyperfine structure from the chlorine nuclei, and (ii) the spectroscopic splitting factor will be smaller than $g = 2$, the value given by Van Vleck's theory. From the measured size of the hyperfine structure, and from the observed value, $g = 1 \cdot 8$, we have tentatively estimated that the electron hole is on a particular chlorine atom for about 3 per cent of the time, and on some chlorine atom for about 18 per cent. The paramagnetic resonance method thus gives a direct and quantitative measure of π-bonding, or, crudely, of the whereabouts of the electron hole.

Theoretical and experimental work is proceeding, and we hope soon to look for similar phenomena in other compounds, particularly potassium bromoiridate. All this work will be reported more fully in due course.

## Dielectric Relaxation Time of Polar Molecules in Solution

MEASUREMENTS of the dielectric relaxation time ($\tau$) of a polar substance ($B$) in a non-polar solvent ($A$) are usually interpreted in terms of the generalized Debye formula[1]:

$$\tau = (8\pi\eta_A a_B^3)/2kT, \qquad (1)$$

where $\eta_A$ is the viscosity of the solvent, and $a_B$ is the radius of the solute molecule.

A closer examination of the processes involved shows that this extension of Debye's formula to a solution is not justified, because $\eta_A$ is determined by the interaction between the solvent molecules, whereas $\tau$ is determined by the interaction between non-polar and polar molecules.

In a discussion to be published elsewhere, it is shown that, for a very dilute solution,

$$\tau = (A\eta_{AB})/2kT, \qquad (2)$$

where $A$ is a function of the moments of inertia and masses of the two types of molecule, and the intermolecular distances, and is of the same order of magnitude as $a_B^3$, and $\eta_{AB}$ is the 'mutual viscosity'

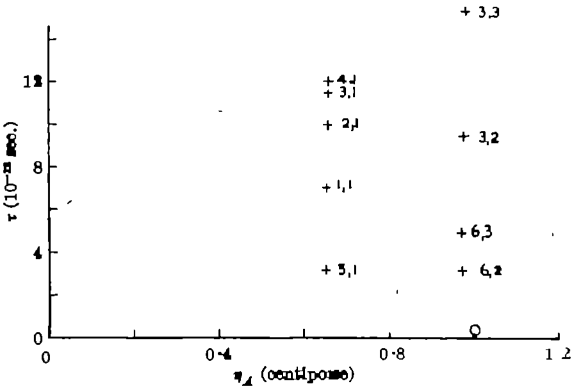

Fig. 1. Relaxation time and solvent viscosity. Numbers at points refer to solute and solvent respectively. Solutes: 1, phenyl chloride, 2, phenyl bromide; 3, phenyl nitrite; 4, phenyl propionate; 5, methyl acetate; 6, chloroform. Solvents: 1, benzene; 2, *cyclo*hexane; 3, carbon tetrachloride.
For the point marked by a circle, both scales should be multiplied by 200

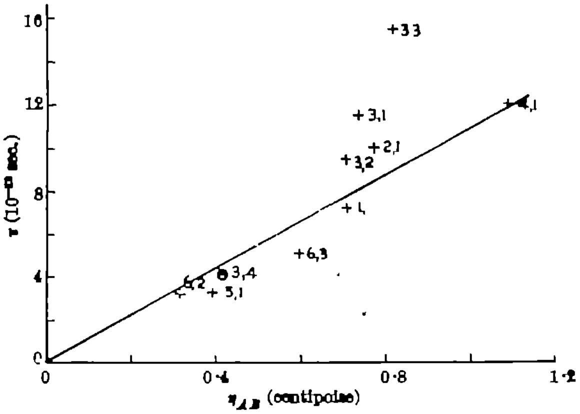

Fig. 2. Relaxation time and mutual viscosity. Numbers at points have the same significance as in Fig. 1. For the point marked by a circle both scales should be multiplied by 10

of the two substances, which can be found from the viscosity of the mixture, since

$$\eta\sigma = f_A^2\eta_A\sigma_A + f_B^2\eta_B\sigma_B + 2f_Af_B\eta_{AB}\sigma_{AB}, \qquad (3)$$

where the $f$'s are mole fractions, the $\sigma$'s are intermolecular distances, and terms without suffix refer to the mixture.

Relations (2) and (3) are derived using Andrade's[2] model of a liquid.

Figs. 1 and 2 show $\tau$ plotted as a function of $\eta_A$ and of $\eta_{AB}$ respectively for various polar solutes in benzene ($\eta$ = 0·65 c.poise), *cyclo*hexane ($\eta$ = 0·97 c.poise), carbon tetrachloride ($\eta$ = 0·97 c.poise) and medicinal paraffin ($\eta \sim 200$ c.poise). The relaxation times are taken from the results of Whiffen and Thompson[3], and of Curtis, McGreer, Rathmann and Smyth[4]. The values of $\eta_{AB}$ are deduced from data given in the "International Critical Tables" for solutes in benzene, and from measurements I have made in other cases.

From the graphs it can be seen that there is no simple relation between $\tau$ and $\eta_A$, as required by the Debye formula; but that the graph of $\tau$ against $\eta_{AB}$ does approximate to a straight line through the origin as required by equation (2). Deviations from the linear relation may be interpreted as reflecting variations of the function $A$ of the molecular sizes.

## A.C. Operation of Ion Chambers

MEASUREMENT of low-intensity ionization in an ion chamber involves the amplification of very small currents. D.C. operation is conventional; but it is difficult to provide stable valve amplification of a weak D.C. signal. Conversion to A.C. by a vibrating-reed gives good sensitivity and stability, but the mechanical device is elaborate. A.C. operation and amplification appears to be stable and simple, and is capable of high sensitivity.

The current produced by irradiation in the A.C. case is caused not primarily by the collection of ions but by the oscillation of a space charge within the chamber. This builds up slowly to its equilibrium density after a source of radiation is brought near the chamber, giving slow response time but high sensitivity. With the bridge circuit described for 10 c./s. operation, an irradiation sensitivity equivalent to $10^{-14}$ amp. D.C. may easily be obtained; the current rises to its maximum value with a time-constant of about ½ min.

Kiehn[1] has described a single ion-chamber in a Wien bridge operated at 150 c./s. The high frequency gives rapid response times but reduced sensitivity. The apparatus developed in the present investigation was designed for high-sensitivity measurements of strontium-90 – yttrium-90 bremsstrahlung radiation.

Two T.P.A. (gamma-sensitive) ion chambers, filled with argon at 20 atmospheres pressure, are connected in opposition as two arms of an A.C. bridge; each balance arm consists of adjustable capacity and parallel resistance. The bridge is fed with 10 c./s. at 24 volts. Out-of-balance current is detected by an amplifier with electrometer triode input; the amplified signal is led to a 'gate' pentode where it is filtered for both frequency and phase, and the smoothed anode current measured on the output meter. The bridge is easily balanced to eliminate all capacitive current through the ion chambers, and much of the cosmic background current as well. Irradiation of either chamber separately causes additional resistive current to flow in the chamber; the output meter shows a change in reading proportional to the radiation intensity over a small range. The sensitivity is limited by variations in the balanced background currents to a value of about 2 microcuries radium at 100 cm. from one chamber.

This work will be reported in detail elsewhere.

## Atmospherics with Very Low-frequency Components

THE low-frequency (c. 100–500 c./s.) or 'slow tail' component in the wave-form of an atmospheric was first studied in detail by Watson-Watt, Herd and Lutkin[1]. They defined two parameters: the delay $t$ as the time elapsing between the start of the main oscillatory section of the atmospheric and the commencement of the slow tail, and the quarter-period $\tau/4$ as the time occupied by the first quarter-cycle of the tail. Both $t$ and $\tau/4$ were found to increase in a somewhat irregular, non-linear, manner, as the distance of origin, $D$, of the atmospheric increased.

An extensive programme of observations of slow tails has recently been completed at the Cavendish Laboratory. Throughout the programme, the kind co-operation of the Meteorological Office "Sferics" Organization[2] has greatly enhanced the value of the work by locating the sources of individual wave-forms. Although it was noted that, for any estimated distance and any hour of the day, the individual values obtained for $t$ and $\tau/4$ showed considerable scatter, the results, when averaged, were found to be represented for distances up to 5,000 km. by two simple linear equations. With $t$ and $\tau/4$ in μsec., and $D$ in km.: $t = k(D - D_0)$, where $D_0 \sim 1{,}000$ km., and $\tau/4 = \tau_0 + cD$, where $\tau_0 \sim 500$ μsec.

The constants $k$ and $c$ have significantly different values by day and by night; in day-time, $k(d) = 0{\cdot}33$ and $c(d) = 0{\cdot}23$; at night, $k(n) = 0{\cdot}13$ and $c(n) = 0{\cdot}08$.

The transition from day-time to night-time was observed to occur gradually; the steady night-time conditions only became established some three hours after the latest time of ground sunset along the path of the atmospheric.

Many of the features in an atmospheric wave-form may be interpreted by examining the propagation of a primary pulse in the wave-guide formed by the earth and the lower boundary of the ionosphere[1]. This approach is especially applicable to low-frequency effects, since only one or two wave-guide modes, at most, are concerned, and Hales[4] has indicated how the slow-tail phenomena may be explained by considering propagation between a perfectly conducting earth and an ionosphere of finite conductivity. From the present results it is possible, on Hales's theory, to derive a range of solutions for $h$, the height of the ionospheric stratum involved, and $\sigma$ its conductivity; but neither can be determined separately. Estimates are, however, available from other sources for the electron and ion density and collisional frequency at various levels in the ionosphere, and hence for the variation of $\sigma$ with $h$, ignoring any effects due to the earth's magnetic field. Using these estimates, it is found that the slow-tail results by day indicate propagation between the earth and an equivalent, homogeneous, ionospheric layer of height 65 km. and conductivity $5 \times 10^3$ e.s.u.; at night the height of the layer is 90 km. and the conductivity $11 \times 10^3$ e.s.u.

It is hoped to publish a fuller account of this work elsewhere. This programme received financial assistance from the Department of Scientific and Industrial Research.

## Paper Chromatography of Phosphate Esters

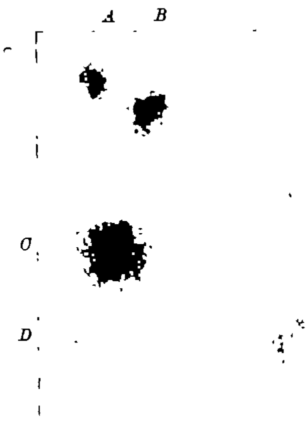
THE demonstration of phosphate esters on paper chromatograms has hitherto depended upon purely chemical methods for the liberation of the bound phosphate groups[1]. The specificity of these techniques might be a matter of some doubt and cause difficulties of interpretation when they are applied to chromatograms of unknown material obtained from a biological source. They also suffer from the disadvantage that the ease with which different organic phosphate esters are hydrolysed varies considerably, and the application of the method to esters which are not readily acid-labile, such as glucose-6-phosphate or phosphoglyceric acid, is sometimes uncertain[2].

In an attempt to overcome these deficiencies, we have developed an enzymic method, in which a solution of alkaline phosphomonoesterase, prepared by the method of Schmidt and Thannhauser[3], is used to liberate orthophosphate from the esters resolved on the chromatogram. The tendency for the resolved spots to spread and become diffuse when sprayed with the aqueous enzyme solution has been successfully countered by first spraying with a solution of calcium chloride in ethanol; any phosphate afterwards liberated on this impregnated paper at an alkaline $p$H is precipitated as insoluble calcium phosphate at the site of its liberation, and the compactness of the resolution is thus maintained. By this use of alkaline phosphatase, the paper chromatography of phosphate esters should gain both in specificity and in reliability of detection within the wide substrate range of the enzyme[3].

We have used Whatman No. 1 papers, 28 cm. square, washed for 10 hr. in 0·1 $N$ hydrochloric acid, then successively in running tap water and in distilled water, and finally dried at 70° C. The solvents used by Bandurski and Axelrod[4] and the two-dimensional development described by them were adopted with only slight modifications: formic acid was replaced by an equal volume of acetic acid in the acid solvent, and we usually ran our chromatograms in the basic solvent first.

After development by the two solvents, our procedure is as follows: the papers are thoroughly air-dried at room temperature, mounted on glass sheets slightly larger than the papers themselves, and sprayed with 10 ml. of a 5 per cent solution of $CaCl_2.6H_2O$ in 80 per cent ethanol. The ethanol is allowed to evaporate at room-temperature, and the papers are then sprayed with 10 ml. of the enzyme solution prepared in 0·1 $M$ glycine buffer at $p$H 9. (In our experiments the various enzyme solutions used liberated 50–200 μgm. phosphorus per ml. in 5 min. at 37° C. from an added excess of glucose-1-phosphate.) At this stage the papers are damp, but by no means saturated with solution; they are covered with a second sheet of glass, and the 'units', glass–paper–glass, incubated for 4 hr. at 37° C.

At the end of this time the papers, which are still damp, are firmly attached to their glass mounts and finely sprayed with 3 ml. of a solution of 5 per cent ammonium molybdate in 20 per cent hydrochloric acid (v/v). (Yellow phosphomolybdate spots quickly



Section of chromatogram showing resolution of: *A*, sodium glycerophosphate; *B*, 3-phosphoglycerate, *C*, glucose-1-phosphate; *D*, adenosine-5-phosphate appear where orthophosphate has been liberated in amounts equivalent to 1 μgm. phosphorus or more.) After standing for 2 min., the papers are further sprayed with 5 ml. benzidine solution (50 mgm. benzidine hydrochloride dissolved in 10 ml. glacial acetic acid and diluted with water to 100 ml.), using a fume cupboard with a good draught. They are then inverted over a trough of ammonia (sp. gr. 0·880, diluted 1 : 4) at a distance of 2 in. from the surface of the liquid, when the positions of liberated phosphate groups are shown by the appearance, within a minute, of bright blue spots which show distinctively on a white ground. 0·5 μgm. phosphorus is readily detected by this method. Over-exposure to ammonia at the final stage leads to rapid fading of the blue colour.

The accompanying photograph shows a resolution involving four typical phosphate esters: sodium glycerophosphate, 3-phosphoglycerate, glucose-1-phosphate and adenosine-5-phosphate.

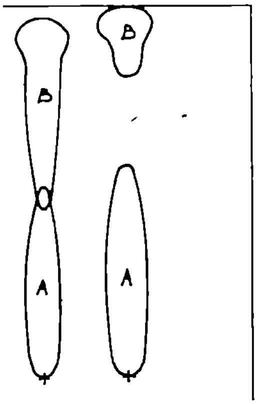
## Ion Exchange in Paper Chromatography

It has been shown by Schute that several mixtures of alkaloids can be separated by chromatography on paper using aqueous ammonia[1]. Because the chromatograms have the characteristics of a partition chromatogram, it is probable that the above separation is due to partition between an aqueous imbibition phase and an aqueous mobile phase.

It was also possible to show that, when the cellulose is not swollen (that is, it contains chemically bound water only) and the solvent is hexane, irreversible surface adsorption of alkaloids occurs[2]. An alkaloid can be displaced from the adsorbed state by a more polar one, and therefore it is probable that this adsorption is of a polar nature. Hence we may expect that the adsorption will decrease when the solvent becomes more polar. Moreover, when the cellulose is swollen by the solvent, an important part of the cellulose ceases to be a surface phase and becomes a volume phase. Surface adsorption on cellulose from a strongly polar and swelling solvent such as water is therefore very improbable.

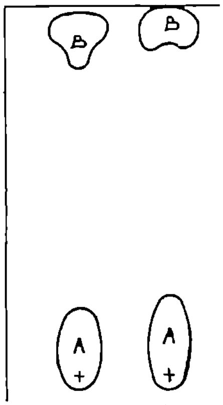
However, when acids and alkaloids are chromatographed on paper with water as a solvent, irreversible 'absorption' takes place. It can be shown that this is caused by ion exchange. When an aqueous solution of an acid (*HZ*) is in contact with paper, the hydrogen ions of the acid exchange with the cations ($M_p^+$) of the paper: $HZ \rightleftarrows H^+ + Z^-$ and $H^+ + M_p^+ \rightleftarrows H_p^+ + M^+$. Here $M_p^+$ represents ions of sodium, potassium, calcium, magnesium, etc., bound on carboxyl groups, silicate and other 'insoluble material'.

As the combination $M^+ + Z^-$ is chromatographed further and $H^+$ cannot be eluted from $H_p^+$ by pure water, the $H^+$ and $Z^-$ of the acid can be completely separated (Figs. 1 and 2). When the acid-spot *A* is separated from the salt-spot *B*, the area of *A* gives a measure of the total amount of exchangeable cation $M_p^+$. This amount is greater for the Schleicher and Schull paper than for the Whatman paper.



(a) (b)

Fig. 1



(a) (b)

Fig. 2

Chromatograms (Fig. 1, Whatman No. 1 paper; Fig. 2, Schleicher and Schull No. 1101 *L* paper) of 20 μgm. salicylic acid (*a*) and sulphosalicylic acid (*b*) developed with water. *A*, acid-spot visible after spraying with neutralized methyl red; *B*, salt-spot sprayed with ferric chloride, +, place of initial spot

When blank paper is chromatographed with water, electrolyte is eluted and the solvent contains cations, the concentration of which increases with the distance covered by the front. Because the $H^+$ is exchanged from the $H_p^+$ area by this electrolyte, the rear boundary of this area is removed farther from the initial spot, when this spot has been placed farther from the base. This phenomenon disappears almost completely when the paper is first washed 'chromatographically' with water. However, when washed paper is chromatographed with water for a second time, electrolyte is eluted again from the paper. This may be explained by the reaction:

$$M_p^+ + H_2O \rightleftarrows M^+ + OH^- + H_p^+,$$

a hydrolysis corresponding to the 'membrane hydrolysis' of Donnan, as suggested by Hirsch[3]. Thus, in washed paper, part of the exchangeable cation has already been displaced by hydrogen ion, and this agrees with the fact that the area of the acid spot increases on washing the paper with water. This must be taken into consideration when we wish to determine the amount of $M_p^+$ by measuring the acid area.

In Fig. 1 the front part of the acid spot from salicylic acid contains salicylate. In this part there is still unchanged salicylic acid, and it appears that this acid travels much more slowly than the solvent front ($R_F$ about 0·5).

When the paper is washed 'chromatographically' with hydrochloric acid and next with water to remove the excess of acid, all exchangeable $M_p^+$ is displaced by $H^+$ ($H^+$ paper). When salicylic and sulphosalicylic acid are chromatographed with water on this $H^+$ paper, normal chromatograms occur and both acids are separated, the $R_F$'s being about 0·55 and 0·70 respectively when Whatman No. 1 paper is used.

As ion exchange on this paper is impossible and surface adsorption highly improbable, we may conclude that the separation in this case is caused by partition between imbibition water and mobile water, the imbibition water having properties other than pure water.

When an alkaloid (*XN*) is chromatographed, ion exchange is possible:

$$XN + H_2O \rightleftarrows XNH^+ + OH^- \quad \text{and}$$
$$XNH^+ + M_p^+ \rightleftarrows M^+ + XNH_p^+.$$

When $H^+$ paper is used, direct salt formation will occur:

$$XN + H_p^+ \rightarrow XNH_p^+.$$

It appears that $XNH_p^+$ is only slightly eluted by pure water, and this gives another possibility of estimating the amount of $M_p^+$, displacing first the $M_p^+$ by $H_p^+$ and measuring the area of an alkaloid bound by the $H_p^+$.

The alkaloid ion in $XNH_p^+$ will be exchanged for cations. When the cation is another alkaloid ion which is bound preferentially, the two alkaloids can be separated; hence mixtures of alkaloids can be analysed by ion exchange on paper with water as a solvent.

It is clear that ion exchange will also occur when the mobile phase is an organic solvent and the stationary phase is an ionizing medium such as water. It is probable that many of the abnormalities occurring in paper chromatography of ionizable substances may be explained, at least partly, by this ion exchange. This is supported by the fact that abnormalities in the chromatography of alkaloids are decreased by impregnating the paper with potassium chloride, as is found by Munier *et al.*[4]. The excess of electrolyte in the stationary phase will make the $XNH_p^+$ bonding impossible.

This investigation is part of a study of the mechanism of paper chromatography, full reports of which will be published in due course. I thank Prof. E. H. Vogelenzang for his interest and encouragement, and the Dutch Organization Z.W.O. for financial support.

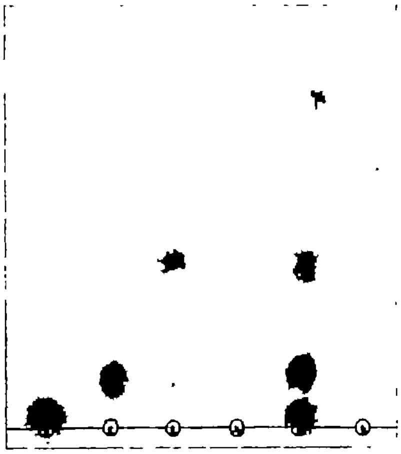
## Paper Chromatography of Thioureas

IN the course of a current investigation, it became necessary to separate and identify minute amounts of N-substituted thioureas. Paper chromatography suggested itself as the method of choice for this purpose, and a technique has now been worked out which gives satisfactory and reproducible results on some thirty thioureas investigated, separately or in complex mixtures.

As a result of numerous experiments, water-saturated chloroform was selected as the most satisfactory mobile phase. One-dimensional, ascending chromatograms were run on No. 1 Whatman paper at 23·5° ± 0·1°. The attainment of equilibrium in the chromatographic system presented some preliminary difficulties owing to the high density of the chloroform vapour. This problem was solved, however, by lining the glass walls of the chamber with filter paper soaked in chloroform and water. After equilibration of the sheets (17·5 cm. × 28·5 cm.) for 16–18 hr., the chloroform was allowed to rise 23·0 cm. from the starting line in the course of 110–120 min. Periods much outside this range were indicative of imperfect equilibrium and resulted in less satisfactory results. After development, the air-dried paper was sprayed with Grote's reagent[1] and, upon moderate heating, the thioureas appeared as distinct, deep-blue spots, gradually fading within a day or two. Comparable results were obtained by Feigl[2] on consecutive spraying with a starch solution and the iodine–azide reagent. In this case the thioureas appeared as colourless spots on a uniformly blue background. Owing to a slightly higher sensitivity of Grote's reagent, it was generally preferred throughout the present work.



Chromatogram of N-substituted thioureas developed with Grote's reagent. The substances were applied along the lower line as spots, each containing 0·002 ml. of a 1·0 per cent solution in ethanol. (1) Methyl, (2) ethyl, (3) *n*-propyl; (4) phenyl, (5) a mixture of methyl-, ethyl-, *n*-propyl, *n*-butyl and phenyl-thiourea, applied as 0·002 ml. of an ethanolic solution containing 1·0 per cent of each component, (6) *n*-butyl

Even under carefully controlled conditions, some variations in the $R_F$-values were noticed from one run to another. These fluctuations could be eliminated by including N-phenylthiourea as a reference substance in every run and considering the movement in relation to this arbitrary standard. For convenience, we have introduced the term $R_{Ph}$-value, defined as the ratio between the distances travelled by the individual component and phenylthiourea. The $R_{Ph}$-values were found to be reproducible within ± 0·01. In the accompanying table, results are presented for a few typical mono-substituted thioureas. Di-, tri- and tetra-substituted thioureas were also successfully separated; but S-substituted *iso*-thioureas did not respond to Grote's reagent. A series of thiobarbituric acids were separated and detected as yellow spots on spraying with the same reagent. However, Grote's reagent proved to be unsuitable for the detection of thiosemicarbazides owing to the varying and often transient nature of the colours produced.

| N-Substituent(s) | $R_{Ph}$-values |
|---|---|
| Methyl | 0·04 |
| Ethyl | 0·15 |
| *n*-Propyl | 0·48 |
| *n*-Butyl | 0·84 |
| Allyl | 0·26 |
| Benzyl | 0·90 |
| *sym*.-Dimethyl | 0·41 |
| Trimethyl | 1·22 |

Separations of mixtures containing individual components with $R_{Ph}$-values higher than c. 1·20 were often facilitated by using the slow No. 50 Whatman paper.

A fuller account of the work will be published in *Acta Chemica Scandinavica*.

## Use of Ion-Exchange Resins in Paper Chromatography of Sugars

THE recent communication by Phillips and Pollard[1] suggests that results obtained here may be of interest. In the paper chromatography of dilute and very impure sugar solutions, such as non-diabetic urines or certain protein hydrolysates, it is common practice to use beforehand a 'mixed bed' ion-exchange resin to remove interfering anions and cations[2]. For example, 'Bio-Deminrolit E', a mixture of a weakly basic resin containing amine groups and a sulphonic acid type resin, is shaken with the solution for 20 min. and, after centrifuging, the clear supernatant contains all the sugars (except amino-sugars and uronic acids) uncontaminated by ionizable substances[3]. When 'Bio-Deminrolit E' was replaced by 'Bio-Deminrolit' or 'Bio-Deminrolit F', which are mixtures of sulphonic acid type resins with strongly basic resins of the quaternary ammonium hydroxide type, it was found that all fructose, glucose, galactose, mannose and fucose were removed from the dilute solutions employed.

The effect was investigated using columns 1 cm. diameter and 2–5 cm. long of 'Amberlite IRA400' (OH form), and it was found that 2 mgm. of glucose, for example, was completely removed from solution by such a column and, with the quantity used, none or at most 10 per cent of the sugar was recoverable by immediate elution with dilute hydrochloric acid. Of the sugars investigated glucosamine[4], galactosamine and N-acetylglucosamine were anomalous in that, while they were completely removed by the resin, they were recovered quantitatively by hydrochloric acid elution. Non-reducing sugars were not investigated.

If 'Bio-Deminrolit' is saturated with carbon dioxide, the quaternary ammonium bicarbonate is formed. The resulting mixed resin is used in this laboratory in place of 'Bio-Deminrolit E' (now unobtainable) and is very satisfactory. There was no appreciable loss of fructose or glucose from a dilute solution of the sugars left over 'Bio-Deminrolit' ($HCO_3$' form) for nine days at 0 °C.

I wish to thank Mr. J. D. Cheshire and Miss S. D. Birchenough for technical assistance.

## Separation and Structural Determination of the Olefinic Components of Poison Ivy Urushiol, Cardanol and Cardol

THE noxious saps of numerous members of the Anacardiaceæ, such as Japanese lac, poison ivy, cashew nut shell liquid, etc., contain phenolic bodies carrying long unsaturated side-chains attached to the benzene ring. Earlier investigators[1] have in certain cases established the length and the position of these alkenyl side-chains; but prior to the present investigation only very limited information was available concerning the structural details of the unsaturation. There is no doubt, however, that the unsaturation in the side-chain plays an important part both in the physiological properties[2] and industrial uses[3] of these compounds.

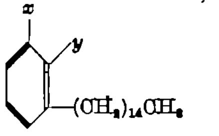
To explain the formation of a variety of oxidative degradation and ozonolysis products, Majima[1] concluded that Japanese lac urushiol is hetero-olefinic in character. He proposed structures for mono-, di- and tri-olefinic components; but he was not able to separate these components for their decisive structural identification. In fact, work now in progress in these laboratories[4] indicates that two of the structures proposed by Majima will have to be modified.

Earlier investigations[5] in this laboratory have established that the alkenyl phenols, anacardic acid and cardanol (also called anacardol[1]) obtained from the shell liquid of the cashew nut are also hetero-olefinic in character. However, no evidence has been available concerning the olefinic heterogeneity of cardol, the resorcinol component largely responsible for the dermatitis caused by cashew nut shell liquid[6].

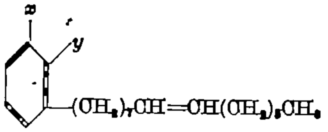
Most of the interest in the United States in regard to the physiological properties of these alkenyl phenols has been focused on poison ivy. The difficulty of obtaining the toxic phenol in pure form from the poison ivy sap has seriously hampered efforts to gain more information about its unsaturated character. Poison ivy urushiol absorbs hydrogen equivalent to about two double bonds and is converted into 3-pentadecylcatechol[1b]. Although Mason and Schwartz[7] concluded on the basis of preliminary chromatographic experiments that at least three toxic components are present in poison ivy urushiol, they did not separate these components in a form suitable for structural elucidation.

By means of chromatographic adsorption of the methyl ethers of three of these alkenyl phenols (poison ivy urushiol, cardanol and cardol) on alumina, we now have been able to separate the different olefinic components in pure form. In the case of poison ivy dimethyl urushiol, four components have been isolated—one of which had a completely reduced side-chain and the other three possessed one, two and three double bonds. Each of the three olefinic components absorbed the theoretical amount of hydrogen on catalytic reduction and yielded in pure form the saturated component (3-pentadecylveratrole). The structures of the four components of poison ivy urushiol now established on the basis of the products isolated from ozonolysis and oxidative degradation involving the dimethyl ether are shown in the accompanying formulæ (p. 842).

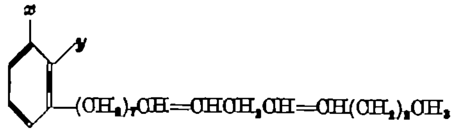
Cardanol, the monophenol obtained from the cashew nut shell liquid, was found to absorb hydrogen equivalent to about two double-bonds. Its methyl ether was also separated into four chromatographically pure components, the side-chains of which proved to be identical with those of the corresponding



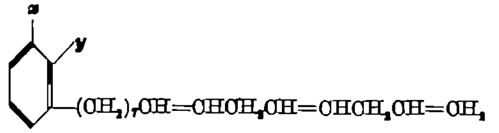
(I)



(II)



(III)



(IV)

Components of poison ivy urushiol ($x = y =$ OH)

components of poison ivy urushiol. The structures of the pure components of cardanol, therefore, can be represented as I, II, III and IV, respectively, where $x$ = OH and $y$ = H.

Anacardic acid, the alkenyl salicylic acid component of cashew nut shell liquid, also absorbs two moles of hydrogen and is hetero-olefinic. On reduction it is converted into 2-carboxy-3-pentadecylphenol. Since anacardic acid gives cardanol on smooth decarboxylation, it seems probable that the hetero-olefinic character of anacardic acid can be explained in terms of olefinic components corresponding in structures to those found in cardanol (I, II, III and IV; $x$ = OH, $y$ = COOH).

Cardol, the toxic resorcinol component of cashew nut shell liquid, usually absorbs somewhat more than two molar equivalents of hydrogen and is converted into 1,3-dihydroxy-5-pentadecylbenzene. It was found to be composed mainly of a diolefin and a triolefin having alkenyl side-chains identical with those shown above.

No component having more than three double bonds could be detected in any of the three alkenyl phenols investigated.

A detailed account of this work will be reported elsewhere. We are indebted to the Lederle Laboratories Division of the American Cyanamid Company for a grant supporting this investigation. An extract of poison ivy was also supplied by the Lederle Laboratories. The cashew nut shell liquid was kindly supplied by the Irvington Varnish and Insulator Company.

## Specific Volume of Cellulose in Aqueous Solutions of Inorganic Salts

THE specific volume of cellulose (sheet viscose) in aqueous solutions of ammonium, sodium and potassium chlorides, at 25° C., has been measured, using a 'hydrostatic balance', for the whole of the solubility range of the salt.

The curve obtained in the plot of specific volume against concentration passes through a maximum in each case. The concentration of the external solution at the maximum specific volume for each salt is:

| Salt | Concentration (wt. per cent) |
|---|---|
| Ammonium chloride | 14·3 |
| Sodium chloride | 18·0 |
| Potassium chloride | 16·0 |

Calculation of the ratio of gram molecules of water per gram cation at this concentration, assuming equal hydration of anion and cation in all cases, gives the following values:

| Ion | Ratio |
|---|---|
| $NH_4^+$ | 8·9 |
| $Na^+$ | 7·5 |
| $K^+$ | 11·6 |

From the effective radius of the ion[1] and of the water molecule, the number of water molecules which can be arranged around each ion, from purely geometrical considerations, may be calculated:

| Ion | Radius (A.) | 'Geometrical' number of water molecules |
|---|---|---|
| $NH_4^+$ | 1·42 | 12·0 |
| $Na^+$ | 0·95 | 7·5 |
| $K^+$ | 1·33 | 12·0 |
| $H_2O$ mol. | 1·38 | 12·0 |

The following suggestion is offered in explanation of the specific volume curve.

There is evidence[2] for believing that, in the initial stages of water adsorption by cellulose, the water is under a compressive force, causing it to have a density greater than ordinary liquid water.

Addition of a salt provides polar centres which disorganize the water atmosphere, and has a decompressing effect on the adsorbed water layer. The specific volume of the cellulose therefore increases with increasing salt concentration, until the activity of the water in the system is so reduced that it is unable to satisfy the hydration requirements of the ions. Further addition of salt then results in direct linkage of the salt ions with the cellulose, and the specific volume decreases once more.

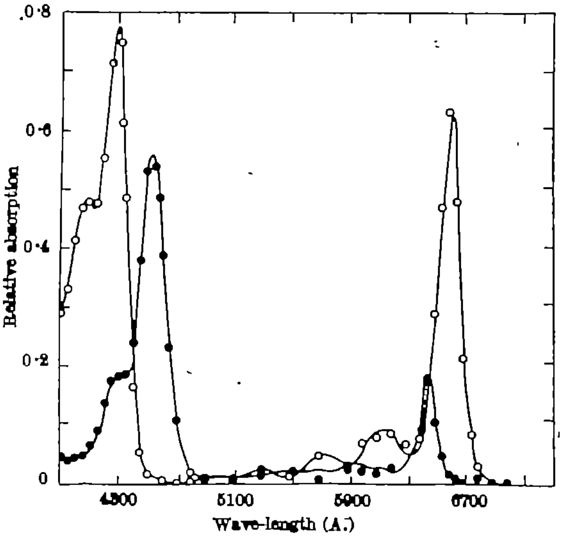
## Absorption Spectra of the Ethyl Chlorophyllides

THE spectra of the ethyl chlorophyllides, the crystalline derivatives of chlorophyll by replacement of the phytyl by the ethyl radical, are of interest as these compounds are valuable as actinometry standards in the study of the efficiency of photosynthesis. No report seems to have been made of



Absorption spectra of the ethyl chlorophyllides in ether. Solid lines, absorption spectra of chlorophylls *a* and *b*, from Harris and Zscheile (ref. 2), open circles and filled circles, relative absorption coefficients for ethyl chlorophyllides *a* and *b* respectively

their absorption spectra, except for some indirect evidence that they are different from those of the chlorophylls[1].

This has now been tested directly. A sample of the mixed chlorophyllides, which had originally been prepared by A. Stoll, was kindly supplied by Dr. J. Weiss. This sample was dissolved in petroleum ether and chromatographed by the method employed for the chlorophylls[2]. A dark residue remained within ½ mm. of the top of the column. This probably accounts for part of the spectral results previously obtained. The two bands of the chromatogram were twice re-chromatographed.

The spectra of the two chlorophyllides in ether and methanol were measured using a Beckman spectrophotometer. These spectra could then be superimposed exactly on the corresponding chlorophyll spectra[2] on adjustment of the absorption coefficients at one point, as is illustrated in the diagram. An attempt was made to obtain the absolute extinction coefficients by direct weighing after extracting the dissolved sugar with water. This was unsuccessful, as the chlorophyllides were altered in spectra by this treatment. Despite the lack of the absolute extinction coefficients, the identity of spectral shape leaves little doubt that the spectra of the ethyl chlorophyllides are the same as those of the corresponding chlorophylls.

This work is part of a study of chlorophyll *in vitro* being carried out under the direction of Prof. R. Livingston, of the University of Minnesota, and supported by the U.S. Office of Naval Research (Contract N6 ori—212).

## Electrolytic Polishing of Lead in a Sodium Acetate – Acetic Acid Bath

In the course of experimental work on the anodic behaviour of lead, it was found desirable to produce a high degree of polish on specimens which might have overall areas of as little as 1 sq.cm. An examination of the literature indicated that the recommended bath for polishing this metal was one consisting of 250 c.c. of 60 per cent perchloric acid, with 750 c.c. glacial acetic acid. We considered that, because of the intermittent use that would be made of the solution, it would be unpleasant to store; a search was therefore made for alternatives. The experiment was tried of increasing the conductance and buffer capacity of glacial acetic acid by the addition of sodium acetate, and the present note gives details of useful operating conditions for electrolytic polishing in the resultant solution.

For most of our experimental work, we employed cylindrical lead specimens, about 1 cm. in diameter and mounted with the exposed face vertical. The electrical connexion to the back surface, and also this surface, were coated with a thermal-setting insulating varnish. A graphite or platinum cathode was placed about 5 cm. away from the anode. Contrary to normal practice the current, rather than the applied voltage, was controlled, and by this means the specimen could be etched or polished. Polishing occurred at current densities between 50 and 100 mA./cm.$^2$ in a bath of the following composition:

| | |
|---|---|
| Anhydrous sodium acetate | 60 gm. |
| Glacial acetic acid | 315 c.c. |
| Water | 80 c.c. |

The over-potential at the anode has been measured by means of a Luggin capillary and saturated calomel electrode, and a value of 4–5 V. was recorded during polishing. Polishing occurred in the following stages on the 1-cm. diameter specimens: (*a*) etching; (*b*) polishing began at the edges, working inwards across the surface, followed by the inward growth of a film; (*c*) after about two minutes, this film completely covered the surface, the over-potential reaching a maximum value; oxygen was not evolved; (*d*) patches of polish began to show, and after four minutes a highly reflecting surface appeared which was maintained on continuing to pass the current.

If the current is interrupted for a few seconds, on re-starting the above cycle is repeated, etching being first produced on the smooth surface.

## Natural Origin of Optically Active Substances and Optical Resolution by Symmetric Agents

The communication by R. C. Ferreira[1] stresses the implications of his findings (and those of H. M. Powell[2]) on the origin of 'molecular dissymmetry' in living matter through nucleation of a saturated solution of an externally compensated compound by a crystal containing an excess of one enantiomer. Possibly certain earlier work bearing upon the same fundamental principle runs some danger of being overlooked. It was observed more than a hundred years ago[3] that a solution of externally compensated ammonium hydrogen malate upon evaporation deposited crystals containing about three parts of the (−)-salt to one part of the (+)-salt, showing that a partial spontaneous resolution had taken place.

A remarkable susceptibility to nucleation was recorded by Anderson and Hill[4], who showed that when optically inactive atropine sulphate was crystallized in a laboratory in which the (−)-form had been racemized, the first crop was almost invariably (−)-rotatory, owing to inoculation from the atmosphere. It has even been established that effective nucleation of this kind may be brought about by crystals composed of *symmetric* molecules. In 1908, Ostromisslensky[5] described the optical resolution of externally compensated asparagine through nucleation with crystals of glycine, $CH_2(NH_2).COOH$, as follows: "Beim Impfen der übersättigten wässrigen *d,l*-Asparaginlösungen mit vereinzelten Glykokollkrystallen scheidet sich bald die rechte, bald die linke Antipode aus. Es ist in diesem Falle nicht möglich vorauszusehen, welche der beiden Antipoden ausgeschieden wird, weil die Hemiedrie des Glykokolls nur in vollständig versteckter Form auftritt".

The bearing of such phenomena upon the origin of optically active organic substances in Nature was expressed, for example, in 1926, as follows[6]: "A solution of a substance susceptible to spontaneous separation dries up by natural evaporation and deposits a conglomerate of the two kinds of crystals. One of these crystals is introduced fortuitously into an adjacent supersaturated solution of the substance. It is known that under such conditions a crystalline separation may occur of the optical isomer similar to the inoculating crystal. Imagine at this point that the mother-liquor is drained from the crystalline deposit by a further natural process. Two optically active nuclei are now available, namely, the crystalline separation and the substance remaining in the mother-liquor".

## Repetitive Post-Synaptic Discharge in a Sensory Nucleus

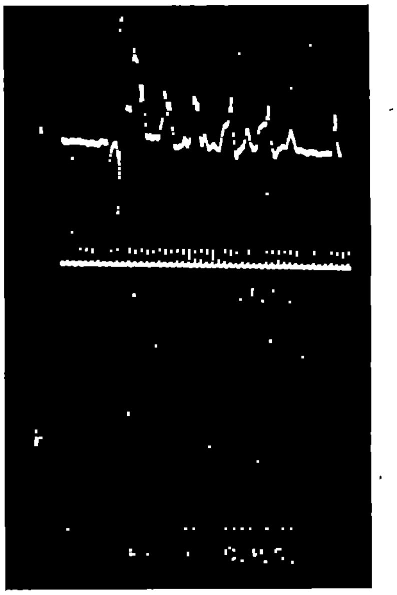
In the course of an investigation into the mechanism of synaptic transmission in the dorsal nucleus of the lateral geniculate body of the cat, the phenomenon of repetitive firing by the ganglion cells has been repeatedly observed following a brief electrical stimulus to the optic nerve.

Extensive electrophysiological studies in this laboratory have shown that the optic nerve and tract contain two groups of fibre sizes. This is clearly shown when only the crossed or uncrossed components of the optic tract are stimulated separately. The fibre groups in the crossed pathway, however, conduct somewhat more slowly than the corresponding groups in the path that remains uncrossed at the chiasm. This fact tends to obscure a clear-cut demonstration of the two groups in the fibre-size spectrum of the optic nerve. The form of the compound action potential of the optic nerve and its relation to the fibre-size spectrum will be reported in detail elsewhere.

By electrical stimulation of the optic nerve, it is possible to activate the group of large-diameter fibres in the opposite tract without significantly affecting the smaller-diameter fibres. In these circumstances a micro-electrode within the corresponding lateral geniculate records the typical waveform shown in record (*b*). It has been shown to consist of an initial positive negative diphasic wave (1) representing the arrival of impulses along optic tract fibres, followed after a short delay by post-synaptic activity leading to the discharge of impulses along optic radiation fibres. The post-synaptic discharge (2) has been shown to consist of a negative positive diphasic radiation spike superimposed upon and initiated by a negative synaptic potential. This wave (2) may be termed the primary post-synaptic response; but in most preparations it may be seen to be followed after a delay of 2–4 m.sec. by another negative wave which represents the beginning of the secondary response. The latter is attributed to repetitive firing or after discharge on the part of the optic radiation neurones.

Record (*a*) shows the same response on a slower time-base sweep. As many as ten distinct secondary spikes have been seen, and they occur at fairly regular intervals of 1·5–3·0 m.sec. The repetitive discharge is prevented, without significantly affecting the primary response, by increased rate of stimulation (greater than 2 per sec.), increased depth of anaesthesia (dial or nembutal) or by mild asphyxia.

The spikes of the secondary response are frequently clearly diphasic, negative positive, and appear to arise out of a synaptic potential. This similarity in form to the primary response suggests that the spikes



(*a*) Repetitive firing by the cells of the contralateral lateral geniculate body following a single optic nerve stimulus. These records were obtained from an intrageniculate recording site with only the group of larger-diameter optic nerve fibres stimulated
(*b*) The same phenomenon recorded from a different position in the lateral geniculate using a faster time-base sweep

represent impulses discharged along optic radiation fibres.

Repetitive firing has been previously reported in sympathetic ganglia[1] and in motoneurone pools[2]. The repetitive firing in the lateral geniculate is not related to the former, for in sympathetic ganglia the phenomenon is not observed unless the ganglia are conditioned by a tetanus of at least 50 stimuli per sec., whereas in the case of the lateral geniculate it is prevented by a stimulation-rate greater than 2 per sec. The phenomenon is probably due to internuncial activity, which also forms the basis of the after-discharge from motoneurone pools. It is suggested that in the lateral geniculate the discharge is the result of the activity of a large number of relatively simple reverberating circuits arranged in parallel array, each possessing an optic radiation neurone and one or more interneurones.

Histological studies provide good evidence for the existence of short axon cells in the lateral geniculate, and recurrent collaterals from optic radiation neurones have been described. It appears that repetitive firing by the lateral geniculate is a normal response under these experimental conditions. The observations of Lloyd and McIntyre on the gracile and cuneate nuclei[3] make it likely that repetitive firing is a property of these nuclei also. These findings suggest a more important role for the sensory nuclei in the organization of sensory impulses than is generally supposed.

This investigation was aided by grants from the National Health and Medical Research Council of Australia and the A. E. Kahn Donation.

## Vitamin $B_{12}$ Content of Calf Thymus Extract

THYMUS and thymus extracts have been reported by Asher[1], Rowntree, Clark and Hanson[2], and others using rats as test animals, to have a growth-stimulating effect. Later experiments did not confirm this observation[3,4]. The conflicting results may have been due to deficient diet given to the control animals of the earlier investigators[4], or to the varying value of the calf thymus extracts used. No generally accepted explanation, however, has been found for the growth results. Hammar[5] was of the opinion that some vitamin of the B group may be a contributing factor.

The necessity of an animal protein factor for the growth of several animals has been proved in recent times. This animal protein factor has been regarded as either identical with vitamin $B_{12}$ or as containing vitamin $B_{12}$. In rats, the growth-stimulating effect of vitamin $B_{12}$ appears so distinctly that their growth is employed as an assay method for this vitamin[6].

We have endeavoured to determine the vitamin $B_{12}$ content of a calf thymus extract used in growth experiments[2-4]. The thymuses were taken from freshly slaughtered calves and preserved deep-frozen. The calves were classified into three age groups: 2–4 weeks, 3–4 months and more than 6 months old. The first two groups had been on a milk diet, whereas the third had received ordinary vegetable food. 600 gm. of thymus per litre was used in each group for the preparation of the extracts. The extracts were made according to the method introduced by Hanson[7]. The vitamin $B_{12}$ content of the sterile extracts filtered in a Berkefeld filter was determined with mutant *E. coli* strain 113–3 by the serial dilution method. The composition of the nutrient medium was as follows[8]: $K_2HPO_4$, 7·0 gm.; $KH_2PO_4$, 3·0 gm.; $Na_3$.citrate.$3H_2O$, 0·5 gm.; $MgSO_4.7H_2O$, 0·1 gm.; $(NH_4)_2SO_4$, 0·1 gm.; glucose (autoclaved separately), 10·0 gm.; and water, 1,000 gm.

The thymus extract of calves 2–4 weeks old contained 0·01 μgm. per ml. of vitamin $B_{12}$, that of calves 3–4 months of age contained 0·04 μgm. per ml. and the thymus extract of calves more than six months old contained 0·01 μgm. per ml. of vitamin $B_{12}$.

According to our results, the vitamin $B_{12}$ content in thymus extracts is such that it can have a growth-promoting effect if the basal diet has been deficient as regards vitamin $B_{12}$. Hence, the vitamin $B_{12}$ content of thymus may play a part in growth results obtained with thymus extracts.

## Effect of Dietary Penicillin on Blood Composition and Œstrogen-induced Oviduct Growth in the Folic-Acid Deficient Chick

STUDIES designed to elucidate the processes responsible for the growth-promoting effects of dietary antibiotics have shown that the growth-rate of chicks and rats deficient in individual vitamins is increased by addition of an antibiotic. Growth responses to antibiotics on adequate diets have also been shown to be accompanied by increases in blood and liver concentrations of certain vitamins[1]. It has been pointed out by Coates *et al.*[2] that such increases may be non-specific to antibiotic treatment and may merely accompany a growth acceleration. Common *et al.*[3] demonstrated an increase in the blood levels of calcium and riboflavin in œstrogen-treated pullets as a result of adding aureomycin to an adequate diet. On the basis of experiments by Hertz *et al.*[4] such an increase could be attributed to an increase in dietary availability of these nutrients. In view of these remarks concerning the difficulty in interpreting such increases in blood- and tissue-levels of a particular metabolite resulting from the inclusion of an antibiotic which also causes a growth stimulation, the two criteria of folic acid availability chosen in the experiment reported here were end-organ response to œstrogen and hæmoglobin-level in the blood. A short period of œstrogen treatment affects both blood composition and oviduct growth-rate, and the latter has been shown to be specifically reduced by folic-acid deficiency[4].

For the experiment eighty Light Sussex female chicks were reared for two weeks on a commercial chick mash and then placed on a purified folic-acid deficient diet similar to that of Lillie and Briggs[6], with the addition of vitamin $B_{12}$ ('Distivit') at a level of 5 μgm./100 gm. The chicks were maintained on this diet for two weeks and then allocated at random to two groups of equal number and balanced for live-weight. One of these groups was fed procaine penicillin at a level of 20 mgm./kgm. diet for a further period of seven days, while the other group was maintained on the control diet. Both groups were offered the same amount of food, which they consumed completely. The chicks in each group were then weighed individually and allocated at random to three groups, each of twelve chicks, for hormone and folic-acid treatment over a further period of four days. The treatments given to the three groups on the control and the penicillin diet are shown in the accompanying table. Each group consumed the same amount of food daily, and during this time folic acid and œstradiol dipropionate were given by intramuscular injections on the first and third days at the levels shown.

| Group | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| No. of chicks | 12 | 12 | 12 | 12 | 12 | 12 |
| Final body weight (gm.) | 611 | 617 | 620 | 624 | 615 | 617 |
| Procaine penicillin (mgm./kgm. diet) | Nil | 20 | Nil | 20 | Nil | 20 |
| Œstradiol dipropionate (mgm.) | Nil | Nil | 2×2·0 | 2×2·0 | 2×2·0 | 2×2·0 |
| Folic acid (mgm.) | Nil | Nil | Nil | Nil | 2×0·5 | 2×0·5 |
| Hæmoglobin (gm./100 ml.) | 8·72 | 9·70 | 9·41 | 10·35 | 10·43 | 10·54 |
| Oviduct weight (gm.) | 0·088 | 0·095 | 1·876 | 2·161 | 2·818 | 2·898 |
| Serum riboflavin (μgm./ml.) | — | — | 0·29 | 0·65 | 0·19 | 0·44 |
| Significance of difference between penicillin and control groups: Hæmoglobin | $P < 0.01$ | | $P < 0.001$ | | Not significant | |
| Oviduct weight | Not significant | | $P < 0.05$ | | ,, | |
| Serum riboflavin | — | | $P < 0.01$ | | $P < 0.05$ | |

The results show that the inclusion of penicillin in the deficient diet was accompanied by significant increases in hæmoglobin-levels in the blood of both control and œstrogen-treated chicks. The significant increase in the weight of oviduct of the chicks in group 4 as compared with group 3 is in agreement with this observation. Such increases in the weight of oviduct resulting from folic acid supplementation, as in groups 5 and 6, have been shown by me to be paralleled by an increase in dry weight and nitrogen content.

The higher serum riboflavin content of the penicillin-treated chicks receiving œstrogen confirms the observation of Common *et al.*[3], and shows that such changes in blood composition as a result of œstrogen treatment are unrelated to the specific failure of end-organ response attributable to a deficiency of folic acid. It would seem from this experiment that the addition of penicillin to the diet can result in a functional increase in folic-acid activity, as judged by the criteria cited above.

I am indebted to the Distillers Company (Biochemicals), Ltd., for the gift of procaine penicillin and vitamin $B_{12}$.

## Adsorption and Hæmolytic Action of Diacetyldeoxycholate

In an investigation of the relation of the hæmolytic activity of sodium cetyl sulphate and sodium lauryl sulphate to their adsorption to red blood cells, we found that hæmolysis only starts when a minimum quantity of the detergent is really fixed to the cell walls[1,2]. On the assumption that such hæmolysis does not necessarily involve a unique mechanism, we undertook the study of the relationship between hæmolysis and adsorption for a bile acid derivative.

Ponder[3] concluded from his experiments that sodium taurocholate reacts with some definite component of the cells which is solubilized, but that the lysin is not bound to the walls. After equilibrium it was found that the sodium taurocholate concentration, which was estimated colorimetrically, had remained constant, but the hæmolytic activity of the supernatant fluid had decreased enormously. We determined by the same technique the adsorption of radioactive deoxycholate, which was obtained by acetylation of deoxycholic acid with anhydric acetic acid labelled with carbon-14. A dilution series of the labelled lysin with borate buffer (*p*H 7·4) and a constant number of red cells ($7 \times 10^{9}$ in a total volume of 8 ml., bovine blood) were separated by centrifugation after four hours. The distribution of the deoxycholate was estimated both in the red cells and in the solution by measuring its specific activity, and the rate of the hæmolysis was recorded (Table 1).

Adsorption in this case is also found to be positive, and hæmolysis starts only after a critical quantity of lysin has been bound to the cells. This corresponds to an adsorption of $0.45 \times 10^{8}$ molecules of diacetyl deoxycholic acid per cell for 50 per cent hæmolysis. A figure of $1.0 \times 10^{8}$ molecules per cell was found for both alkyl sulphates[2].

Table 1

| Quantities of diacetyldeoxycholate In initial solution (γ/ml.) | Bound to the cells (γ) | Hæmolytic rate (per cent) |
|---|---|---|
| 4·800 | 250 | 88 |
| 4·000 | 242 | 38 |
| 3·200 | 234 | 6 |
| 2·400 | 210 | 4 |
| 1·600 | 212 | 3 |

Table 2

| Time (min) | Hæmolytic rate (per cent) | Diacetyldeoxycholate bound to the cells |
|---|---|---|
| 0 | 3 | 352 |
| 5 | 10 | 364 |
| 30 | 15 | 408 |
| 60 | 20 | 479 |
| 225 | 25 | 528 |
| 390 | 50 | 520 |

In the case of the alkyl sulphates, it was not possible to follow the adsorption-rate with time as the adsorption speed was too high; but in the case of deoxycholate it was possible to relate the time function of adsorption and hæmolytic rate using the same technique (Table 2).

We find evidence here of further development of hæmolysis after an initial rapid adsorption of the main quantity of the diacetyldeoxycholate.

The failure of Ponder to find adsorption of sodium taurocholate in a hæmolytic system can be explained by the recent results of Pethica and Schulman[4]. They found practically no hæmolytic activity for the highly purified compound and the activity was attributed to the accompanying impurities. A constant concentration of the taurocholate before and after the hæmolysis can thus be expected.

## Swarming of *Nereis succinea* (Leuckart) off the East Coast of Canada

In June 1952 the crew of a fisheries patrol boat cruising in Miramichi Bay, New Brunswick, observed what they took for a sand-bar in an unexpected situation. On closer inspection they found that there was no such bar, but that the surface of the sea over a wide area was in a state of violent turmoil ("a sort of boiling") due to the presence of enormous numbers of polychætes. The area covered was some 150 yards in radius and was broken up into several minor patches. The largest one, from which they took a sample of the polychætes, was estimated to be 75 ft. long and 15 ft. wide, and the polychætes seemed to extend to about 2 ft. deep. The tide was low at the time and the depth of the water about 7 ft. The bottom consisted of hard mud. The observation was made on a fine, warm day.

The polychætes involved were the heteronereid forms (both sexes) of *Nereis succinea* (Leuckart). This is the first record of that species from eastern Canadian waters, though it is known from the eastern coast of the United States, usually under the name *Nereis limbata* Ehlers. Ehlers[1] described in detail the male heteronereid of *Nereis acutifolia* Ehlers, which appears to be another synonym of *Nereis succinea* (Leuckart) (cf. Monro[2]). The specimens from Miramichi Bay agree closely with Ehlers's description.

We know of no other case of the swarming of a nereid with such activity and in such concentrated masses as occurred in this instance, and should be glad to hear of any that has been recorded.

The specimens were submitted by the collectors to Mr. R. A. McKenzie, a representative of the Fisheries Research Board of Canada at Chatham, New Brunswick, and were forwarded by him to Dr. A. H. Leim, of the Atlantic Biological Station, St. Andrews, New Brunswick, who, in turn, sent them to us for identification. We are indebted to the former for particulars of the conditions of swarming.

## Factors affecting Choice and Judgment

Dr. R. G. Hopkinson[1], in his account of a meeting of Section J of the British Association at Belfast, discusses certain aspects of subjective assessments. While admitting that subjective judgments can be of very real value, it does seem that Hopkinson has under-estimated some of their disadvantages in comparing them with 'objective' methods of measurement.

When subjective and objective methods of measurement can equally well be used, it may well be that, in certain cases, smaller differences can be detected by the subjective method. The 'success' of subjective assessments, however, is generally described in terms of accepted threshold-levels (generally 80 per cent correct), and there may have to be a relatively very large difference between stimuli before they can be distinguished 100 per cent correctly. In fact, a 100 per cent discrimination may be unattainable by subjective methods.

It is above all when absolute judgments have to be made, however, that subjective methods become inefficient. This is because a subjective judgment tends to be affected by others made just previously and, in particular, to be influenced by the average quality-level of the group within which the samples to be assessed are presented. Thus, for example, food products have often to be assessed by experts in terms of mental standards, when it is not possible to keep a standard sample for comparison purposes. In such a situation, Dove[2] has shown that a sample of sweet corn is described quite differently when presented with groups of samples differing in quality, and Sheppard[3,4] has shown that absolute judgments for firmness of a given sample are affected by the average firmness of the group within which it is judged.

It is interesting that Hopkinson found little variation in glare settings, since such judgments are likely to be more important biologically to the individual than the type of assessments described above, and it may be for this reason that they are made more accurately. Since fatigue mechanisms usually operate to safeguard the individual from physiological damage, it would be interesting if they could be shown to do so with a greater degree of accuracy than is usual in psychological assessments.

There are, however, other possible reasons for these differences. Thus it may be easier to maintain a mental standard for visual judgments than it is for flavour or tactual assessments; while it seems likely that the criteria for glare ratings can be more successfully defined. A more probable explanation is that the stimulus range is (subjectively) wider for glare situations than for the others referred to and, since Hopkinson used a small number of rating values, it is for this reason that the subjective assessments appear to be reliable. The other possibility is that the difference can be attributed to the use of the 'method of adjustment' by Hopkinson, since this is not a commonly used psychophysical method.

There are two further disadvantages of absolute judgments made subjectively: the first is that the skill and knowledge required to make them have to be passed on by training, whereas an objective method of measurement can be precisely described in a written form, and can be used again after any period of time by anyone who is sufficiently skilled to construct and use the apparatus required. Secondly, fatigue may be important; thus, for example, a judge should not make more than five to seven assessments for flavour at one time. Instruments do not have this disadvantage.

With reference to Hopkinson's comments on the training of subjects to make judgments, Harper[5] has been able to show that relative discrimination, at least, can be improved by suitable training; but whether the factors influencing absolute judgments, as described above, can be overcome by suitable training, is less clear.

---

MR. SHEPPARD'S letter directs attention to one of the many matters associated with subjective judgments that failed to receive consideration at the Belfast meeting, and I hope he will accept that my summary was concerned only with problems which arose out of the meeting itself. However, I am grateful for the opportunity which his letter affords to acknowledge that there are indeed situations where subjective judgments should be replaced by objective measures. I would go so far as to assert that, wherever the relation between the subjective reaction and the physical variables is fully understood, and the physical variables can be measured with the necessary degree of absolute and repetitional accuracy, the objective method should be used. For this reason we use, for example, photoelectric methods of photometry to replace visual methods, having satisfied ourselves that we understand the exact nature of the visual response to radiation of complex spectral characteristics inasmuch as it affects the ability of the eye to judge amount of light.

The need for subjective judgments arises when the relation between the physical variables and the subjective reaction is not fully understood. Then my contention is that it is often a wiser course to rely on a carefully planned series of subjective judgments than on a physical measure the inadequacy of which is hidden by its ability to repeat its judgments with apparent consistency. An instrument can be made which gives an objective reading which it correlates well with the subjective judgment of the 'graininess' of a cathode-ray tube screen, provided the same particle-size distribution of screen material is always used. Change the distribution, or the shape of particle, and the correlation breaks down. The instrument continues to churn out its apparently consistent readings, but these are no longer correlated with the subjective judgment they purport to replace.

The decision as to whether one should replace a subjective judgment by an objective measure should be based on the nature of the physical variables which govern the subjective reaction. Where one variable only is involved (for example, the amount of light on the recognition of the presence of a signal) or where only one variable can be assumed for the purpose to be involved (for example, the air temperature or the feeling of warmth when other factors are constant), this easily measured physical variable can be taken as an objective measure of the subjective quality.

In other situations the subjective quality can be linked with certainty to the physical variables, but the relation is so complex that only in special cases does the design and maintenance of an instrument based on it justify itself. Such a special case is the measurement of light of complex spectral quality, where a 'physical eye' of considerable complexity is needed in order that the manufacturer of fluorescent lamps may control his product.

Further up the scale are situations, like the judgment of paper quality, the characteristics of semi-diffusing materials for lighting, or the quality of wine, where only partial success has been achieved in establishing the complete range of physical variables which govern the subjective judgment. Such qualities can, however, be judged with accuracy, after training and experience, provided the judging is assisted and not deceived by the experimental conditions. It is in such cases that I query whether the time and effort expended in a search for an objective measure is justified.

Further still up the scale are judgments of æsthetic quality. Some of the physical factors which influence such qualities are understood—the proportions of a building, the order of progression of musical intervals, and so on—but the quality is essentially dependent on the weighting and integration, at a high level of thought, of a greater number of physical variables than could be handled at one time by any objective assessing-equipment at present within human conception.

It is probable that the clue to any remaining differences between Mr. Sheppard and myself is tied up in what we understand by a 'reliable' subjective judgment. He asks for every single judgment to be exact. I only ask that the mean of a convenient number of judgments should not drift, and that the variance of the judgments should be small in relation to the differences in which my experiment is interested. If this difficulty could be resolved, it might be possible to agree that some of the effort now devoted to the development of objective measures of complex situations might well be expended on the systematizing of a discipline for the conduct of subjective experiments and the training of human judges. There is still a great deal of prejudice which leads to distrust of experiments involving human judgments. This can be swept away only if the tools used in subjective experiments are sound, and are used in a way which commands respect.

R. G. HOPKINSON

Building Research Station,
Watford, Herts.

# FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

## Monday, May 11

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. Koyré: "An Experiment in Measurement in the XVIIth Century" (Special University Lectures in the History and Philosophy of Science, 1).*

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. J. A. Steers: "The East Anglian Floods".

## Tuesday, May 12

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. Koyré "An Experiment in Measurement in the XVIIth Century" (Special University Lectures in the History and Philosophy of Science, 2).*

ILLUMINATING ENGINEERING SOCIETY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Annual General Meeting.

INSTITUT FRANCAIS DU ROYAUME-UNI (at 15 Queensberry Place, London, S.W.7), at 6 p.m.—Dr. P. Lépine (Paris): "Le Problème du Cancer dans ses relations avec les Virus".*

## Wednesday, May 13

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Richard Southwell, F.R.S.: "Training for Science and Technology" (Trueman Wood Lecture).

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. Y. Craig: "The Palaeoecology of the Top Hosie Shale, Kilsyth, Stirlingshire"; Dr. D Flinn: "On the Time Relations between Regional Metamorphism and Permeation in Delting, Shetland".

BEDSON CLUB (in Lecture Theatre 1, King's College, Newcastle-upon-Tyne), at 5 30 p m.—Prof. J. H. Hildebrand: 91st Bedson Lecture.

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Dr. R. Warnecke and Monsieur P. Guenard: "Recent Work in France on New Types of Valve for the Highest Radio Frequencies".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. W. H. J. Vernon: "Corrosion—a Field for Action" (Chairman's Address).

## Thursday, May 14

COUNCIL FOR THE PRESERVATION OF RURAL ENGLAND (at the Royal Institution of Chartered Surveyors, 12 Great George Street, London, S.W.1), at 2.30 p.m.—Annual General Meeting.

LABORATORY ANIMALS BUREAU (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 2.30 p m.—Symposium on "Laboratory Animals".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. H. Cary Gilson: "The Freshwater Biological Association".

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Annual General Meeting, at 8.30 p m —Dr. L. H. Gray: "The Initiation and Development of Cellular Damage by Ionizing Radiation" (Thirty-second Silvanus Thompson Memorial Lecture).

## Friday, May 15

INSTITUTE OF NAVIGATION (joint meeting with the CHALLENGER SOCIETY, at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. G. E. R. Deacon, F.R.S., and Commander G. S. Ritchie: "Navigation and Oceanography".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. A. Koyré. "Philosophical Factors in the Evolution of Science" (Special University Lectures in the History and Philosophy of Science, 3).*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Edwin Hubble: "The Observational Evidence for an Expanding Universe".

## Friday, May 15—Saturday, May 16

PHYSICAL SOCIETY (at the Imperial College of Science and Technology, Imperial Institute Road, London, S W.7).—Discussion on "Recent Research in Electron Optics".

## Saturday, May 16

ROYAL PHOTOGRAPHIC SOCIETY, SCIENTIFIC AND TECHNICAL GROUP (in the Arthur Worthington Hall, The University, Manchester), at 10 a.m.—Conference on "Photographic Science and Technique".

BIOCHEMICAL SOCIETY (in the Department of Physiology, The Medical School, Hospitals Centre, Birmingham), at 1.45 p.m.—Scientific Papers.

BRITISH PSYCHOLOGICAL SOCIETY (in the Psychology Department, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Mr Harry Kay. "Remembering—some Recent Experiments".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ESSO STUDENTSHIP IN CHEMICAL ENGINEERING—The Registrar, University College, Gower Street, London, W.C.1 (May 15).

SENIOR LECTURER (with general experience of veterinary practice, and a particular knowledge of veterinary medicine in relation to farm animals and metabolic diseases) IN VETERINARY MEDICINE—The Secretary of University Court, The University, Glasgow (May 15).

ASSISTANT, Grade B (with honours degree) IN CHEMISTRY, to teach general chemistry up to Intermediate level and assist with teaching of physical chemistry to B.Sc. special standard, at Brighton Technical College—The Director of Education, 54 Old Steine, Brighton (May 16)

SENIOR LECTURER IN ORGANIC CHEMISTRY (with good honours degree in chemistry and, if possible, appropriate teaching, industrial and research experience, in pure or applied organic chemistry)—The Principal, Acton Technical College, High Street, Acton, London, W.3 (May 16).

SENIOR SCIENTIFIC OFFICER (university degree essential; experience in field experimentation and statistical analysis of results highly desirable), and an EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICER (must have at least N.D.A. or similar qualification, and practical experience with farm machinery essential)—The Secretary, Scottish Machinery Testing Station, Howden, Mid Calder, Midlothian (May 18).

READER IN PATHOLOGY at Westminster Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 19).

SUPERINTENDENT (Deputy Chief Scientific Officer) OF THE AERODYNAMICS DIVISION, National Physical Laboratory—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4201/53 (May 21).

ASSISTANT PHYSICISTS (Senior and Basic grades)—The Secretary, Sheffield Regional Hospital Board, Broom Cross, Tree Root Walk, Sheffield 10 (May 23).

BIOLOGICAL RESEARCH ASSISTANTS (2) at the Biological Research Institute, Grange-over-Sands (one to take entire responsibility for care and maintenance of the research laboratories, the other for survey and experimental work on soil fauna in the field and laboratory)—The Establishment Officer (A), Nature Conservancy, 91 Victoria Street, London, S.W.1 (May 26).

SCIENTISTS (physicists, physical chemists or electrical engineers with at least second-class honours degrees or equivalent, and interested in the physics and chemistry of surfaces) to undertake investigations on both laboratory and pilot plant scales into novel methods of separating coal from associated minerals (Ref. TT/624); a SCIENTIST, Grade II (Ref. TT/625); a SCIENTIST, Grade III (Ref. TT/626); and a SCIENTIFIC TECHNICAL OFFICER, Grade I (Ref. TT/627) to lead a small team engaged in the systematic measurement of the physical properties of coal and associated minerals, in the Physics Department—The National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, Glos, quoting the appropriate Ref. No. (May 26).

AGRICULTURAL ECONOMISTS (2) and ASSISTANT AGRICULTURAL ECONOMISTS (2) in the Provincial Agricultural Economics Service—The Registrar, The University, Reading (May 30).

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF GEOLOGY—The Registrar, The University, Liverpool (May 30).

LECTURER or ASSISTANT LECTURER IN PHYSICS (with good honours degree in physics)—The Dean, Medical School Office, Guy's Hospital, London, S.E.1 (May 30)

LECTURER IN EXPERIMENTAL PHYSICS—The Registrar, The University, Liverpool (May 30).

RESEARCH ASSISTANT (with at least two to three years experience in postgraduate research work) IN THE DEPARTMENT OF ORGANIC CHEMISTRY—The Registrar, The University, Liverpool (May 31)

RESEARCH BOTANIST (with good honours degree) for research on biennial bearing in fruit trees and other pomological problems—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (June 1).

SENIOR and JUNIOR FELLOWSHIPS—The Chief Superintendent, Telecommunications Research Establishment, Malvern, Worcs (June 1).

LECTURER and ASSISTANT LECTURERS (3) IN THE DEPARTMENT OF BIOCHEMISTRY (one appointment will entail research in certain physical aspects of biochemistry)—The Secretary, University College, Gower Street, London, W.C.1 (June 8).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF OCEANOGRAPHY—The Registrar, The University, Liverpool (June 13).

CHEMIST (Experimental Officer grade) (with pass degree or equivalent qualifications and substantial experience in routine chemical analysis) for mineral analysis of plants—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (June 15).

SENIOR LECTURER IN VETERINARY MEDICINE AND ANIMAL HEALTH, a LECTURER IN GRASSLAND ECOLOGY, a LECTURER IN AGRICULTURAL CHEMISTRY, and a LECTURER IN SOIL SCIENCE, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 27).

RESEARCH BOTANIST (with good honours degree and substantial postgraduate experience, preferably in perennial crops) IN THE POMOLOGY SECTION—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (August 31).

ASSISTANT PHYSICIST (with honours degree in physics) IN THE RADIOTHERAPY CENTRE—The Physician Superintendent, St. Luke's Hospital, Guildford.

ASSISTANT PROFESSOR OF PHYSICS (with a well-developed knowledge of geophysics, and established interest in fundamental geophysical research)—Prof. W. H. Watson, Department of Physics, University of Toronto, Toronto 5, Canada.

CHEMIST in the Public Works Department, Gold Coast, for the supervision of the purification of Government water supplies and investigation of new supplies—The Commissioners for the Gold Coast, Melbourne House, Aldwych, London, W C.2.

Junior Assistant Chemist (with university degree including chemistry)—The Director, Fruit and Vegetable Canning and Quick Freezing Research Association, Chipping Campden, Glos.

Metallurgists and Metallurgical Engineers for (*a*) research on mild steel weld metal involving a relatively new problem of considerable interest and importance; (*b*) research on mild steel weld metal involving a constitutional approach to cracking problems; (*c*) research on the welding of high strength aluminium alloys—The Secretary, British Welding Research Association, 29 Park Crescent, London, W.1.

Research Fellow in Histochemistry—The House Governor and Secretary, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

Senior Research Assistant (with good honours degree in engineering, practical experience and/or research training) in the Department of Civil and Mechanical Engineering—The Registrar, The University, Nottingham.

Senior Scientific Officers at Sellafield, Salwick and Culcheth, to lead research teams in theoretical and experimental work on the following: general physics and applied nuclear physics concerned with operation of nuclear reactors and associated processes, including health physics; physical and inorganic chemistry of metals and compounds used in atomic energy processes, including radioactive materials; extraction, purification and recovery of metals; refractory materials; physical metallurgy of radioactive metals; melting and casting of metals; X-ray crystallography of unusual metals and compounds—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, quoting 444.

# THE NUFFIELD FOUNDATION

THE Nuffield Foundation was established by Lord Nuffield in April 1943 with wide objectives, including the advancement of health and the prevention and relief of sickness, particularly by medical research and teaching and the organization and development of medical and health services; the advancement of social well-being, particularly by scientific research, and the organization, development and improvement of technical and commercial education; the care and comfort of the aged poor; and the advancement of education. These four objectives are sufficiently wide in themselves, but any other charitable purposes may be included in the Foundation's objectives on the written declaration of either Lord Nuffield in his lifetime or, after his death, of the trustees. That provision should sufficiently eliminate the danger of the dead hand, which Lord Nathan's Committee has been investigating since 1950; nor have successive annual reports of the Foundation indicated that there is any danger of the Foundation spreading its resources too thinly over too many objectives.

The principles upon which the Foundation has based the policies which have guided the administration of grants exceeding, in the past ten years, four million pounds, have been clearly indicated from time to time in its annual reports, notably in the fourth and sixth reports, in 1949 and 1951, respectively. Already when Lord Beveridge in 1948 published his report on "Voluntary Action", the work of the Foundation could be cited as an outstanding example of the way in which such independent private ventures could contribute to scientific and social advance, even with greatly increased State support for learning and research. The contribution which voluntary action could make to learning and culture by fostering enterprise and initiative, and ensuring that room for experiment and for testing opinion was maintained, had been fully demonstrated in the work of its first five years.

The tenth birthday of the Foundation was marked by a reception on April 30 at its new headquarters, Nuffield Lodge, Regent's Park, London, N.W., at which Queen Elizabeth the Queen Mother named a room "The Founder's Room" and unveiled a plaque in honour of Lord Nuffield. The first part has also been published of a review of the Foundation's first ten years, in which the main policies pursued are briefly recorded and the kinds of work supported are generally indicated. The grants themselves and, where appropriate, the progress made, are to be described in more detail in a second part, with appendixes, listing published research which the recipients of grants wish to attribute to the Foundation's help, and the names of Foundation fellows, scholars and bursars appointed during the decade. No attempt is made in this first part to distinguish the programmes of the first two five-year periods, though they have differed somewhat in emphasis; nor are the policies of the Foundation here discussed in relation to the current trends of government policy in quite the same way as they have been, for example, in the third, fourth or sixth annual reports.

Nevertheless, the record is of both public and scientific interest at a time when the place and activities of independent organizations in the promotion of research are being widely discussed both in Great Britain and in the United States of America. As a private fund serving the community, the Foundation has sought to be of service, in part directly, by forwarding projects of possible public benefit; and, in part indirectly, by providing a stimulus to research workers, some of whom might abandon promising but speculative work if there were not known to be resources available to support just this kind of pioneering. Reviewing, for example, the Foundation's support of the physical sciences and its early concern to assist in re-establishing university research in fundamental physics after the War, the review points out that university departments were endangered by the very successes of science and scientists in war-time work.

While most of the fundamental ideas and advances, so rapidly exploited to contribute to victory, had been born in academic departments before the War, there was a tendency to forget or neglect these origins and to attribute the ideas to the environment in which they had only been brought to swift and fruitful maturity. The urgent factor was the danger that the official establishments of government-sponsored applied research might prove too tempting to the brilliant men they had recruited from academic research, and some would be deterred by the prospect of inadequate apparatus and technical assistance from returning to the essential work of advancing knowledge and training research workers.

While not all the fears about the long-term after-effects of war on the standard of academic research proved to be justified, the part which the Foundation was able to play here was significant, and was the more valuable in that it was given quickly at a critical time. The lesson of research conducted under the press of war, that it is possible and worth while to multiply the effective work of a few good men by giving them technical tools and technicians on a scale well beyond that of peace-time, was applied by a private institution with a swiftness and efficacy that no government-controlled establishment could hope to emulate. As the review rightly but modestly remarks, when foundations and trusts accept such proper challenges to pioneer in the public interest, they should be judged not only by the success of this or that particular venture, but also by their general record of adventurousness.

The work here reviewed is in reality the product of less than ten years: the Foundation's first five-year programme dates from 1944. In the medical field, emphasis was laid on normal health rather than specific diseases, especially on child health, industrial health, and dental health, apart from rheumatism, the early study of which brought Capt. Oliver Bird's benefaction of £450,000; and, in physics, on nuclear research. For the second period, to end in 1954, the Foundation expressed a preference for assisting biological and sociological studies, and a willingness to begin to consider grants for research overseas; but a further desire to bring scientists and others together in research on practical problems has met with few opportunities. Grants for the welfare of old people and for research into their needs have continued through both periods, totalling £925,000, since 1947 chiefly through the National Corporation for the Care of Old People. The policy of awarding fellowships and similar personal help for training and travel has also continued over the whole period, accounting for a further £831,000, though the schemes have been varied from time to time to serve different purposes or opportunities. Grants for medical work totalled £786,000, including £229,000 for rheumatism; £347,000 for biological research; £560,000 for research in physics; £463,000 for projects in the social sciences; while research specifically related to agriculture received £32,000.

Such figures attest the scale and range of the Foundation's activities, rather than its pioneering character. That, however, is amply revealed in the sections which review in fuller detail the Foundation's policy in particular fields. In the medical sciences, for example, in accordance with a general policy of establishing and encouraging the study of child health, industrial health and dental health as academic subjects pursued at the highest level of academic work, and linked, where appropriate, to the conditions of the surrounding community, it has granted £100,000 towards the establishment in the University of London of a worthy institute of child health, and has assisted in making the study of health as it is affected by work and working conditions a subject of research in the Universities of Durham, Glasgow and Manchester. In rheumatism, besides encouraging fundamental work into causes and scientifically controlled trials of existing therapy, the Foundation has since 1949 supported much chemical work on the total synthesis of cortisone and the production of analogous substances with similar but less harmful effects.

In the biological sciences, where grants have on the whole been numerous and small, rather than, as in physics, few and large, the pioneer character of the programme is specially pronounced, the aim being to encourage work on the normal mechanisms of growth, differentiation and self-maintenance of living things. The early emphasis on nuclear research in physics has already been noted: besides this, the Foundation has sought to foster work on promising new techniques and tools of physics of value not only there but also in the investigation of biological problems by physical methods. In agriculture the Foundation has supported physical projects like that at the University of Cambridge concerned with soil mechanics as it affects drainage and tillage; but under its auspices also a study-group of economists, agricultural scientists and practical farmers is attempting to deduce in essentially a scientific way the long-term principles which should underlie any shorter-term policy for British agriculture. In the social sciences, where the choice of men, projects and institutions for support has, of necessity, been opportunistic, the absence of any clear pattern reflects not only the paucity of promising opportunities, especially for fundamental or adventurous research, but also the lack of coherence and systematic study in these subjects. Moreover, the review points out that the research which can be encouraged by the grants of private bodies is necessarily limited, and steady progress is unlikely until more public money is devoted to research as well as to teaching, so that the subject can be developed systematically and scientifically by an assured body of workers permanently established in universities.

This part of the review demonstrates clearly the primary function of the independent institution as providing the growing points of new knowledge, or new projects. The work on the care of old people, the basis of which in scientific research, especially fundamental research, is made clear, does, it is true, illustrate the same point; but it does not emphasize the related point that the independent institution should not be expected to commit its resources permanently to the support of activities the value of which, whether to society or scholarship, has been well attested. The value of the voluntary body or private institution lies precisely in its freedom to transfer its resources freely, to test the value of activities, projects and lines of investigation for which it would be premature or difficult to secure official or government support. Once the value of that line of investigation has been established, the voluntary body should seek to withdraw, leaving support increasingly to official sources, and to use its own resources at some fresh point on the frontiers of knowledge.

The dilemma which the Foundation and other such institutions are increasingly likely to face does not appear as clearly in this review as it did in its annual report two years ago, and also in that of the Carnegie United Kingdom Trust. The dilemma lies in choosing between helping, for example, academic activities during a time of public economy, and encouraging novel proposals which find it even more difficult to command a hearing. Yet the review, like Dr. Raymond Fosdick's recent review of the first forty years work of the Rockefeller Foundation, leaves us in no doubt where the primary responsibility of the independent institution lies.

It is encouraging to find that the principles and policies on which these two Foundations have been administered have so much in common. The Nuffield Foundation has less to say than Dr. Fosdick about those principles, but its policies are manifestly inspired by the same ideas of pioneering responsibility and willingness to risk capital adventurously on projects that the State will not or cannot support; and by the belief that promising men and creative ideas are the first essential. Judged by the ideas and practices set forth by Dr. Fosdick and also by Lord Beveridge, the Nuffield Foundation has acquitted itself well. The admirable record here so modestly told should stir more than the scientist to fresh thought as to the ways and means by which in the society of to-day the freedom of such bodies to continue their activities can best be ensured and the fullest use made of their services.

# TREATISES ON PHYSICAL CHEMISTRY

## An Advanced Treatise on Physical Chemistry

By Prof. J. R. Partington. Vol. 3: The Properties of Solids. Pp. ix+639. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1952.) 70*s.* net.

## A Treatise on Physical Chemistry

Edited by Prof. Hugh S. Taylor and Samuel Glasstone. Third edition, in 5 Vols. Vol. 2: States of Matter. Pp. v+701. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1951.) 75*s.* net.

THE general characteristics of Prof. J. R. Partington's "Advanced Treatise on Physical Chemistry" were well established by the first two volumes, and there is little new which a reviewer can say about the third. It maintains all the virtues of the earlier two: scrupulous care over detail and historical attribution, a clear and critical account of experimental methods, and a wealth of references (15,511 in the present volume) and numerical tables. These qualities appear all the more remarkable when one considers the sheer mass of material to which they have been applied in the three volumes of the treatise, and it becomes increasingly clear that staying-power is not the least of the author's qualifications for his task.

Those readers who disliked certain features of the earlier volumes will probably react in the same way to parts of the present one. For example, I am still unconvinced of the value of reproducing so many empirical equations: they are admittedly of no theoretical significance, and it may be doubted whether their inclusion is of much practical assistance, since it is impossible in the space available to give a critical account of their scope and accuracy. Similarly, some may feel that scant space is given to certain recent theories which are still in a fluid state—for example, the basis of hysteresis phenomena, or the mechanism of crystal growth. However, both these criticisms apply with less weight to the present volume than to the preceding one on liquids. This is not because of any change in Prof. Partington's approach, but because we understand the behaviour of solids much better than that of liquids. The need for empirical relations is therefore less: similarly, much more of the theory has stood the test of time and experiment, and thus escapes the somewhat severe censorship which the author applies to speculative and incomplete theories.

A number of particular points may be mentioned. The chapter on isomorphism is probably unique, and, although much of it is of purely historical value, it makes interesting reading. On the other hand, the whole subject of atomic and ionic radii in crystals is given a most inadequate treatment in four pages at the end of this chapter. The section on the elastic properties of solids gives an admirably clear exposition of a subject which often offers difficulties to physical chemists with a chemical upbringing. An excellent account is given of the thermal properties of solids, and the comparison of theory and experiment is critical and well-balanced. The whole book abounds with items of recondite information such as we expect from Prof. Partington, many of them presented with a certain dry humour. Thus, it is intriguing to be referred (p. vii) to a work entitled "Gelehrtenmentalitätsbesonderheiten psychologisch-pathologisch betrachtet" (though tantalizing to be told that it is now unobtainable), and it would be interesting to know whether there is any foundation for the author's surmise (p. 266) that American writers are reluctant to use the name "specific heat" because it has for them a double meaning unknown to the rest of the world.

The first volume of the treatise edited by Prof. H. S. Taylor and S. Glasstone appeared in 1942, and the Second World War has delayed until now the publication of the second. If we accept the dictionary definition of 'treatise' as "a literary composition dealing systematically with a definite subject", then it is doubtful whether the present compilation can claim this title. The second volume contains five uncorrelated articles by different authors, each on a particular topic connected with states of aggregation, and there are naturally wide differences in the method of treatment. In this notice each will be discussed separately in turn.

"The Kinetic Theory of Ideal Gases" (187 pp.), by K. F. Herzfeld and H. M. Smallwood, builds up the subject progressively from the simplest foundations, great care being taken to explain the physical meaning of the expressions derived. The extension of the theory to imperfect gases is frequently indicated, and ultimately complex problems such as thermal diffusion and radiometer phenomena are dealt with. The exposition is throughout excellent, and there are many useful formulæ and tables of data. There is little direct account of experimental work, but numerous examples are given of the application of kinetic theory to practical problems.

In "The Thermodynamics and Statistical Mechanics of Real Gases" (166 pp.), by J. A. Beattie and W. H. Stockmayer, no account is given of experimental work, though some of the tables give data derived from experiment. The first two-thirds of the article consists mainly of a very thorough compilation of thermodynamic formulæ for single gases and gas mixtures in terms of the first four virial coefficients. It will certainly be useful to specialists wishing to tackle particular problems involving imperfect gases (though much of it has already appeared in an article in *Chemical Reviews*), but will be of little interest to anyone else. The remainder of the article, dealing with intermolecular forces, has more general appeal. A clear account is given of the theoretical interpretation of these forces, and of the way in which information about them can be obtained from observed equations of state. On the whole, this section is considerably more advanced and specialized than the remainder of the volume.

"The Liquid State" (68 pp.), by G. E. Kimball, has a misleading title, since, in fact, it contains only a description of some of the current statistical treatments of pure liquids. The theoretical exposition is clear; but there is little reference to experiment, and the reader might well end up with no conception of the real achievements or deficiencies of the theories described.

A successful treatment of a limited field is given in "X-Ray Analysis of the Solid State" (88 pp.), by J. G. White. The descriptions of the theory and practice of X-ray analysis are well designed for reading by the non-specialist, and are followed by a large number of examples ranging from simple ionic crystals to sterols and polymers. At times one sees (as in other articles) the disadvantage of a treatise consisting of separate articles on specialist topics: thus the short section on hydrogen bonding suffers in interest and in accuracy because no reference is made to the information obtainable from electron diffraction, spectra, or thermodynamic properties. In the main, however, this section gives a well-balanced and lucid account of the subject.

The final section, "The Colloidal State and Surface Chemistry" (183 pp.), by E. O. Kraemer, J. W. Williams and R. A. Alberty, covers a wider field than any of the other articles in this volume. Colloidal systems are not relegated to a mysterious domain obeying rules of its own, but are related to ordinary solutions, on one hand, and to macroscopic surfaces, on the other. The material is well chosen, with a judicious blend of theory and experiment, and although adequate attention is given to modern theories and physical methods of investigating colloids and surfaces, the classical experimental background is not neglected. The exposition is good, and this section should be valuable to students of chemistry in general.

Now that the compilation by Taylor and Glasstone has again got under weigh, we have in progress two major works on physical chemistry of comparable size, and it is of interest to attempt a general comparison of the two publications to date. Partington's treatise is characterized by its thoroughness and uniformity of treatment, and by the particular attention given to the experimental and historical aspects of the subject. Any scientific worker who wishes to obtain a complete and unbiased knowledge of what has been done in a particular field of physical chemistry will be well advised to consult Partington. (He may find relatively little about current theoretical views; but he will certainly find references to these.) On the other hand, the average student needs his information pre-selected (if not also pre-digested) to a greater degree, and he would be overwhelmed by the wealth of learning to be found here. Because of its multiple authorship, Taylor and Glasstone is much more uneven in its nature and quality, and must inevitably contain overlaps and omissions. Its general aim appears to be to present the current position of physico-chemical theory, rather than to describe the experimental or historical foundations of the subject. Some sections (for example, the last two in the volume under review) are well suited for reading by students, but others are too specialized and advanced for this purpose. The latter will be useful to research workers who wish to extend some branch of physical chemistry along its present lines of development, but they must turn to Partington if they seek the unorthodox view or forgotten observation which might transform the subject.

Both books should be in any well-equipped chemical library.

R. P. Bell

## PRESTRESSED CONCRETE

### Prestressed Concrete

By Prof. Kurt Billig. Pp. x+470. (London: Macmillan and Co., Ltd., 1952.) 36s. net.

Engineers first had to build with materials as provided by Nature such as timber, stone and earth. The coming of the industrial age has seen the application of man-made materials such as steel and concrete and their combination in reinforced concrete. For the past fifty years engineers have been building composite structures in which the weakness of concrete in tension is made good by the addition of steel reinforcement. The two materials are not ideally suited for working in harmony, for the low ductility of concrete limits the allowable steel stress to a fraction of that possible with high-strength steels.

The ingenuity of man, therefore, conceived the idea of self-straining the materials by putting the concrete under an initial compression in equilibrium with an initial tension in the reinforcement. This corresponds to a change in the origin of the concrete stress/strain curve, and the concrete can take differential stresses due to applied loading by reductions in the applied initial strain before getting into the danger zone of cracking due to tensile strains. It corresponds on an engineering scale to what the metallurgist does on a molecular scale when he cold-works metals. A new industry, that of prestressed concrete, has therefore come into being and is rapidly approaching maturity. Its adolescence is here chronicled in this book by Prof. Kurt Billig. The author is well qualified for such a task, for he has devoted many years to the subject and observed its growth in many countries.

The first part of the book is an almost encyclopædic account of the development to date. The pioneers did not foresee the loss in prestress due to shrinkage and creep of the concrete and creep of the steel. It was not until Freyssinet in 1928 obtained a solution by the combined application of high-tensile steel and high-grade concrete, with initial stresses so great that after all losses the effective prestresses were still adequate, that real success was obtained. Prof. Billig gives a full and well-documented account of the early attempts, the subsequent success, and even of developments that have not yet been brought to a commercial stage. As development proceeds, subsequent books will have to exercise a more selective method; but here we have a very useful source book for the future, although the material is not such as one would, in Great Britain, expect to find in what is described as a text-book. There is much to convince the engineer, interested in saving steel, that this new medium will have a definite place in the economy of the future.

It is noteworthy that the greatest development has taken place in countries which have to make sixpence do the work of a shilling, and that extra design costs are faced in order to make material savings. Britain has played its part in this development, but the United States have been able to adopt a somewhat more lavish attitude to materials and, despite their greater number of available technologists, are still relatively behindhand in the matter of prestressed construction.

The second and third parts of the book are more of the character of a text-book. Part 2 consists of a review of the general principles of design, and Part 3 deals with actual design problems, full numerical examples being given. Owing to the number of stages of loading to be considered in design, the book (and the subject) suffers from a multiplicity of symbols which does not make for easy reading. It is to be hoped that the Gothic symbols will not be perpetuated.

Data that have obviously cost Prof. Billig much effort—for example, tables of properties of sections—are put at the service of other designers. The book has much in it for those prepared to work hard, and, if necessary, to use their imagination; a chapter on the design of a radio tower does not include a single illustration to help the lazy. The publishers are to be congratulated on the quality of their work.

## THE CIVIL SERVICE IN BRITAIN

### How the Civil Service Works

By Bosworth Monck. Pp. vi+258. (London: Phoenix House, Ltd., 1952.) 25s. net.

To a large extent the steadily growing number of books on the Civil Service in the ten years or so since the publication of H. E. Dale's "The Higher Civil Service" and E. W. Cohen's "The Growth of the British Civil Service" have been concerned with the reform of the Civil Service and its adaptation to the problems of a society in which the Civil servant is required to take much more positive action than even a generation or so ago. Moreover, the range of the Civil servant's activities has widened immensely and in widening has made it much more important that there should be a far clearer general public understanding of what the Civil Service is, how it works and how the range and character of its activities depend upon the duties placed upon it by Parliament and, therefore, ultimately by the ordinary elector.

To a limited extent this task was attempted by T. A. Critchley; but he too was more concerned with the appropriateness of the Civil Service to the needs of to-day, and while much of his book is factual and descriptive, it is scarcely likely to appeal to, or be read by, the ordinary citizen who most needs to be enlightened as to the character of the Service and the way he conditions its activities. For some, Sir Edward Bridges's Rede Lecture two years ago might suffice, or again, Sir Frank Tribe's articles describing typical days in the life of a Civil servant. None of these is really addressed to the ordinary citizen, and the task of interpreting the Civil Service to him has not yet been accomplished. It is assayed once again by Mr. Bosworth Monck in the present work, but for all its merits—and they are considerable—the book can scarcely achieve this all-important objective.

Mr. Monck's main purpose is to provide an account of some of the methods by which Great Britain is governed, and the particular responsibilities of the major departments of the State. He is aware of the desirability of encouraging a clearer understanding between the taxpayer and the Civil servant whose work to-day touches so intimately so many sides of the taxpayer's life, but he seems a little too preoccupied with the Civil Service he is describing and to give insufficient consideration to the reader or class of readers for whom he is writing. The result is a book which covers too much ground and is unlikely to grip the reader whom it is most desired to attract.

The book is in five parts. First, it describes the general structure of the Civil Service and the character of those who work in it. An account of the way in which the estimates are prepared, the money voted and control exercised over expenditure follows. Next comes a survey of the whole process of government in which the Civil Service is set in its appropriate perspective with regard to the Government, to Parliament and to the ordinary citizen. The relations between the public service and the government of the day are discussed in a fourth section, before in the fifth and final section of the book Mr. Monck describes in some detail the activities and responsibilities of most of the major departments. Some omissions in this section, which occupies almost half the book, are obvious to the man of science. Nevertheless, it is admirably written and, while purely factual and descriptive, is informal, though it makes no attempt at giving such snapshots of a few

Civil servants at their daily work as Mr. Critchley did. The size and complexity of the Service have in no way hindered a clear exposition of the purposes and functions of the departments, but what has gone before has diverted Mr. Monck from the popular exposition that is our primary need to-day and the first justification for a new book on the Civil Service.

It is perhaps too much to expect one who was chairman of a group which five years ago produced for the Fabian Society a report on the reform of the higher Civil Service to refrain from discussing proposals for reform, but popular exposition and serious discussion of reform are ill consorts. Nevertheless, the book would have been more likely to achieve its declared purpose had the author practised such self-denial and eschewed the suggestions for reform which are made especially in his introduction but which are scattered through the first four parts. His sensible suggestions deserve more space than could be given, but Mr. Monck also brings in some questions like that of public ownership which are less relevant to the exposition of the nature of the Civil Service and how it works. The task of popular exposition must therefore be judged as an undertaking still to be accomplished. R. Brightman

## THE TREES OF UGANDA

**The Indigenous Trees of the Uganda Protectorate**
By Dr. William J. Eggeling. Revised and enlarged by Ivan R. Dale. (Published by authority of the Government of the Uganda Protectorate.) Pp. xxx+491+76 plates. (Entebbe: Government Printer; London: Crown Agents for the Colonies, 1952.) 42*s*. net.

The first edition of this work, published in 1940, was designed to be of service both to the botanist and the layman. Mr. Ivan R. Dale, who has prepared the revised and enlarged second edition, states that he has striven wherever possible to ease the difficulties of the layman, especially of field workers in government departments and sawmills. The book is very much more attractively produced than the first edition and is a credit to both printer and publisher. It is enhanced by the addition of coloured plates by 'Joy' (Mrs. Adamson), of twenty-one line-drawings previously published by the Imperial Forestry Institute, and of some more excellent photographs by Dr. W. J. Eggeling.

The appearance of this second edition is evidence of the very real need that exists in tropical countries for simple handbooks which will enable the field worker, without a specialized knowledge of taxonomy, to identify the trees he is likely to meet within his country. A handbook such as this can be made much simpler than a Flora by dealing only with the trees of one particular territory. Some authors have tried to simplify similar books by describing only the trees they regard as the commonest. This is most unsatisfactory, as the field worker is frequently thwarted or misled when the tree he is trying to identify is not in the handbook. Dr. Eggeling has, however, wisely used the term 'tree' in a wide sense and deals with all the trees recorded from Uganda, including those which appear to be rare or which are still unnamed. Rather more than seven hundred species are described; this figure conveys some idea of the immense botanical problem which confronts the forester in tropical countries.

The descriptions of the species on the whole are very good and include characters of bark and 'slash'. Such characters are of great value in tropical rain-forest where the leafy shoots and flowers of the timber trees are usually a hundred feet or more above one's head. At this time, when Floras are being prepared for tropical East Africa, for the Belgian Congo and for Angola, and the Flora of West Tropical Africa is being revised, many botanists, as well as field workers, will find these field descriptions most useful.

There is great scope in a work such as this for really vivid and practical keys. It is therefore disappointing to find that so much of the material has been borrowed, sometimes uncritically, from other works. For example, in the key to the genera of Moraceæ, the umbrella tree (*Musanga*), which has large digitately lobed leaves unique among Uganda Moraceæ, can only be keyed out by the following characters: "stamens erect in bud", "ovule erect from the base of the ovary-cell", and "male flower with 1 stamen". Forest officers are among the first to complain when such characters are used in Floras, and it is remarkable that they should be used unnecessarily in a book which has been written, used and revised by the forest officers themselves. As another example of the unsatisfactory borrowed keys one may cite *Capparis*, which is keyed out correctly as having the sepals in two series, but the only species in the book has the sepals in a single series and should, in fact, be transferred to another genus.

The descriptions of the families which have been added by Mr. Dale are sometimes useful, but too often will, one feels, confuse the field worker who is interested only in Uganda trees; if he has a wider interest there are other works to turn to. The fruit of the Apocynaceæ is, for example, described as "usually a pair of large follicles, but occasionally a berry"; then follows the description of fifteen species, twelve of which have berries (sometimes incorrectly referred to as "drupes" in this book). In the Violaceæ, a description of the only arborescent genus in Uganda—*Rinorea*—would have been more helpful than a description of the family.

Several corrections in nomenclature and taxonomy which have been made recently by botanists have been adopted in the new edition; but others have been overlooked. Some valuable original work has been contributed by H. C. Dawkins and G. Leggat, of the Uganda Forest Department, and by Dr. G. Cufodontis.

In this book the information which is derived from the author's and revisers' personal acquaintance with the trees they describe is of real value; but the material obtained from other sources is too often inapplicable to Uganda trees, and the book is consequently marred by a number of avoidable mistakes.

One cannot help feeling that the nomenclature, taxonomy and, above all, the keys of this edition would have been greatly improved if the reviser could have undertaken his work in one of the large British herbaria. It is time Colonial Governments realized that their botanists could serve them far more efficiently if they were allowed to spend at least one-third of their working-time at Kew or the British Museum, in the herbaria and libraries of which the British Commonwealth possesses a unique and incredibly rich heritage. As it is, the Colonial botanist must make the unsatisfactory choice between hurried visits and sacrificing a large portion of his leave. R. W. J. Keay

# THE FLOOR OF THE ATLANTIC OCEAN

A DISCUSSION on "Floor of the Atlantic Ocean" was held by the Royal Society on February 26, at which the session during the morning was concerned with sedimentation, and during the afternoon with the deeper structure below the layers which can be sampled. The principal contributions during the morning were made by Dr. E. C. Bullard, Prof. P. H. Kuenen, Dr. J. D. H. Wiseman, Mr. B. C. Browne, Prof. F. P. Shepard, Prof. W. B. R. King and Dr. G. M. Lees. In the afternoon the discussion was opened by Prof. M. Ewing, and he was followed by Prof. J. P. Rothé, Dr. M. N. Hill, Dr. J. L. Worzel, Prof. H. H. Hess, Dr. T. F. Gaskell and Dr. G. P. Woollard. Those in the chair were, in order, Sir Cyril Hinshelwood, Prof. W. B. R. King, Dr. E. C. Bullard, Dr. R. Stoneley and Dr. E. D. Adrian.

In his introductory remarks, Dr. Bullard emphasized the importance of determining the methods of sedimentation in the deep sea; whether slow deposition over the whole area of the oceans, or whether cataclysmal slumping is the more important feature. He also stressed that, from the point of view of determining the climatological history of the earth from the study of the layering within a deep-sea core, it is essential to know whether in any sample the depositional sequence was exact.

Prof. P. H. Kuenen outlined the improvements in finding the characteristics of the surface layers of the deep oceans. He directed attention, in particular, to the great advances in coring methods, as shown by the largest core in the *Snellius* expedition of 1931 being only 2 m. in length in comparison with the 20 m. obtained by Kullenberg by means of his piston corer in the *Albatross* expedition, and longer cores than these are now being obtained. Further valuable contributions to the study of sedimentation from work at sea comes from the bottom photography which has been undertaken by Prof. M. Ewing and from the improvements in deep-sea echo-sounding. The latter can locate such buried surfaces as, for example, have been found by the Shell Oil Co. in shallow water at depths of 0–40 m. below the bottom. Prof. Kuenen directed attention to the necessity for international co-operation in the work of exploration of the bed of the deep sea on account of the high cost, and welcomed the existence of the International Joint Commission on Oceanography which has been formed under the auspices of the International Council of Scientific Unions. The Commission is organizing a new journal of research on the deep-sea floor (to be published by the Pergamon Press, Ltd.), and Mr. C. D. Ovey, the secretary of the Commission, is one of the editors.

With reference to the theoretical aspect of sedimentation, Prof. Kuenen directed attention to the large discrepancy which has arisen between the estimates by Twenhofel and others of the total sediment thickness and the measured values obtained by seismic methods. These indicate that, instead of an overall oceanic sediment thickness of 2–3 km., as was previously supposed, there is, in fact, much less. As a particular example, there is the ½ km. of sediments measured by Raitt in the Pacific. Low values such as these are difficult to reconcile with the accepted values of the sedimentation-rate and the estimated age of the oceans.

Prof. Kuenen next discussed the transport of sediments in the deep sea by turbidity currents. These currents—at one time known as density currents—have not been observed in the oceans, but have been observed in the laboratory and in lakes. It is believed that they can be of sufficient velocity to transport the deep-sea sands, and are characterized by the graded bedding they produce and by the interstratification of deep-sea and shallow-water sediments in such regions as the mouths of submarine canyons. The distinction between turbidity currents and slumping or sliding lies in the ability of an individual particle to move freely in the former, whereas in the latter the material moves in bulk. Turbidity currents are sufficiently mobile for their momentum to carry them far beyond the slope, but slumps, on the other hand, stop at the point where the slope becomes small. Evidence for the existence of turbidity currents is not confined to the oceans but can be found in some continental rocks. For example, the graded bedding, and the interstratification of lutite in the ripple- and flow-marked graywackes of the Ventura Basin in California and elsewhere, can be attributed to this mechanism.

The turbidity currents can be of vast size and can extend to the middle of the ocean basins, but Prof. Kuenen found it difficult to believe that the cable-breaks on the continental slope and in the deep water off the Grand Banks following an earthquake in 1929 could have been caused by them. Ewing and Heezen collated the times at which the breaks occurred and concluded that, on the upper parts of the slope, velocities of the turbidity current had reached 55 knots. Later in the discussion other speakers showed doubts of this explanation of these breaks in the cable, but Prof. M. Ewing expressed confidence that these intuitive criticisms would prove incorrect. Prof. Ewing also mentioned that turbidity currents are not only confined to the regions of steep slope but are also found to exist on slopes as low as 1 in 500, and samples of undisturbed sedimentation can be obtained most satisfactorily on submarine hills of, for example, three thousand feet in height and five miles across. Prof. Kuenen later in the discussion noted that the turbidity currents are unable to cause erosion since they are in general overloaded, although they tend to be channelled down existing canyons. There is, he believed, no single origin from the submarine canyons, and they cannot all have been formed by subaerial erosion.

Prof. F. P. Shepard gave further evidence for the existence of turbidity currents from submarine canyons along the Californian coast. The Scripps Institute has particularly good opportunities for studying these canyons in shallow water, for at La Jolla there is one within five minutes sailing from the laboratory. Sediments are deposited in these canyons, and about every eight months the amount becomes unstable and disappears seawards. It is probable that small earthquakes can initiate this process. The material is undoubtedly transported to the deep water since, for example, foraminiferal material of shallow-water origin exists at the mouth.

Straightforward slumping cannot account for the transport, since the material is not uniformly layered in the area of deposition, and turbidity currents are the only explanation. Prof. Shepard agreed that these currents, while of primary importance in keeping the canyons clear, cannot account for their origin since their powers of erosion are inadequate.

Dr. J. D. H. Wiseman spoke of methods by which the climatic changes of the past can be detected in undisturbed deep ocean sediments. The first method is that of determining the total quantity of planktonic foraminifera in any level of the core by measurement of the percentage of carbon dioxide. These foraminifera act as temperature indicators rather than as indicators of the food supply, as is shown by their absence from antarctic waters, and consequently the quantity of carbon dioxide deposited depends directly on the temperature. Another method of determining the temperature depends upon the proportions of warm-, temperate- and cold-water forms of foraminifera found at any level in a deep-sea core, and a third method is the measurement of the proportion of the oxygen-18 isotope. This last method, which has been developed by Prof. H. C. Urey in Chicago, has been checked by investigations of Recent sediments. Dr. Wiseman showed there is agreement between the oxygen-18 and the carbon dioxide maxima down the length of a core. The rate of sedimentation of a core can be obtained by assuming that the rate of sedimentation of iron or titanium is constant and that, as would be expected on this hypothesis, there is a reciprocal relationship between the ferric oxide content and the carbon dioxide content.

Mr. B. C. Browne described the gravity results obtained by himself and those obtained by Prof. Vening Meinesz in the eastern Atlantic and in the English Channel. The scatter in the regional isostatic gravity anomalies is considerably greater in the deep water than in the shallow, the mean value for the Atlantic being + 11 ± 19 mgal. in comparison with + 7 ± 10 mgal. in the Channel. This increase in variation in the ocean can probably be associated with changes in the sedimentary thickness such as have been found by seismic refraction shooting. Mr. Browne considered that the rugged topography found in some areas is caused by the basement rocks protruding through pools of sediment, and he urged that there should be a combination of seismic and gravity observations to determine the extent of the association between the anomaly variations and the sediment thickness.

Dr. G. P. Woollard and Dr. J. L. Worzel agreed that many of the gravity anomalies at sea can be accounted for by the variations in sediment thickness and gave as known examples the sediments which accumulate in the depressions caused by elastic bending of the crust around oceanic volcanoes, the sedimentary layers of the continental shelf, and the great thickness of sediments found in the Puerto Rico Trench. Prof. Ewing later reported that, owing to the great magnitude of this thickness, attempts at measurement have three times failed. It may be deduced, however, that it is at least 9 km., which is enough to satisfy the gravity field, and for this reason it appears that there is no deep root of lighter rock such as is required by the Vening Meinesz theory of the formation of geosynclines. Dr. Woollard said that the association between sediment thickness and gravity anomaly does not always exist on the continents, and gave an example of a trough filled with sediments denser than the surrounding rocks, which nevertheless possesses a large negative free-air gravity anomaly.

Dr. J. L. Worzel described briefly the results obtained from six hundred gravity stations in the Atlantic, and explained that the common belief that the average free-air anomaly for the oceans is slightly positive is incorrect. If those stations at which the water depth is less than 3,000 m. and greater than 6,500 m. are rejected, the average free-air anomaly is − 3·2 mgal. The number of stations with a negative free-air anomaly was 258 and the number with a positive anomaly 195.

Prof. W. B. R. King described pebbles which have been obtained in cores in the eastern Atlantic in about the latitude of 50° N. These pebbles include several of basalt with the corners showing glacial scratches, some limestone pebbles with trilobite shell fragments, some coarse sandstones and mica schists. These, and the clay in which they were embedded, are all of glacial origin and indicate the importance of ice as a method of transportation of deep-sea sediments. How far this method extends to the south in the Atlantic is not known.

Dr. G. M. Lees objected to the prevalent concept of the oceans as static units and referred to the downwarping which has been known to occur and would sink the continental surface to oceanic depths. He said that he has no confidence in the deductions from the measurement of gravity at sea which lead to the belief in fundamental differences between oceans and continents, and, as an example of the uncertainty of interpretation of gravity results, he quoted measurements from north-west Africa where there is a discrepancy of 20,000 ft. between what is supposed to exist from the gravity results and what is found in seismic prospecting. The conception of the permanence of the oceans is so firmly thrust upon the geologists that they have arranged their interpretation to fit and have rejected any hypothesis which allows the extension of geological structures into the deep sea. Later in the discussion this last point was again raised, and it was apparent that geophysicists generally agree that the earth movements producing the continental surface features can extend without break into the oceans; an example of this is the continuation of the San Andreas fault for two thousand miles into the Pacific.

The session on the deep structure of the Atlantic was opened by Prof. M. Ewing, who outlined the areas investigated by himself and his colleagues by coring and seismic refraction shooting. These areas include the continental margin of the western Atlantic, the Caribbean area and the deep North Atlantic. All the deep stations have shown the same general structure for the earth's crust; it consists of about 5 km. of water overlying ½–1 km. of unconsolidated sediments, and below this there are 4–5 km. of crystalline rocks which are probably basaltic. This interpretation of material is based on the known compressional wave velocities and on the existence of olivine basalt on the mid-Atlantic ridge and islands. At the base of the basaltic layer is the Mohorovičić discontinuity, and below this the earth's mantle extends to great depths and is probably of the nature of peridotite. The work in the Caribbean indicates that, contrary to earlier beliefs, this sea is by nature representative of the deep sea and not of a sunken continent.

Sections across the continental shelf and slope show that the Mohorovičić discontinuity slopes upwards from about 200 miles inside the coast-line, where it lies at a depth of 30–40 km., to about 100 miles out to sea where, as under the deep ocean, it lies at a depth of 10–12 km.

The configurations of the layers lying above the Mohorovičić discontinuity are similar on all sections across the continental shelf and slope, although there are changes in the horizontal scale. They show the continental basement rock sloping seawards with wedge-shaped sedimentary layers lying on it.

Prof. Ewing next discussed the dispersion of surface waves in the sea bed produced in earthquakes. The information agrees with the theoretically derived dispersion for a layer of water overlying the rock and indicates a similarity of structure for the beds of the Atlantic and Pacific Oceans. In spite of the sediment thickness in the Pacific being half that of the Atlantic, this cannot be observed from the dispersion, and it is apparent that for these surface waves the sedimentary layer acts as water.

Dr. M. N. Hill showed the results he and Mr. A. S. Laughton have obtained with seismic refraction shooting in the eastern Atlantic during 1952. These, while small in number compared with those obtained by Prof. M. Ewing, confirm that the Mohorovičić discontinuity lies at a depth of about 11 km. below sea-level. Above this level the velocities are such as would be expected for basaltic rocks, and there is no evidence for the existence of any lower-velocity rocks between this layer and the base of the unconsolidated sediments. The sediments are variable in thickness; in some areas of rugged-bottom topography there appears to be none, and in other areas there is as much as 2·6 km. The average thickness is about 1 km. This thickness is greater than that found by Ewing in the western Atlantic, but the difference can, in part, be attributed to different assumptions concerning the velocity of compressional waves in the sedimentary layer.

A section from the central English Channel to the deep water of the Atlantic indicates that there is a slope of the basement rocks below the semi-consolidated sediments which is more gentle than that found by Bullard and Gaskell in a line farther to the north, and it suggests that the latter happens to coincide with an extension of the structure forming the south coast of Devon and Cornwall out towards the edge of the shelf. It is possible that this structural feature extends down the continental slope, since in this region the topography of the slope is exceptionally rough.

Dr. T. F. Gaskell described the three types of crustal structure which he and Mr. J. C. Swallow have obtained by refraction shooting in the Pacific Ocean during the recent world cruise of H.M.S. *Challenger*. It appeared that these three types are also to be found in the Atlantic. The first type is typical of the deep ocean and consists of about ½ km. of sediments lying on a layer in which the velocity corresponds to, although it is slightly lower than, the basaltic layers referred to by Ewing and Hill. The second type is similar to that of the deep ocean except that interposed between the sediments and the basement rock lies a layer in which the velocity is such as would be expected for volcanic material. This interpretation is supported by the existence of volcanic islands and sea mounts in those regions where this succession is found. The volcanic cores themselves are such that the velocity of compressional waves is similar to the basement rock. The third type, which is typified by stations on the landward side of the andesite line, shows basement velocities less than those in the other types and similar to those in the continental surface layers.

The Atlantic results of H.M.S. *Challenger* were mostly in the Bermuda region, and these show the second type of structure. The sea depth is about 5 km., and the unconsolidated sediment depth ½–1 km. Below the sediments there are lavas 1½–2½ km. in thickness lying on the basement rock. There is only one result from the Atlantic which belongs to the deep ocean type.

Prof. J. P. Rothé described the distribution of recent earthquake epicentres in the Atlantic and Indian Oceans and the Mediterranean Sea. The line of activity extended from the Red Sea to the Carlsberg Ridge and thence to the south of the Cape of Good Hope, joining with the mid-Atlantic ridge which passes northwards through Tristan da Cunha, St. Paul's Rocks, the Azores and thence to Iceland. The Mediterranean line of earthquake activity extended westwards as far as the mid-Atlantic ridge. Within the area roughly bounded by these lines of activity there are continental rocks, and outside there exists the typical oceanic structure. Prof. Rothé suggested that perhaps there is not the clear-cut distinction between the velocities of compressional waves in the continental type of surface-rocks and those in the basaltic layer. In support of this, he quoted an example on land where there is an obvious and typical continental surface and yet giving high velocities which Ewing associated with basaltic rocks. In spite of the evidence from seismic experiments at sea, it is therefore still possible that the sialic rocks form the sea bed below the sediments within the area bounded by the earthquake belts. This hypothesis is supported by the velocities of surface waves from earthquakes which traverse this area.

Prof. H. H. Hess stated the importance of obtaining pieces of rock from below the Mohorovičić discontinuity and believed it to be not impossible that these would be different if obtained from under the continents rather than from below the oceans. Peridotitic bombs from oceanic volcanoes probably represent the material of the mantle, although it is possible that they are aggregations from basaltic rocks. It is also probable that the periodotites obtained from St. Paul's Rocks are representative of the layers below the Mohorovičić discontinuity.

Prof. Hess discussed the problem of guyots. He explained that, contrary to previous suppositions, their top surfaces were all of later origin than pre-Cambrian, and these surfaces must have sunk many thousands of feet below sea-level in post-Palæozoic times. This is demonstrated by the existence of Cretaceous and Eocene fossils in the surface layers. He believed the Pacific guyots, which lie on lines, represent the upward edge of convection cells in the earth's mantle and that the island arcs represent the downward edge.

Dr. E. C. Bullard described the significance of the measurements of heat flow which are being made at sea. On land, measurements have been carried out for many years in mines and boreholes and have demonstrated that, within a factor of 2, the value of the heat flow is $10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$. This heat flow is commonly supposed to be accounted for by the radioactivity of the continental surface rocks. Hence, it was deduced that the heat flow under the oceans would be less and that this differential heating between the oceans and continents could account for convection currents in the mantle and thereby many of the earth's structural features. Measurements by Maxwell and Revelle in the Pacific, and by Bullard in the eastern Atlantic, have shown that these conclusions are incorrect, the heat flow for the Pacific being roughly equal to the continental value and that for the Atlantic being slightly less and about 0·7 times the continental value; the expected heat flow, on the old hypothesis, was about 0·25 times the continental value. Explanation of this value for the heat flow is difficult, but might be accounted for by the total quantity of radioactivity in any vertical column being independent of the location of that column, in the same way as there is an equality of mass between columns.

In reply to a query by Dr. Lees concerning the heat flow from the oceans and continents being approximately the same, Dr. Bullard expressed the firm belief that this does not indicate that continents could have existed where now there are oceans, since the measured differences in structure are too great. There is, however, the irreversible possibility of continents extending into regions where there are now oceans. M. N. Hill

# HATHERLY BIOLOGICAL LABORATORIES, UNIVERSITY COLLEGE, EXETER

By Prof. JOHN CALDWELL

On April 23 the Hatherly Biological Laboratories of University College, Exeter, were formally opened by Sir Edward Salisbury, director of the Royal Botanic Gardens, Kew, in the presence of a gathering representative of the universities and learned societies, as well as of local and national bodies. In his address on the "Place of Biology in the University Curriculum", Sir Edward dealt with the value of the discipline of biology in a liberal education and the part that universities can play in developing a broader and more general approach to the whole subject of biology and its implications, deploring the narrow specialization which tends to isolate the biologist, and not only biologists, from the sympathy and understanding of the community. The chair was taken in the absence of the president, the Most Hon. the Marquess of Salisbury, by the deputy president, Mr. B. G. Lampard-Vachell. The thanks of the company to Sir Edward Salisbury was expressed by the principal of the College, Sir Thomas Taylor. Thereafter, before the company moved off to inspect the laboratories and the demonstrations set out in them, a brief account of the building was given by Prof. J. Caldwell, director of the laboratories. Plans were prepared for the laboratories after the College received a bequest from Mrs. Ellen Heath, of Exeter, towards the erection of a building to be associated with the name of Hatherly. The additional money was obtained through the generosity of the University Grants Committee, and the foundation stone was laid by the president of the College on July 28, 1948 (see *Nature*, **162**, 505; 1948).

The laboratories, which were built to the design of Mr. E. Vincent Harris, consist of a central block with entrance hall and private rooms for members of staff and two wings facing south-east. From this there project to the west five bays, each two stories high, with the main laboratories in them. The advantage of this arrangement is that the north-facing sides of the laboratories are almost completely of glass, plate-glass sheets 11 ft. by 7 ft. in the lower floor and 7 ft. square on the upper. These ensure that there is excellent natural light in the laboratories and the orientation of the laboratories shields these windows from direct sunlight.

Three Departments are housed in the building—Botany, Geology and Zoology. The first has two large junior laboratories each approximately 60 ft. by 30 ft., and one advanced laboratory 60 ft. by 25 ft.; the two former have preparation and store rooms attached. The mycology laboratory, with an annexe as a sterilizing room, is 30 ft. by 25 ft., as is the lecture room above it and a fifth laboratory and reading room above that. These are in the wing to the front of the building on the south side. There are, in addition, private laboratories for the members of staff, an office and three research laboratories roughly 20 ft. square. The Department of Zoology has its laboratories in the third and fourth bays. There are two laboratories, one on the ground floor and one on the upper floor, and a series of research

Hatherly Biological Laboratories. Main laboratories with north lights

Hatherly Biological Laboratories. Central block

rooms for members of the staff and postgraduate students. The Department also has in the north wing to the front of the building a small animal room, an aquarium room (corresponding to the mycology laboratory in the other wing), a lecture room and a laboratory equipped for physiology.

The Department of Geology, which, though new, is rapidly developing, has one large laboratory and research and private rooms. The fifth bay has on the ground-floor the lecture-theatre, which accommodates 110, and above that the museum–reading room, common to all three Departments. In addition, there are dark-rooms, constant-temperature rooms with controlled humidity and temperature, a workshop and store-rooms. Provision has been made for a resident caretaker and for a technician.

The exhibits included, in the Department of Botany, herbarium material of Devon plants, especially of Dawlish Warren, and a collection of floras and books dealing with them. There was also a representative collection of Coniferæ from the College arboretum. Cultures and material illustrating the survey of animal mycoses being undertaken with the support of the Agricultural Research Council by Dr. G. C. Ainsworth and Mr. P. K. C. Austwick were on show, as was material dealing with chrysanthemum, broccoli and narcissus virus diseases, with a range of host plants, and cytological studies of the nuclear aberrations which are associated with them. This work is carried out by Prof. J. Caldwell, Dr. J. Wilkinson and Mr. D. A. Govier. There was a very extensive collection of drawings and photographs illustrating the larger fungi of sand dunes, the ecology of which is being studied by Mr. T. J. Wallace. Further material illustrated Dr. T.-T. Chan's work on the developmental morphology of the narcissus plant, and there was in addition a laboratory devoted to specimens of the current work of the undergraduate members of the Department.

In the Department of Geology there was displayed material illustrating the work being carried on, which includes Mr. A. Stuart's study of the Pleistocene of the Bideford Bay area, and of the terraces of the Lower Exe Valley and the petrology of the Carboniferous Igneous Rocks of Bantry Bay, Ireland. Dr. D. L. Dineley is working on the geology of a part of Spitsbergen and on the Conodonts and Ostracoderms of the Devonian and Carboniferous rocks of the south-west, and of the Welsh Border, while Dr. R. N. C. Bowen is studying the Foraminifera and Ostracods of the Tertiary rocks.

In the Department of Zoology exhibits illustrated Dr. R. J. S. Hawes's work on the parasitic Protozoa of invertebrates, Mr. G. G. Vicker's studies on the ticks of south-west England and Mr. I. J. Linn's studies on the ecology of small mammals. In addition, there was material representative of Mrs. C. Harvey's work on fertility problems and Miss R. A. Manwaring's ecological studies on the fauna associated with certain marine algæ. Further material illustrated Mr. M. J. Delaney's taxonomic and ecological studies on the Thysanura, Mr. P. D. Gabbutt's ecological study on the wood cricket and Prof. L. A. Harvey's ecological survey of Lundy.

# RELATION OF ADRENOCORTICOTROPHIN (ACTH) TO THE MELANOPHORE EXPANDING (B) HORMONE OF THE PITUITARY*

By Prof. H. WARING and B. KETTERER†
University of Western Australia

TWO laboratories[1,2] have recently claimed that adrenocorticotrophin (ACTH) is identical with the melanophore-expanding hormone (B) of the pituitary. This claim has obvious academic interest; but it also raises an issue of importance for those concerned with research technique and clinical practice, because the assay for melanophore-expanding properties is simple and reliable[3], while the currently used ACTH assays are not.

Consideration of this claim demands, as a preliminary, a brief survey of the relevant information about both excitants.

## Adrenocorticotrophic Hormone(s)

Information from hypophysectomy, injection of extracts, and clinical observation shows that the pituitary in mammals controls adrenal cortical size, lipoid distribution, ascorbic acid content and, indirectly through the release of cortical steroids, it controls eosinophil numbers and lympholytic activity[4]. We do not know whether all these effects are mediated by one hormone (ACTH) manufactured in the gland, or by several. In particular, we do not know the significance, if any, of ascorbic acid depletion in relation to steroid release. It is important to emphasize this because ascorbic acid depletion has been arbitrarily chosen as the popular assay for ACTH activity and by sheer weight of words has become almost synonymous with it, to some people. It is certain that, by various procedures, extracts can be produced with one or other activity preponderant. So without further consideration the question before us must be more precisely phrased as: Is B hormone identical with all, or only part of the totality of ACTH, or entirely independent of it?

With regard to the seat of origin, cytological evidence[5] is sufficient to show that the anterior lobe of the pituitary is involved; but we have found no evidence based on surgery to show that the intermediate lobe is not involved and, in this context, we note that the pituitary grafts which have maintained the adrenal with greatest success have contained intermediate lobe as well as anterior lobe of the pituitary[6].

A considerable amount of work has been done on the chemistry of ACTH. In 1943 Li *et al.*[7] and Sayers *et al.*[8] independently prepared similar proteins which exhibit ascorbic acid-depleting, adrenal cortical size-maintaining and other properties. These proteins appeared pure when judged on physico-chemical criteria, and for some time it was thought that they were the adrenocorticotrophic hormone. However, biological assay of the Li preparation showed 0·02 I.U./mgm. pressor activity[7], and the International Standard powder (ACTH), which is prepared similarly, contains 0·35 I.U./mgm. B activity[9]. So it appears that the 'pure protein' contains contaminating material of considerable biological potency but insufficient in bulk to manifest itself in physical determinations for purity.

Some and perhaps all ACTH activity in simple extracts, or in purified protein, is relatively stable to partial hydrolysis with hydrochloric acid and pepsin. In 1948 Li[10] demonstrated that in digested extracts the ascorbic acid depleting activity resided in a peptide. Attempts to purify the peptide activity have resulted in material with up to 300 times the ascorbic acid depleting potency of standard powder[11]. A similar preparation of Lesh *et al.*[12] had an average molecular value of between 2,500 and 10,000. The isolation of a large molecular peptide material with such a high potency suggests that the activity of the 'protein hormone' might simply be due to slight adsorbed contamination with material of this type. Dr. Stanford Moore's work, as recorded by Stack-Dunne and Young[13], is consistent with this. Moore subjected Sayers's protein to ion-exchange column chromatography and got a separation into a major component, acid and inert, and a trace component, basic and very potent. (The alternative proposition, that a molecule such as Brink's, which we have assumed has a molecular value similar to Lesh's preparation, is actually a part of the parent molecule and is released by various procedures, would mean that weight for weight its activity must be increased at least 30 times by the simple act of separation. Furthermore, one would expect at least a 10 per cent yield of such an activity, but Stanford Moore's experiment produced it only as a trace (on a weight basis).) Apparently oxycellulose is another adsorbent which can separate ascorbic acid depleting activity from the protein. Li and his associates[14], by a combination of adsorption and chromatography with oxycellulose, have obtained a basic material within the same activity range as Lesh's and Brink's fractions. When this material was hydrolysed, only eight different amino-acids were found in the hydrolysate.

In all this recent work, adrenal ascorbic acid depletion has been used for measuring ACTH activity and at present it appears highly probable that total ACTH activity is dependent upon more than one chemical entity. Thus Reinhardt and Li[15] found that when a protein ACTH preparation was subjected to peptic hydrolysis its ascorbic acid depleting activity was doubled, adrenal weight increasing activity reduced and its lympholytic activity increased several fold. When an acid hydrolysate was used and the undigested protein removed, the ascorbic acid depleting activity was greatly increased and the adrenal weight maintaining activity was greatly reduced. An even more striking separation between two activities considered to be adrenocorticotrophic has been reported by Stack-Dunne and Young[13]. They prepared crude alkaline extracts of anterior lobe and purified growth hormone with adrenal weight maintaining/ascorbic acid depleting ratios up to 5,000. It could be objected that an interpretation of separate chemical entities for each biological activity must be treated with caution because changes in the physical aggregation of injected material can modify the several responses differentially. Hayashida and Li[16] showed that precipitation of protein preparation in alum solution increased both adrenal weight and lympholytic activity twofold; similar precipitation of a peptide increased the lympholytic activity several fold, but the adrenal weight activity remained unchanged. However, this type of phenomenon could scarcely account for the result of the Stack-Dunne and Young fractionation.

### Melanophore-expanding Hormone (B)

In colour-changing vertebrates, notably Amphibia, there is completely satisfying evidence that a hormone (B) is produced in the intermediate lobe of the pituitary, and its liberation into the blood-stream evokes darkening of the skin[17] both by expanding melanophores and potentiating the formation of more melanin; there is new unpublished evidence that the presence of endogenous B antagonizes adrenalin hyperglycæmia in intact toads[18]. In warm-blooded animals that do not change colour, B hormone, although present, has not so far been shown to subserve any function, although experiments at the pharmacological level show that in these animals also it has anti-adrenalin properties[19] and there is a *prima facie* case for further investigation of its potential role in hyperpigmentation.

There has been no comparable systematic work on the chemistry of B to parallel that on ACTH outlined above. There has, however, been work at the pharmacological level and the relevant parts of this are considered below.

### Is B Identical with the Totality of ACTH or Part of It ?

There is factual information only for assessing whether or not B is identical with ascorbic acid depleting activity; any attempt to equate B with total ACTH, or another part of it, is pure speculation. Even for consideration of this more limited objective there is a major qualification to all the points that can be made in favour, or against, the proposition. There is evidence[20] for some pituitary control of cortical tissue in Amphibia, but there is, as yet, no information about the measurement of ascorbic acid depleting activity in these animals. Equally, ascorbic acid depleting activity can be measured in mammals, but no measurement of B activity can yet be made in them. Until this is resolved—and it is probably resolvable—there will always remain the doubt as to whether the same molecule will have comparable biological effects in the two animal groups. This suspicion is not just fanciful. A number of discordant data from posterior lobe studies are most plausibly explained in this way and, more specifically to our present problem, although there is ample evidence for some ACTH control of cortical activity in birds[21], pituitary extracts containing mammalian ascorbic acid depleting activity have no effect on the ascorbic acid content of bird adrenals[22]. With this qualification, the relevant data are here assessed:

(*a*) The only parallel assays on separated pituitary lobes which have been performed with the intention of showing whether or not B measured in Amphibia, and ascorbic acid depleting activity measured in mammals, have a separate origin are those of Reinhardt *et al.*[23] on the anterior and intermediate lobes of *Rana catesbiana*. These assays show that activity which depletes the rat adrenal of ascorbic acid is more concentrated in the anterior lobe than in the intermediate lobe and vice versa for B activity.

(*b*) Sulman[24] reported a rise of both ascorbic acid depleting and B activities in the blood of human patients exhibiting hyperpigmentation, Cushing's syndrome, Addison's disease, pregnancy, and operational stress, etc. Johnsson and Hogberg[1] give similar information. According to the authors, this evidence shows that B activity stimulates the adrenal cortex on the basis of the well-known check-balance system of pituitary excitants with their target-organ secretions, but another interpretation is possible. The relationship of the pituitary to its various target organs is not a simple one, and the following well-known examples show that a pituitary hormone is sometimes affected by steroids not under the control of that particular pituitary excitant. (i) The adrenal cortex secretes minero-corticoids (of deoxycorticosterone acetate type—DCA) and gluco-corticoids (of cortisone type). ACTH stimulates chiefly gluco-corticoid release, and hypophysectomy does not inhibit minero-corticoid production. Yet injections of DCA, as well as cortisone, inhibit the release of ACTH[24]. (ii) Œstrogen injections potentiate melanogenesis correlated with hyperplasia of the intermediate lobe[25], but B is not gonadotrophic. (iii) Castration increases pituitary antidiuretic hormone (ADH)[26], but the latter is certainly not gonadotrophic.

(*c*) Both B and ACTH, unlike other pituitary hormones, are heat stable over a wide *p*H-range, and both are more stable to peptic than tryptic digestion[17].

(*d*) Johnsson and Hogberg[1] found that both B and ascorbic acid depleting activity occupied the same position on a paper chromatogram using the phenol/water solvent system. This is not a specific test, since a number of proteinaceous substances behave similarly[27].

(*e*) Sulman[28] was able to get a melanophore response to 0·01 gamma of a commercial 'ACTH' preparation. He argued that such high activity could not be due to a contaminant; but actually a preparation need only contain 0·3 per cent by weight of a peptide like that of Brink *et al.* to be as active as standard powder in ascorbic acid depleting activity. The only kind of investigation along these lines which will have any real meaning is a series of parallel ascorbic acid and B assays on a quantitative basis. Reinhardt *et al.*[23] have done this, although they do not give any information which enables us to assess the reliability of their B assay technique; no correlation between the two activities was found.

(*f*) Reinhardt *et al.*[23] state that caustic soda treatment destroys ascorbic acid depleting activity but increases B activity (potentiation). This is a generalization which requires further comment. Material prepared by adsorption on to, and elution from, charcoal or oxycellulose (which would remove much protein), when treated with caustic soda, loses both ascorbic acid depleting activity and B activities at a similar rate. On the other hand, if a simple pituitary extract, or material which has been purified by *some*, but not all, fractional precipitations, is treated with caustic soda, its B activity is potentiated and its ascorbic acid depleting activity is destroyed. This B-potentiation is only shown by Amphibia which have been in use a short while; those which have been in use longer give the same response to caustic soda treated extracts as they would to untreated extracts[20]. It appears that, in the presence of pituitary protein, B activity is protected from destruction by alkali, and further, that an extra activity is produced which is detectable only by Amphibia which have been in use a short time. This seems clear evidence that B and ascorbic acid depleting activity are not referable to an identical configuration. The new observation[9] that when *Xenopus* has become insensitive to potentiated B from posterior lobe pituitary extracts it still reacts to potentiated B in ACTH extracts will inevitably lead to speculation about the possibility of a hydrolysate of ACTH having melanophore excitant properties, but such speculations are premature.

(g) Morris[29] claimed that Landgrebe and Waring methods for obtaining B by carbon adsorption eliminated the ascorbic acid depleting activity. We cannot confirm this, nor can Reinhardt *et al.*[23].

(h) Deliberate attempts have been made to bring about a complete separation of B and ascorbic acid depleting activity. Morris[29] used counter-current distribution, and Reinhardt *et al.*[23] used oxycellulose column chromatography and filter paper electrophoresis; the separations achieved were substantial but not complete.

## Conclusion

From the foregoing, B and ascorbic acid depleting activities appear chemically similar but are separable in certain circumstances. This probably means that these activities reside in different molecules in the gland and bear a close but fortuitous chemical relationship; their apparently different anatomical origin, and in particular the evidence from *Rana*, are consistent with this. However, even if B is not identical with ascorbic acid depleting activity, the evidence to date neither favours, nor precludes, B from a part in the pituitary adrenocorticotrophic system which appears to be complex.

# NEWS and VIEWS

## Prof. R. Courrier, For.Mem.R.S.

Prof. Robert Courrier is a graduate in medicine and in natural science of the University of Strasbourg, of which he became a member after serving in the front-line throughout the better part of the First World War. Bouin was then the head of the Department of Histology, and Ancel of Embryology, and Courrier was among the first of a distinguished line of investigators whose work derives from the union of interests of these two great pioneers of the scientific study of the physiology of reproduction. In 1927 he went to Algiers, where he was given charge of histological teaching in the Faculty of Medicine. He became a full professor in the Faculty in 1936, and two years later was invited to the Collège de France as professor of experimental morphology and endocrinology. Appointments to the Collège are not determined by the interests of previous holders of chairs, and new professors are chosen, essentially as research professors, on the basis of their eminence in the field of study they pursue. In the fifteen years since he has been in Paris, Courrier has established a magnificent department which is known to endocrinological research workers throughout the world. In 1941 he was made a member of the Academy of Medicine, and in 1944 of the Academy of Sciences. Election to the foreign membership of the Royal Society is the most recent of a series of national and international honours which he has received.

Courrier's first work was concerned with the control of secondary sexual characters in mammals, and with the regulation of the oestrous cycle, and his early papers reveal a maturity and an originality of approach which have continued to mark all his subsequent work. After some very detailed studies of reproduction in the cat, Courrier took the opportunity offered by his post in Algiers of extending his inquiries to the monkey of North Africa, *Macacus inuus*—a species which he is still investigating in his Paris laboratories. Among the many original observations dating from this period was his demonstration that the epithelium of the uterus masculinus in the male monkey responds to oestrogen in the same way as does the vaginal epithelium in the female—a discovery which was simultaneously reported in Great Britain and the United States, and which forms the basis of many of our present ideas about homological relations between the male and female reproductive organs. About this time, Courrier also became greatly interested in the functional and quantitative aspects of the synergism and antagonism of androgenic, oestrogenic and progestational hormones. As a result, his attention became focused more and more on the biological properties of the corpus luteum, and on the endocrinological factors which underlie the changes of gestation. A book he published on this subject in 1945 remains one of the most valuable and up to date on the subject. More recently, Courrier has become interested in the properties of a variety of synthetic chemicals which reproduce the behaviour of biological hormones; and he has also used radioactive substances in the study of hormonal action.

Courrier's considerable output of scientific work has not prevented him from playing a big part in scientific administration, and his election in 1948 to the office of Secrétaire Perpétuel of the Academy of Sciences not only reflects the favourable light in which the administration of his own Department is viewed by his colleagues, but also the impetus which, as a member of the Conseil supérieur de la Recherche Scientifique, he has given to the post-war development of French science. Men of science outside France will remember with gratitude the lead he has taken in organizing international colloquia at the Collège de France on various subjects, especially those relating to the physiology of reproduction.

### Dr. H. J. Muller, For.Mem.R.S.

Another distinguished man of science who has just been elected a foreign member of the Royal Society is Dr. H. J. Muller. Hermann Joseph Muller was one of the three collaborators of T. H. Morgan whose co-ordinated experiments on *Drosophila* between 1910 and 1916 established the chromosome theory of heredity. Muller was especially responsible for working out the principles of crossing-over between chromosomes or strings of genes, principles now believed to be universal in sexually reproducing organisms, extending even to bacteria and viruses. In 1927 Muller perfected the measurement of spontaneous mutation which enabled him to prove the effect of temperature. It also enabled him to prove the effect of X-rays. Muller's method first made it possible to show that mutations had been induced, and that those, therefore, which were apparently 'spontaneous' might in fact be regarded as determined. It revolutionized genetic technique by providing an artificial source of variation in any organism where it was needed. It led to the discovery that chromosomes could be broken and recombined, first by ionizing radiations and later by chemical reagents, a discovery equally important in plant breeding and cancer research. This work put the study of genes, chromosomes and evolution on an experimental basis. In all the developments which followed, Muller has taken a leading part. Of the greatest importance have been his examination of the genes as units of physiological action and of X-ray breakage, his analysis of the physiological properties of different classes of mutations, his demonstration of the existence of 'inert' genes, and his physiological interpretation of Fisher's theory of dominance. Muller's discussions of the theory of genetics are no less significant than his experimental work. He first suggested the importance of chromosome balance in sex determination. He first (in 1918) showed how the mutations of *Oenothera*, on which De Vries's theory of evolution was based, could be regarded as due to Mendelian segregation, an explanation established in the following fifteen years. He first (in 1921) pointed out the analogy between virus and gene and its practical significance. Briefly, Muller's work and ideas, always in advance of the times, moulded the development of genetics in the critical years between 1916 and 1936, and it was in recognition of this achievement that he was awarded the Nobel Prize for Medicine in 1946.

### Directorship of the Meteorological Office: Sir Nelson Johnson, K.C.B.

The Air Ministry has announced that Sir Nelson Johnson is to retire in the autumn from the post of director of the Meteorological Office. Sir Nelson received his scientific training at the Royal College of Science, London, joined the Meteorological Office in 1919 after war service as a pilot, and formed the new meteorological office at the War Office Chemical Defence Research Establishment at Porton in 1921. The investigation at Porton of the meteorology of the lower layers of the atmosphere gave full scope to his capacity for experimental research; he devoted himself especially to the vertical gradient of temperature, devised new methods for its measurement, and, in Geophysical Memoirs 46 and 77 of the Meteorological Office and elsewhere, he published work which has become classic in this field. He left the Meteorological Office in 1928 for service in the War Office, and in September 1938, on the retirement of Sir George Simpson, returned to the Meteorological Office as director. The Second World War brought a large expansion in the work and size of the Office and a corresponding increase in the director's responsibilities. In spite of a heavy load of day-to-day administration, Sir Nelson continued the planning, begun in 1938, of a new research organization for meteorology, and in 1941 the Air Ministry Meteorological Research Committee was set up. After the War he carried out a major reorganization of the Meteorological Office, including the setting-up of the planned research organization. In 1946, at the first post-war international conference on meteorology, he was elected president of the International Meteorological Committee, and in that capacity he presided over the Washington Conference of Directors in 1947, which established the Convention of the World Meteorological Organization; in 1951 he became the first president of the new Organization. Great progress in meteorological organization has been made under Sir Nelson's guidance and his services were recognized by the award of a K.C.B. All who have served under Sir Nelson, either in British meteorology or in the international field, will wish him good health during his retirement for many years to come so that he can actively pursue his many and varied interests.

### Prof. O. G. Sutton, C.B.E., F.R.S.

Prof. O. G. Sutton, at present dean and Bashforth professor of mathematical physics in the Royal Military College of Science, Shrivenham, who has been appointed to succeed Sir Nelson Johnson, is an expert of world-wide authority in the dynamics of the lower atmosphere. He graduated in mathematics from the University College of Wales, Aberystwyth, and was a lecturer there before joining in 1928 the staff of the Meteorological Office. He was posted to Porton in 1929 and soon showed his powers by his work on the mathematical theory of turbulent diffusion in the atmosphere. In 1942 he was appointed superintendent of research in chemical defence at Porton, and during 1943–45 was superintendent of tank armament research. He went to the Radar Research and Development Establishment in 1945 as chief superintendent and in 1947 was appointed Bashforth professor in the Royal Military College of Science. He was scientific adviser to the Army Council in 1951, and is now chairman of the Atmospheric Pollution Research Committee of the Department of Scientific and Industrial Research, as well as serving on other meteorological committees. Prof. Sutton has written a large number of papers on the structure of the lower atmosphere and turbulent diffusion and their applications to such practical problems as evaporation from free water surfaces and the dispersion of smoke from factory chimneys. His recently published text-book, "Micrometeorology", is an exhaustive survey of knowledge on the atmosphere at breathing level. He was elected to the Royal Society in 1949 and awarded a C.B.E. in 1950.

## Royal Meteorological Society: Symons Memorial Medal Award

THE Symons Memorial Gold Medal for 1953 of the Royal Meteorological Society has been awarded to Prof. Carl-Gustav Rossby, director of the Meteorological Institute, University of Stockholm, and lately professor of meteorology in the University of Chicago, in recognition of his outstanding contributions to meteorology. The citation states: "He has placed his permanent impress on the fundamental branches of the science from the small-scale turbulence of the lower atmosphere to the dynamics of the large-scale currents and their relation to the general circulation of the atmosphere. We esteem Professor Rossby most of all perhaps for the vigorous lead he has given to scientific meteorological research and for his inspiration and encouragement of meteorologists in all parts of the world".

## Diffusion of Knowledge

SPEAKING in Washington on February 13 at a dinner given in his honour, Dr. L. Carmichael, the incoming secretary of the Smithsonian Institution, referred to the tribute which had been paid by Americans on January 16, 1879, to the memory of the first secretary of the Institution, Joseph Henry, who had died eight months previously. That tribute to a great scientist was also a unique official tribute to science itself; but nevertheless Dr. Carmichael wondered whether any real progress has been made in the past seventy-five years in diffusing an understanding of science. In a farewell address to the American Philosophical Society in 1796, Washington had urged, as an object of primary importance, the promotion of institutions for the general diffusion of knowledge, adding that, in proportion as the structure of a government gave force to public opinion, it is essential that public opinion should be enlightened. James Smithson, in bequeathing his property to the United States of America for the founding of the Smithsonian Institution, defined it as "an establishment for the increase and diffusion of knowledge among men", and Andrew Carnegie, who for many years placed the motto "Let there be light" in all the libraries he established, is said to have believed that enlightenment is the one general remedy for the ills that beset the human race. Although pure and applied science to-day find unequalled public and private support in many sections of the nation, Dr. Carmichael believes it is still necessary to defend research expenditure by referring to the immediate practical utility of the investigations. We still need a society for propagating the understanding of the true place of science in society. The great human advantages which the world would derive through the proper support of science must be told and told again in clear and popular language. Washington, Smithson and Carnegie envisaged a happy marriage between research and public information, and Dr. Carmichael thinks that scientists should see that neither selfishness nor inertia prevents their participation in the task of interpreting science to the millions and assisting the expert science writers in a task to which they have already brought intelligence, enthusiasm and dedicated service.

## *Journal of Rational Mechanics and Analysis*

IN the first four numbers of a new quarterly, the *Journal of Rational Mechanics and Analysis* (published by the Graduate Institute for Applied Mathematics, Indiana University, Bloomington, Ind.), there are, in all, some twenty papers running to about six hundred and fifty pages of print, and it is now possible to review the *Journal* during the first year of its existence. The editors are Profs. T. Y. Thomas and C. Truesdell, and the eminent editorial board, numbering twenty-six, is drawn in about equal proportions from United States universities and institutes of technology and from the corresponding institutions in various countries of western Europe. The purpose of the *Journal*, as stated on the inside front cover, is "to close the rift between 'pure' and 'applied' mathematics and to foster the discipline of mechanics as a deductive, mathematical science in the classical tradition. Its scope comprises those parts of pure mathematics or other theoretical sciences which contribute to mechanics; among the included fields are all branches of analysis, differential geometry, analytical dynamics, elasticity, fluid dynamics, plasticity, thermodynamics, relativity and statistical mechanics. Engineering applications, numerical work, perturbation procedures, etc., are acceptable only as incidental illustration in a paper devoted to sound mathematical theory". The papers published to date are fully consistent with this point of view, being primarily pure mathematical in character and outlook, and having the explanation of natural phenomena as but a secondary objective. In this respect, the *Journal* is in marked contrast to the *Quarterly Journal of Mechanics and Applied Mathematics* (Oxford University Press). That there is a place for the publication of papers of the kind just described is beyond doubt, but the extent of the interest which such papers are likely to arouse is open to question. With regard to subject-matter, there have so far been nine papers on fluid dynamics, three on elasticity or plasticity, one on relativity and one on analytical dynamics, while the remaining six have ranged over a wide variety of topics. The subscription price of the *Journal* is 6 dollars a volume for individuals engaged in research or teaching, but 18 dollars for everyone else; by British standards, the latter figure is distinctly high.

## Recruitment of Scientists and Technologists in Great Britain

IN reply to a question in the House of Commons on April 28, the Chancellor of the Exchequer, Mr. R. A. Butler, stated that the number of scientists and technologists coming from the universities and technical colleges of Great Britain with degrees, Higher National Certificates and Higher National Diplomas, or their equivalent, during the academic year 1951–52 was estimated to be one in about 2,600 of the population. Mr. Butler added that the Government is doing its best to improve the facilities for technological education; he concurred with the suggestion that there is still great difficulty in persuading engineering and other firms to employ the scientists and technologists in the works, and that industry requires a great deal more encouragement to make use of the highest and best form of knowledge.

## A Model Rehabilitation and Training Centre

IN May 1952 the President of the Austrian Republic performed the opening ceremony of what is probably the finest rehabilitation and training centre to be found in Europe. It is situated at Tobelbad, about nine miles from Graz, and has been built on the site of a former spa (*Rehabilitation*, 7; January 1953). Extensive new buildings have been erected over the site of the hot springs affording ample accommodation for 250 patients as well as the staff of the centre. The centre is owned by the Allgemeinen Unfallversicherungsanstalt (United Accident Insurance Corporation). The Corporation's decision to establish this centre for the rehabilitation of accident cases occurring anywhere in Austria was largely influenced by the views of two young orthopædic surgeons who were members of the first rehabilitation course held in Great Britain under the auspices of the British Council. When completed, the training centre, which is directly connected to the rehabilitation centre, will be used for short courses of training in carpentry, metalwork, wood-carving, leather work, shoe-making, tailoring and dressmaking. It is not intended to use them for long or complete vocational training courses, such as are available in Government training centres, but rather as a means of giving both work therapy and vocational guidance to those undergoing physical and industrial rehabilitation before returning to their former employment or undertaking new courses of training.

### "The Behaviour of Engineering Structures"

Prof. A. J. S. Pippard writes: "In my article published in *Nature* of May 2, I made the statement that it was not until 1947 that exact theoretical solutions for the stresses in masonry dams had been obtained. It has since been pointed out to me that Dr. L. F. Richardson dealt with this subject in a paper entitled 'The Approximate Arithmetical Solution by Finite Differences of Physical Problems involving Differential Equations, with an Application to the Stresses in a Masonry Dam", published in *Phil. Trans.*, A, 210, 307 (1911). I regret that I overlooked this reference".

### Announcements

The Alexander Pedler Lecture of the British Association is to be given this year by Sir Harold Hartley; he will speak on "The Life and Times of Sir Richard Gregory". The Lecture will be given in the Royal Institution on May 28 at 6 p.m.; applications for tickets should be sent to the Secretary, British Association, Burlington House, Piccadilly, London, W.1.

The Council of the Royal Society of Edinburgh has awarded the Gunning Victoria Jubilee Prize for the period 1948–52 to Prof. A. C. Aitken, of the University of Edinburgh, for his distinguished contributions in the field of pure mathematics; and the Makdougall-Brisbane Prize for the period 1950–52 to Prof. E. M. Wright, of the University of Aberdeen, for his papers in the field of pure mathematics published within the period of the award in the Society's *Proceedings*. The Prizes will be presented by the president at the meeting of the Society on July 6.

Dr. Joseph Junkes, *S.J.*, has been appointed director of the Astrophysical Laboratory of the Vatican Observatory, in succession to Dr. Alois Gatterer; Dr. Ernest Salpeter, *S.J.*, is assistant director of the Laboratory. It is hoped that the first volume of the "Atlas of Molecular Spectra" ("Spectra of Diatomic Molecules, the Oxides"), undertaken by the Observatory at the request of the International Astronomical Union, on which Father Gatterer was engaged until shortly before his death, will be ready by the end of this year.

The Royal Sanitary Institute, in collaboration with the Ministry of Agriculture and Fisheries (Infestation Control Division), is organizing a rodent control exhibition, open to the general public, to be held in the Institute's Museum of Hygiene, 90 Buckingham Palace Road, S.W.1, during May 26–June 20 (Monday–Friday, 10 a.m.–5 p.m.; Saturday, 10 a.m.–noon).

A summer school in the use of electrons for the examination of metals will be held during July 20–31 in the Cavendish and Goldsmiths' Laboratories, University of Cambridge, in co-operation with the Institute of Metals. This will consist of lectures, demonstrations and practical classes in the principles of the electron microscope (including reflexion techniques) and electron diffraction camera and their practical applications to the study of metals. Application forms (to be returned by May 30) and further information can be obtained from G. F. Hickson, Secretary of the Board of Extra-Mural Studies, Stuart House, Cambridge.

Two interesting articles are contained in Vol. 1, Part 2 of the *Journal of the National Museum of Bloemfontein*. The first is by Dr. A. C. Hoffman and describes a dug-out canoe in use in Vendaland. It would seem to be the first of its kind to be found south of the Limpopo, and the first bark canoe to be described from southern Africa. The second article is by Dr. A. J. D. Meiring and describes some polished-edge bone implements found in the coastal strip from Great Brak River in the west to Matjes River in the east. The age may be Wilton.

The summer provincial meeting of the Physical Society will be held in the Department of Physics King's College, Newcastle upon Tyne 1, during July 13–14, the subject being optics and ultrasonics. The meeting will include visits to the Grubb–Parsons Optical Works and Pametrada Research Station. Hostel accommodation is available. The meeting is open to all on application to the offices of the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

The Present Question Conference this year will be on "Springs of Action" and will be held at Lady Margaret Hall, Oxford, during August 8–15. A number of lectures will be given in the mornings by leading experts, the subjects being tradition, the evidence of biology, politics, creative action, the longing for truth, knowledge, communication, moral judgment, productivity, leisure and personal decision. In the late afternoons and evenings, study groups and discussions will be held. The fee for the conference is 2 guineas (students 1 guinea). Accommodation is available in Lady Margaret Hall. Further information can be obtained from the Secretariat, Present Question Conference, 37 Middleway, London, N.W.11.

The second British Plastics Exhibition and Convention will be held at Olympia, London, during June 8–18. The Exhibition will cover a wide range from the raw material to consumer goods, and more than eighty firms and organizations will be represented. The Convention is designed this year especially for the plastics technologist, and a comprehensive programme of papers has been drawn up by representatives of the British Plastics Federation, the Plastics Institute, the Society of Chemical Industry (Plastics and Polymer Group) and the journal *British Plastics*. The Convention is open to all, admission being by ticket only, obtainable from the organizers, British Plastics, Dorset House, Stamford Street, London, S.E.1.

# NUMERICAL METHODS AND AUTOMATIC COMPUTING IN ATOMIC THEORY

A SYMPOSIUM on the application of automatic computing machines to the problems of extra-nuclear atomic theory was held in the University Mathematical Laboratory, Cambridge, on December 9 last. The subject was introduced by Prof. D. R. Hartree (Cavendish Laboratory, Cambridge), who began by pointing out that problems in this field are usually concerned with the solution of Schrödinger's equation, $H\Psi = E\Psi$, subject to appropriate boundary conditions. For many-electron systems it is necessary to resort to approximation in attempting to obtain solutions of this equation. Two important classes of problem are those of an electron in a bound state and in a free state: the former is characterized by $E$ being negative and assuming a discrete, unknown value corresponding to each bound state; in the latter problem, $E$ is positive and known for the phenomenon being studied, such as elastic or inelastic collision of an electron with an atomic system. Prof. Hartree continued with a more detailed account of the solution of the stationary-state equation for complex atoms along the lines of a previous paper of his (*Rep. Progr. Phys.*, 9; 1946–47). In particular, he outlined the defects of the Slater–Fock approximations in failing to express correlations between the positions of individual electrons in an atomic structure, and possible means of including, in the approximate wave-function adopted, terms expressing these correlations.

This introduction was followed by an account by A. S. Douglas (Mathematical Laboratory, Cambridge) of some recent work on improved approximations to stationary-state solutions using electronic computers. For the class of configurations consisting of a 'core' of closed shells of electrons and a single series electron, the Hartree–Slater–Fock approximation for the wave function of the series electron can be improved by including a polarization potential term in the equations. It is possible to determine by trial an empirical addition to the potential function in such a way as to bring the calculated energies of all terms of the optical spectrum into close agreement with the observed values; the agreement with experiment does not define the additional potential function uniquely. This has been done for $Si^{+3}$, using the EDSAC to compute the integrals involved in treating the additional potential as a first-order perturbation, and also to solve directly the equation, with exchange, including the additional contribution to the potential. The Runge–Kutta step-by-step method of integration developed by Gill for use on the EDSAC has been adapted for this purpose. An empirical rule for determining the additional potential for other structures has been postulated and is now being tested for $Ca^{+}$.

A second problem investigated by Mr. Douglas concerns the computation of an approximate wave-function for two-electron structures, such as helium, in the ground-state. Schrödinger's equation for helium can be reduced to a partial differential equation in three variables, and this can be solved approximately by solving a related parabolic equation involving an auxiliary independent variable $t$, the solution of which tends asymptotically to the required function as $t$ increases. The related equation can be replaced by its finite difference form and solved step by step in $t$. Exploratory work on the equation for the stationary states of hydrogen by this method indicates that a large number of steps in $t$ may be required, and has disclosed some anomalies in the process of convergence, which are under investigation.

In the afternoon, Dr. R. A. Buckingham (University College, London) gave an account of the use of variational methods of solving two-body and three-body collision problems. For slow electrons the only important contribution to the cross-section for elastic scattering is dependent on the asymptotic phase of the scattered electron. It can be shown that for small, restricted variations of the wave function, this phase is stationary, and this can be used for determining an approximation to the phase by one of the variational methods devised by Hulthén (1944) or Kohn (1948). These methods both involve solution of sets of simultaneous algebraic equations, those of Hulthén's method being quadratic, and those of Kohn's method being linear.

Even comparatively simple approximations to the wave functions for inelastic scattering lead to the necessity for solution of two simultaneous integro-differential equations. Such equations can be solved by the 'distorted wave' method used by Erskine and Massey (1952) in studying the inelastic scattering by hydrogen. Moiseiwitsch (1952) has shown that a variational method of solution is possible, and a finite difference method is at present under investigation. The application of electronic computers to the last two methods is likely to be of special value, in view of the very lengthy computations required. It is interesting that all these procedures have been successfully used in treating collisions between simple nuclei, such as the scattering of neutrons by protons, which have been studied by Swan (1952).

After a short discussion of Dr. Buckingham's paper, Dr. V. E. Price (Department of Theoretical Chemistry, Cambridge) described the use of the EDSAC to compute atomic wave-functions by the variational method due to S. F. Boys (1950–52). The required wave-function is considered expanded as a linear combination of 'serial products' of a complete set of chosen functions, the coefficients of the expansion being determined by use of the variational principle. For stationary-state solutions, the energy-levels are the eigenvalues of a matrix, the elements of which are found by evaluating certain integrals. Each one of these integrals contains not more than four members of the set of functions, and can be evaluated from a recurrence relation, provided a suitable set of functions is chosen. On the EDSAC such an evaluation takes about four seconds. To find the matrix elements from the integrals requires considerable algebraic manipulation, such as matrix multiplication, which can also be done on the machine. The eigenvalues of the resulting matrix, too, can be found by the machine. By taking a sufficiently large matrix, it is possible, in principle, to obtain any required accuracy for the solutions. This is not practicable, however, and it is necessary to choose the few particular members of the set of functions included in the calculation so that a good approximation is assured. A relatively simple calculation can be made to test the probable importance of omitted terms. Calculations on this principle have been carried out on a number of atoms and ions, including chlorine and sulphur, for which thirteen functions were used.

In the ensuing discussion, Dr. Boys (Cambridge) pointed out that the method used can be extended to find molecular wave-functions, the integral evaluation technique being largely applicable to this problem also. In reply to questions by Prof. Hartree and Dr. O. Bunemann (Cambridge), Dr. Boys said that the method is not likely to be of assistance in the nuclear field at present, since the accurate equations are not known with certainty. In answer to Dr. Buckingham, he said that electron affinities calculated by the method have so far shown disappointing lack of agreement with experiment.

After tea, two short contributions were given by visitors. Mr. W. A. Runciman (General Electric Co., Ltd., Wembley) described a problem connected with the fluorescence of a structure consisting of a potassium chloride lattice, in which some of the potassium ions are replaced by thallium. A first approximation to solution of this problem can be obtained by assuming the thallium ions to be in a free state, and an approximate evaluation of the wave functions by the self-consistent field method has been carried out on the EDSAC.

The final contributor was Dr. R. H. Garstang (University College, London), who mentioned a problem he had met in the analysis of departures from Russell–Saunders coupling; this involved the determination of the diagonal elements of a matrix, given its non-diagonal elements and its characteristic values.

A. S. DOUGLAS

# PHYSICAL FACTORS IN RELATION TO BIOLOGICAL ACTIVITY OF INSECTICIDES

A MEETING of the Crop Protection Panel of the Agriculture Group of the Society of Chemical Industry was held in the rooms of the Chemical Society in London on February 16, when papers on "Physical Factors in Relation to Biological Activity of Insecticides" were read. Dr. R. A. E. Galley was in the chair.

Mr. C. T. Lewis (Imperial College of Science and Technology, London) discussed factors affecting the adhesion of dry particles of uniform size to active insects. Experiments with selected dyestuffs have shown that dry lipoid-soluble particles adhere more readily to the cuticle of blowflies, and to leaf wax, than do lipoid-insoluble particles possessing polar groups. Presumably the presence of polar groups lessens the attraction at the solid–solid interface due to Van der Waals forces. The phenomenon has an appreciable influence on the rate of accumulation of particles by flies exposed to deposits. Parallel experiments with insecticidal dusts have yet to be performed; but significant effects may reasonably be expected since contact insecticides are lipoid-soluble and most diluent dusts are calcium or magnesium silicates.

Mr. Lewis also considered the effect of the 'cleaning' reactions of a treated fly on the retention and location of accumulated particles. Particles are picked up from a surface on ventral tarsal spines and chemoreceptors, and transferred in cleaning movements to less exposed parts of the body. The frequent cleaning movements result in a balance between the weights of particles at different locations, the head at all times retaining about 7 per cent of the total, the legs 48 per cent, the wings 13 per cent and the abdomen 28 per cent. The pulvilli are not important sites of accumulation, retaining about 2 per cent, and experiments have shown that they are not preferred sites of entry of DDT.

The rate at which fine particles are discarded by a contaminated fly depends largely on the rate at which the continued cleaning movements deliver particles back to the tarsal spines, from which they are returned to the substrate. The rate of loss is rapid until the quantity retained by the fly falls to 20 μgm., but is very slow below 10 μgm.

Dr. A. H. McIntosh (Rothamsted Experimental Station) dealt with the effect of certain conditions of test on the toxicity of a single insecticide, illustrated by reference to experiments in which insects were treated by dipping in aqueous suspensions of DDT. The weight retained depends upon the particle size, being greater for needle-shaped crystals than for colloidal particles. Temperature has a notable effect on toxicity, and the temperature coefficient, usually negative, varies with particle size and with humidity. High humidities accentuate the difference between the temperature coefficients of large and small particles.

The fact that poisons do not always have the same speed of action is an additional complication. The values obtained in relative toxicity tests may vary with the time at which observations of kill are made.

Dr. McIntosh also discussed the relation between the contact toxicity of insecticides and their fat-solubility. The first stage in the entry of a contact insecticide is assumed to be solution in the wax layer, and it is often implied that the higher the lipoid-solubility the more effective the poison is likely to be. An opposite conclusion can be deduced from Ferguson's principle of drug action, which indicates that different compounds have equal biological activity if applied at the same percentage saturation in the surrounding medium. Dr. McIntosh suggested that if this idea applied to the wax surrounding an insect, compounds of low fat-solubility should be the more effective. He pointed out, however, that there is no relation between the absolute toxicity of DDT and its analogues and lipoid-solubility. The view now held is that some degree of lipoid-solubility is necessary but it need not be high.

Experiments still in progress lead Dr. McIntosh to conclude that the difference in speed of action between colloid particles and crystals for a range of compounds of the DDT type may be related to the rate of solution of crystals in oil *in vitro*.

Dr. F. Barlow (Colonial Insecticide Research Unit, Porton) enumerated and discussed some factors of importance in the control of adult mosquitoes by residual spraying of houses. Mosquitoes are stimulated to flight after a short time in contact with insecticidal surfaces, and this fact increases the importance of physical factors affecting the availability of deposits.

The best formulation for deposits on absorbent walls is a wettable powder; the dispersing medium is absorbed, leaving insecticide particles freely exposed. On all types of surface, toxicity is inversely related to size of particle, because smaller particles are more easily picked up and retained by insects.

Dr. Barlow then dealt with factors affecting the persistence of deposits on various types of surface. Volatile insecticides exhibit decreasing residual action for a range of substrates from non-absorbent to absorbent. Increasing rates of evaporation and sorption into the substrate are responsible. Loss of insecticide has been found to be extremely rapid on certain adsorptive substrates and is due almost entirely to sorption; for example, on mud-blocks prepared from lateritic earths used for hut-building in several tropical countries.

Insecticides possessing fumigant action, for example, BHC and 'Aldrin', are effective for long periods after sorption, but others are ineffective after sorption, for example, DDT and 'Dieldrin'.

Finally, Dr. Barlow considered residual deposits of oil solutions. These deposits can be employed on non-absorbent surfaces, when formulations which do not crystallize are to be preferred because the recumbent crystals produced on such surfaces are not readily picked up by insects. By way of contrast, on fibrous absorbent surfaces, oil solutions are not available at first; but after crystallization has occurred the crystals project from the superficial fibres and are readily detached by insects.

Opening the discussion, Dr. A. B. P. Page observed that all three speakers had dealt with rate-determining processes. While there are big differences between fumigation and contact action, in each process accumulation and penetration of the toxicant are continuously occurring alongside toxification and detoxification within the insect. With fumigants, one measure of toxicity is the product of the concentration of the fumigant multiplied by the period of fumigation. In the same way the toxicity of a contact poison may be expected to be some integral function of the net amount of toxicant on the insect and the period of contact.

In certain fumigations a better measure of toxicity appears to be the amount of fumigant sorbed by the insects, and this relation implies dependence of toxicity on the shape of the concentration–time curve as well as on the area under it. An analogous relation may be found for contact poisons where large amounts of insecticide accumulated initially by the insect may greatly influence toxicity despite their rapid removal by cleaning movements.

Dr. Page remarked that Dr. McIntosh had concerned himself with the solubility of poisons in the epicuticular wax layer, but had not mentioned the possibility of preferred sites of diffusion through the cuticle and access to specific sites of action. Such considerations are important. Referring to Dr. Barlow's account of the fumigant action of certain solid insecticides absorbed into porous substrates, he recalled an analogous case of absorption in bagged stored products treated with an insecticidal dust; wheat, for example, can absorb enough DDT in the seed coats to enable the insecticide to act as a contact and stomach poison, whereas with BHC the fumigant action is all-important.

In reply to a question from Dr. J. R. Booer, Dr. McIntosh said that his colloidal suspensions were prepared in a standard way but he had not measured the size of particle.

Dr. J. C. McGowan pointed out that Ferguson's theory cannot be related to the system described by Dr. McIntosh. If insects are treated with aqueous solutions of insecticide, then the theory can be used; but the solubility of DDT in water is so low that a lethal dose cannot be applied by such a method. Mr. G. F. H. Whitney observed that Ferguson's theory applies to substances showing 'physical' toxicity; a substance showing a toxicity greater than that expected by the application of Ferguson's theory invokes 'chemical' toxicity. Dr. McIntosh commented that he had not stated that Ferguson's theory is valueless, but that it is not useful in the case of DDT and its analogues. In answer to Mr. P. S. Hewlett, he agreed that he considers the action of DDT to be physical.

Mr. F. H. Rae asked whether Dr. Barlow advocated whitewashing huts before spraying, which he considered would not be a practicable procedure. Was sodium silicate useful and could Dr. Barlow suggest any other substance which might reduce losses due to sorption? Dr. Barlow said that the ideal would be to incorporate a substance in the spray which would block the capillary spaces in the substrate and thus reduce sorption. Size is not suitable for tropical use. The problem is being studied; but he had no practical recommendations to make at present.

Mr. P. Bracey asked if it is known whether BHC in the vapour phase enters an insect through the integument or through the spiracles; Dr. Page thought that no information is available.

Closing the discussion, Mr. W. H. Read stressed the practical importance of work in this field.

# THE PLACE OF UNIVERSITY GRADUATES IN INDUSTRY

TWO most interesting points are featured in the report of the Universities and Industry Conference, organized by the Federation of British Industries and by the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom, and held at Ashorne Hill during October 24–26, 1952*: the first is the further support which is forthcoming for the argument advanced in the last report from the Advisory Council for Scientific Policy that a new attitude towards industry and technology is desirable on the part of the schools and the universities; and the second is the large measure of agreement in addresses and discussions to the effect that, in consequence of the large proportion of talent which is now entering the universities, industry must necessarily rely to a much greater extent on recruitment from the universities to provide its future leaders (its chances of recruiting the requisite ability from those leaving school direct has been greatly diminished). The published report contains the addresses by the following: Sir John Maud on the use of the university graduate in the Civil Service and the qualities of the graduate which have proved most useful; Sir Ewart Smith on the qualities industry requires in the university graduate and his role in industry; Dr. Eric Ashby on the ability of the universities, consistently with their other obligations, to turn out men with the qualities required by industry; and

---

* Report of the Universities and Industry Conference, organized by the Federation of British Industries and the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom, and held at Ashorne Hill, Leamington Spa, 24–26 October, 1952. Pp. 87. (London: F.B.I., 1953.) 5s.

Mr. A. D. Bonham-Carter, Mr. Ralph Colman and Mr. A. G. Grant on industry's use of the university graduate. Also included are Sir Robert Wood's reflexions on the conference at its final session, and a summary of the main points which emerged, by Sir Norman Kipping, Dr. C. R. Morris and Mr. D. R. O. Thomas.

Sir John Maud, in a very frank and stimulating address, made it clear that the Civil Service is looking for essentially the same qualities of integrity, courage, readiness to work, straight and original thinking and the capacity to make up one's mind as is sought by industry; nevertheless, he thought, while the Civil Service requires a larger proportion of first-class graduates than it has been receiving, it is of importance to the national interest that, during the next ten years at any rate, the claims of industry for first-rate men should receive priority. It is a matter of national importance that the university graduate should come to regard industry and commerce not merely as careers which offer a reasonable chance of a livelihood and of satisfying ambitions but also as opportunities of doing something in the nature of service in which they can take pride. Sir John earlier in his address had commented pointedly on some of the objectionable qualities to be found in the university graduate—qualities such as bad manners, inaudibility, and excessive specialization, which are not by any means limited to those who elect to enter the Civil Service.

Sir Ewart Smith likewise referred to the importance of influencing the general climate of opinion with regard to industry. He thought that wider recognition of the teaching of administrative studies in the universities would help to this end as well as to improve the quality of future management, but the idea that management should be taught in the universities found little support from him or other industrial representatives present, apart from Mr. N. G. McCulloch. The idea that management is a technology or a fit subject for university teaching was rejected forthright by Mr. A. G. Grant and Dr. Ashby, and Sir Ewart clearly voiced the general opinion of industrial representatives in his view that the first requirement is for men and women who have been trained to think, to understand, to be critical and to show initiative, and who have some understanding of wider aspects of life than can be gathered from one particular discipline. He thought that this wide outlook and capacity to think can be acquired through technology or science, as well as through the arts, if the subjects are properly taught, and at present, as Prof. J. A. L. Matheson reminded the Conference, the technological departments are not getting their fair share of first-class brains.

Dr. Ashby's address supplied the quantitative basis for the argument that industry must rely increasingly on the universities for its recruits for management. While, since 1912, the reservoir of persons eighteen years old has decreased by 74,000, the number from the reservoir who have entered universities has increased by 12,537, and during 1951 73 per cent of university students were receiving financial aid, mostly from public funds. The barrier to university education is now largely intellectual, not financial, and it is becoming difficult for a reasonably bright boy who remains at school to avoid going to a university. Already the universities are taking as much as a third or more of the educated high talent in the reservoir and may well take more as the machinery for separation becomes more efficient. This position makes it essential, continued Dr. Ashby, that the universities should discover the needs of industry; but he urged that industry should itself do much more to make known both its needs and its opportunities and to further a better understanding of the true purpose of industry, of its vital importance to the nation, and of the interest and satisfaction that it can offer to those who serve in its higher ranks.

That industry should do much more to explain its nature and purpose to the nation, and to persuade potential entrants that it provides a purposeful career with manifold opportunities for using good brains in essential work, was a main point which emerged at the Conference. This task should begin with the schools and the universities by publishing well-written literature designed to stimulate the imagination of young persons. The proportion of the ablest grammar-school boys who go to the universities has continued to increase, but the increase in the university population has not led to a corresponding increase in the number of men obtaining first-class honours degrees. Accordingly, even if industry were to recruit its due proportion of high ability of this kind, it might still fall short of its requirements, since the nation's total needs must be met from this strictly limited supply. This necessitates the fullest use being made of those with high ability wherever they are employed, and opinion was expressed that neither industry nor the Civil Service is yet making the best use of the specialist graduates it recruits.

Much remains to be done to broaden the education of the university graduate, and it is as clear from this conference as from the regional conference at Nottingham during the previous month that industry is critical of excessive specialization in first-degree courses and looks, above all, for those qualities on which Sir John Maud and Sir Ewart Smith laid emphasis. There is no evidence of a desire to stipulate a particular content of university education or, as already noted, to advocate the teaching of administrative studies at the undergraduate level. The universities would make their most effective contribution in the broader educational field by helping industry to continue the education and training of the graduates and men of equal ability it recruits. Reference was made to several experimental courses designed jointly by industry and the universities for men of this type who have been several years in industry and are twenty-five to thirty years of age. It was also noted that there has been no great industrial support for the postgraduate courses in technology which the universities have organized in response to a request made by industrialists at the conference held in 1949.

One further point needs to be emphasized by industry in its approach to the schools and universities regarding careers in industry. Although industry requires more men of high ability, the opportunities it can offer graduates are not unlimited. For most technical industries it is estimated that 4 per cent of the total employees fill scientific, administrative and management posts for which a graduate could appropriately compete. Only a few graduates could hope to reach the highest positions; but industry requires many more good men for the tasks of middle management, and these offer a full and interesting life. In this connexion the three papers on industry's use of the graduate led to a discussion in which Prof. A. R. J. P. Ubbelohde, supported by others, stressed the need for more quantitative information about industry's intake of arts or non-specialist graduates as compared with the intake of specialists of all kinds, the average industrial life of the graduate in any one firm, and the migration of specialists to non-specialist occupations in industry. Information of this kind would go far to assist in dealing with the problem presented by the arts graduate, particularly if, as suggested by Prof. H. S. Kirkcaldy, the arts graduate avoids specialization and acquires the ability to make intelligent use of experts.

## SARDINE FISHERY OF CALIFORNIA

THE fishery for sardines, *Sardinops cœrulea*, is a major industry in California; but there was a disastrous failure of the fishery during the 1947–48 season, and, although slight improvements have taken place in succeeding years, there seems at present little hope of a major recovery before the 1954–55 season at the very earliest. The area of profitable fishing has contracted to the region of southern California, resulting in extensive land transport of fish from there to the processing plants at Monterey and San Francisco.

As an emergency remedial measure the Sardine Industry Advisory Committee introduced a temporary programme of control and management for the 1948–49 season, but this proved unsuccessful and was dropped. Resulting largely from the undiminished initiative of the industry itself, a co-ordinated programme of sardine research by five scientific bodies has been brought into being. The agencies concerned are the California Academy of Sciences, the California Department of Fish and Game, the Stanford University (Hopkins) Marine Station, the United States Fish and Wildlife Service and the University of California (Scripps) Institute of Oceanography.

A progress report covering the period January 1, 1951–June 30, 1952, has recently been published[*]. The picture that emerges from the work to date is not encouraging. The fish population appears to be so reduced, and the possibility of significant recruitment of young fish so small, that unless the factor of availability operates to increase the normal catch of older fish, the sardine fishery must expect for at least another two seasons the smallest catches for a generation.

Data upon eggs and larvæ, young fish, food and feeding, growth- and mortality-rates, behaviour, schooling patterns and oceanographical conditions are being collected as rapidly as conditions allow—but long-term forecasting is not yet possible.

This important programme of co-ordinated research upon a vast and baffling problem is financed in part by funds from the industry in the form of a tax on landings, in part by a grant from the Federal Government and in part by a grant from the State of California, which makes the largest contribution.

The appearance of further reports on this very ambitious programme is awaited with keen interest, for it represents one of the most intensive combined assaults upon marine biological problems that has anywhere yet been made.

## OVERSEAS FOOD CORPORATION

### REPORT FOR THE YEAR 1951–52

THE annual report of the Overseas Food Corporation for the year ended March 31, 1952[*], differs in form from previous reports. Throughout the year the Corporation had been engaged in implementing the terms of the White Paper issued in January 1951, involving the running down of the vast organization built up for the mechanized production of groundnuts in East Africa, and also in an attempt to establish the economics of clearing and mechanized, or partly mechanized, agriculture under tropical conditions. The Corporation is thus now engaged in a large agricultural experiment, and, apart from the chapters on policy, organization and finance, respectively, the bulk of the report deals with the agricultural experiments in the three regions; the chapter on the work of the scientific department is likewise presented on a regional basis. The run-down in the Kongwa area is described in a separate report, appended to the main report, as are the accounts for the year.

The running-down operation has been effected with marked success and without serious detriment to the agricultural work. By March 31, 1952, the Corporation had handed over to the East African Stores Disposal Board about 80 per cent of its surplus stores and equipment, while transfer of the surplus fixed capital assets was virtually complete. The reduction of the European staff by 50 per cent to 636 and of the non-European staff by 18 per cent, giving a ratio of Europeans to non-Europeans of 1 : 23 in place of 1 : 14, proceeded smoothly, and a high proportion of Europeans leaving the service of the Corporation found satisfactory alternative posts in East and Central Africa. The London office has been reduced to a small agency, the Nairobi agency closed, and the Dar-es-Salaam agency incorporated with the general headquarters administration, which moved to Dar-es-Salaam during November 1951. Each region is now administered by a general manager, directly responsible to the chairman in his capacity as chief executive. With the exception of the chief health adviser, who was due to leave in July 1952, the technical advisers had already left the Corporation.

Decentralization of the engineering services is complete, and decentralization of the health department was to be completed when the chief health officer left in July 1952, by which date a reduction in European staff to 38 from the 85 at March 31, 1951, was envisaged. In this final report on health services the opinion is recorded that the danger to the health of Europeans in this area was much exaggerated, and the hospital bed planning figure, originally 2 per cent of the population entitled to treatment, has been reduced to 1 per cent and is being further reduced. The most effective measure for adult mosquito control has proved to be spraying all buildings with 'Gammexane' at three-monthly intervals, and this is now compulsory in Urambo and Nachingwea. Malaria is the commonest disease affecting Europeans, and, although 'Paludrine' has not been used either as a prophylactic or for treating Africans, there is evidence of the emergence of 'Paludrine'-resistant strains of the malaria parasite.

---

The run-down of Kongwa, which has now been divided into four separate farms with a total area under crop of about twelve thousand acres, presented special problems as this small area could not support economically the large installations built up to support both a large executive headquarters and three agricultural units each of thirty thousand acres. An administrator was appointed to run-down Kongwa and provide all the necessary services for the farms until they could be made self-sufficient. Kongwa has been declared a township by the Tanganyika Government, and on October 1, 1951, the Public Works Department assumed responsibility for the supply of water and electricity and the maintenance of roads. A small hospital has been retained and receives some contribution to its upkeep from the Tanganyika Government.

Although promising results have been obtained on the Kongwa farms since the Kongwa Working Party reported, experiments must continue for at least one or two seasons before conclusions can be drawn. Nevertheless, there are grounds for believing that a rotation in which groundnuts play an important part can be found. It is also evident that the estimated crop yields in both the Southern Province and in Urambo, especially in respect of the groundnuts, which is the main crop, cannot be obtained until much more is learned of the basic agricultural principles to be applied in these difficult areas. Groundnuts appear to be unlikely to play an important part in any rotation for these two areas, at least for several years to come, and accordingly the Board has recommended the slowing-down of the tempo of its operations in both these regions until the economics of the agricultural practices are fully established. Alternative cash crops, which have already stood the test of two seasons, are promising; and provided that due caution is exercised, it is anticipated that an agricultural pattern will be evolved and a mass of data accumulated which will make a real contribution to the development of these previously uninhabited areas in Africa.

In the Kongwa farms, yields per acre for the 1950–51 season averaged 367 lb. for groundnuts, 1,750 lb. for maize and 1,070 lb. for sorghum, and the experience gained during the season indicated that groundnuts should be given priority over maize in the planting programme. Although all seed was treated with 'Agrosan', collar rot (*Aspergillus niger*) caused considerable seed-bed losses in nuts during periods of dry weather and long periods of wet weather: in trial plantings 'Fernasan' seemed to give better control over collar rot. While trials with giant castor indicated that a fair yield can be expected in almost any season, there is room for considerable plant-breeding work for standardization in size of seed, time of maturing, etc., while it appears that hibiscus seed can be treated successfully to improve germination.

In the Urambo area yields per acre for the season averaged 404 lb. for groundnuts, 1,132 lb. for maize, 557 lb. for sorghum, 512 lb. for sunflower, 504 lb. for soya bean, 53 lb. for dwarf beans, 395 lb. for tobacco and 3,363 lb. for an experimental crop of rice grown by the scientific department. Sleeping sickness constitutes a constant threat, although no further cases were discovered, and the elimination and control of *Glossina morsitans* is a problem of the greatest importance, demanding much further research. A technical committee formed to deal with tsetse control in the area has recommended an approach to the Secretary of State for the Colonies, the East African High Commission and the Government of Tanganyika with the view of formulating and financing a research scheme.

In the Nachingwea area the average yields per acre of the two main crops were 756 lb. of groundnuts (in shell) and 1,053 lb. of maize; but the results from the cotton crop were unsatisfactory, due probably to late planting and the use of an unsuitable variety. Endeavours are being made to obtain varieties of soya beans suited to the local environment and fit for combine harvesting. Good yields were obtained from different varieties of millet, especially golden millet.

Soil fertility studies by the scientific department in the Kongwa region during 1950–51 were almost wholly concerned with the yellow sandy loams of the Mtanana series. Limestone in exploratory experiments with maize gave a mean increase of yield of 280 lb. per acre, and phosphate and lime applied together were the only first-year treatments which raised the yield of maize in the second year. Other experiments were carried out on soil of the Chamaye series to measure the effect of superphosphate, applied to four different crops in the first year, on the yield of groundnuts in the second year and to determine the residual value of eleven different phosphatic fertilizers. Experimental crop studies include trials of different varieties of groundnuts and of the effects of different dates of harvesting, as well as trials of dwarf and semi-dwarf sorghums, Kenya yellow maize, varieties of safflower and dwarf Hungarian castor. Many organic and metallic compounds were tested as seed dressings for groundnuts, and a detailed experiment showed that seed which has been damaged in the slightest degree may fail to germinate. Lesions of *Cercospora personata* were only found where the disease assumed serious proportions; but it is suspected that viable spores can persist in crop residues and in the ground, and a residue disposal trial was laid down. Infestation of sorghum by stem borers caused considerable losses, and *Calidu dregei* was also a major pest of sorghum.

In the Urambo region pronounced pedological changes have occurred during the past three years. Accumulation of rainwater in the soils through the complete removal of the natural vegetation has rendered a considerable proportion of the sandy soils unsuitable for mechanized production of arable crops, while there have been heavy losses in reserves of soil nitrogen through the rapid mineralization of organic residues from the woodlands by microbiological activity and subsequent intensive leachings by heavy rains. Soil fertility studies were confined to groundnuts, maize and tobacco. Early planting and the eradication of volunteer groundnuts in the dry season are at the moment the only means in the control of rosette of groundnuts. Stemborer may become a major pest of maize, and infestation of sorghum is also serious. A survey of three thousand acres of groundnuts in the Nachingwea region showed that an average of 3 per cent was rosetted, and a single spraying with 0·5 per cent of a systemic insecticide at 40 gallons per acre appreciably reduced the incidence of the disease. Much attention was given to a study of the biology of the insect vector of the disease. Trials of the effect of two seed dressings on groundnuts suggest that hand-picking of seed before treatment would improve the plant stand. Further evidence has been obtained that the soils in the Southern Province are, in general, deficient in phosphates.

# ANALYSIS OF ENVIRONMENTAL VARIABILITY IN QUANTITATIVE INHERITANCE

By E. C. R. REEVE and F. W. ROBERTSON

Institute of Animal Genetics, West Mains Road, Edinburgh

A LARGE fraction of the phenotypic variance of most quantitative characters is of environmental origin, even in populations maintained under carefully standardized conditions; but the nature of this non-genetic variability has received little attention, although it raises problems of fundamental importance in phenogenetics, particularly as the extent of variability may be very different for different genotypes[1]. The concentration of interest on genetic variations can be traced partly to the fact that statistical ideas borrowed from other fields have led geneticists to think of the environmental variance too much as an 'error variance'—a box into which all unexplained sources of variation can be conveniently dropped. The environmental variance is also difficult to study experimentally, since the factors responsible cannot usually be either controlled or measured, except when we are comparing two different environments. Some information can be gained about the nature of the variability within a single environment by examining the environmental correlations between different characters, and we shall illustrate this method of approach with two examples from *Drosophila melanogaster*, cultured under the conditions described previously[2], which appear to reduce non-genetic variability to a minimum.

Wing- and thorax-length both show a much lower variance in heterozygotes than in homozygotes[1], and we may ask how far this is due to differences in the effects of factors acting on both characters or on one alone. The common part of their variance may be taken as a measure of the variance of body-size, while the independent variations of each will be the result of errors of measurement, asymmetry of the two wings (one only is usually measured), and environmental factors acting on one character only. The problem can be given a simple statistical formulation, since both characters have about the same coefficient of variation in inbred lines, although the wings are twice as long as the thorax. We can therefore write (using percentage or logarithmic units) $w = c + i_w$ and $t = c + i_t$ for the two dimensions of any individual. $c$, $i_w$ and $i_t$ are uncorrelated variables measuring common ($c$) and independent ($i$) variations from the population means, and $i_w$ and $i_t$ have the same variance ($\sigma_i^2$). Then, for a population of given genotype:

$$\sigma_w^2 = \sigma_t^2 = \sigma_c^2 + \sigma_i^2 = \sigma^2 \text{ (say)}$$
$$\text{covariance } (wt) = \sigma_c^2.$$

In practice, $\sigma^2$ can be estimated as $\sigma_w\sigma_t$, so that the correlation between wing- and thorax-length is $\sigma_c^2/\sigma^2$, that is, the fraction of the variance due to common causes. This formulation allows us to compare the actual components of variance in inbred lines and their crosses. Table 1 gives the estimates obtained from two tests, the variances being expressed as squared coefficients of variation.

In both tests, the main cause of the reduced total variance in the crosses is the sharp drop in $\sigma_c^2$. The variance of body-size is actually more than twice as great in homozygotes as in heterozygotes, and the magnitude of the difference is under-estimated in comparisons using only one character, since there is a much smaller change in the independent variance ($\sigma_i^2$) than in $\sigma_c^2$. Errors of measurement have been found to cause only a small fraction of $\sigma_i^2$, so that environmental variables affecting only one character appear to differ less in their effects on homozygotes and heterozygotes than do those with general effects on body-size. As a result, the correlation between wing- and thorax-length is much less in the heterozygotes.

Table 1. COMPONENTS OF ENVIRONMENTAL VARIANCE IN INBRED LINES AND THEIR CROSSES (FEMALES)

| Comparison | | Nature of variance | | | Correlation coefficient |
|---|---|---|---|---|---|
| | | $\sigma_c^2$ | $\sigma_i^2$ | $\sigma^2$ | |
| *A* | Pure lines | 1·15 | 0·75 | 1·90 | 0·61 |
| | Crosses | 0·40 | 0·69 | 1·09 | 0·37 |
| *B* | Pure lines | 1·27 | 1·24 | 2·51 | 0·51 |
| | Crosses | 0·54 | 0·99 | 1·53 | 0·35 |

*A*, cross of two unselected lines; *B*, three crosses involving lines selected for small size

A different case is provided by the number of chætæ on the abdominal sternites of *Drosophila*, a character well known from the genetical work of Mather and his associates[3]. Males have three segments (No. 3–5) and females four segments (No. 3–6) with roughly equal numbers of sternal chætæ (typically about 20 and 25 in the two sexes). We thus have a serially repeated character in each individual, and it is of particular interest to examine the environmental correlations between the different segments.

One might expect both genetic and environmental effects to cause highly correlated variations of chæta-number on all sternites; and progeny tests on two wild stocks (to be described elsewhere) have shown that the genetical correlation between any pair of segments is close to unity. This means that gene differences mainly affect the general level of chæta production on all sternites and cause little or no local variations, so that one could expect little progress from selecting two segments in opposite directions. The environmental correlations have been estimated from nine inbred lines, each of which provides three correlations between pairs of segments in males and six in females, and the average correlations are given in Table 2.

Table 2. ENVIRONMENTAL CORRELATIONS FOR CHÆTA-NUMBER OF ABDOMINAL STERNITES

| | Adjacent segments | Non-adjacent segments | Average |
|---|---|---|---|
| Males | 0·075 | 0·087 | 0·079 ± 0·032 |
| Females | 0·050 | 0·063 | 0·056 ± 0·031 |

Adjacent segments are no more highly correlated than non-adjacent segments, and the average for all pairs of segments in both sexes is + 0·068 ± 0·022, a value in striking contrast to the high genetic correlations found (0·9–1·0). There is, in fact, virtually no non-genetic correlation, so that environmental variations must be extremely localized in effect. The non-genetic variability is, nevertheless, quite substantial, since the coefficient of variation for individual segments is about 8 per cent.

Another peculiarity of the variations of chæta is that the number of abdominal chætæ is extremely resistant to changes of environment, such as quality and quantity of food, humidity and temperature, which have profound effects on other quantitative characters[1,4]. It is, in fact, largely independent of external conditions. This has led to the suggestion that the variability is mainly due to "intangible accidents of development"[3]; but it may be argued that this does not really solve the problem, and the statistical facts need to be brought into relation with what is known about the morphogenesis of chætæ.

The relevant facts are as follows. A pair of small islets of embryonic cells, the hypodermal histoblasts, become visible four hours after formation of the puparium; they spread and form the ventral imaginal hypodermis of each abdominal segment during the next thirty hours. Towards the end of this period, the trichogen cells appear in the hypodermis, enlarge, and each gives rise to a chæta[4]. Each chæta is innervated by a bipolar nerve cell[5,6]. Various macrochætæ have a temperature-effective period in the late larva[7], and this has been taken to indicate that the trichogen cells are already in existence then, long before they can be seen[4]; but the temperature-effective periods for microchætæ do not appear to have been studied. What conclusions can we draw from these facts?

Since most of the external surface carries chætæ in more or less regular patterns, the tendency to produce them must be a general property of imaginal hypodermis; and, in view of the rapid development of the hypodermis from small groups of embryonic cells, it seems probable that the trichogen cells are induced shortly before they become visible, and do not exist earlier. It may be suggested that local irregularities in the newly formed hypodermis cause the induction of the trichogens and that some mechanism prevents them from forming too close together. This mechanism is almost certain to be connected with the rapid growth of the trichogen cells, which would exhaust certain materials in the immediate neighbourhood of each, and thus inhibit the formation of others near by. This leaves us with the problems of what could cause local irregularities in the hypodermis, and what could be responsible for the uncorrelated variations in numbers of chætæ.

Local irregularities could be caused by many factors, including the early presence of the nerve cells which later underlie the chætæ. But nothing is known of the history of these cells, and they may well be induced at the same time as the trichogens, or by them. It seems, in any event, far-fetched to attribute the regularity of the surface patterns to the regularity of underlying nerve cells. Any disturbance of the potential uniformity of the hypodermal tissue might be sufficient to set off the production of trichogen, and the regularity of the chætæ would then be maintained by the inhibitory mechanism postulated above. But we require some additional cause for the variability in number of chæta on each segment. The factors responsible cannot easily be equated with any known environmental variables, for the reasons given earlier, and must be very local in effect.

One agency which may contribute to this variation is somatic mutation. Genetic homogeneity of somatic tissue certainly cannot be assumed; and, since the hypodermis forming each abdominal sternite contains large numbers of cells, sufficient mutations might occur to affect the probability of production of chætæ at any point, and thus to vary the density of chætæ. Another possibility is that random disturbances acting on the newly formed hypodermis might destroy its homogeneity at a number of points, and so affect the siting of the chætæ. Thus, it has recently been suggested[8] that slight random disturbances could set off a chain of reactions in a homogeneous tissue leading to the production of a variable pattern, for example, dappling.

These suggestions are largely speculative, but may serve to encourage further study of the morphogenetic basis of production of chætæ. The facts put forward certainly reinforce our previous conclusion[2] that most of the non-genetic variation in number of abdominal chætæ, under normal culture conditions, is not an 'environmental' variability of the kind we meet in dealing with most quantitative characters. Such chance—or stochastic—variability may well be a property of many pattern characters. [Oct. 28.

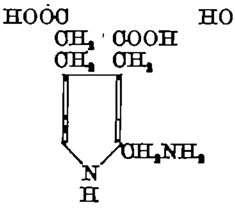
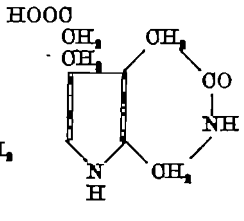
# PORPHOBILINOGEN

## Chemical Constitution

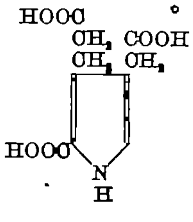
THE urine of patients suffering from acute porphyria contains a compound, porphobilinogen, which gives a positive Ehrlich reaction and which can be converted into a mixture of uroporphyrins on heating with acid[1]. Porphobilinogen was recently isolated in crystalline form by Westall[2], who kindly provided the material for this investigation. The reactions summarized below show that it probably has the structure (I). In an accompanying communication, Mrs. Kennard presents X-ray crystallographic evidence in support of a formula containing a single pyrrole ring.



(I)



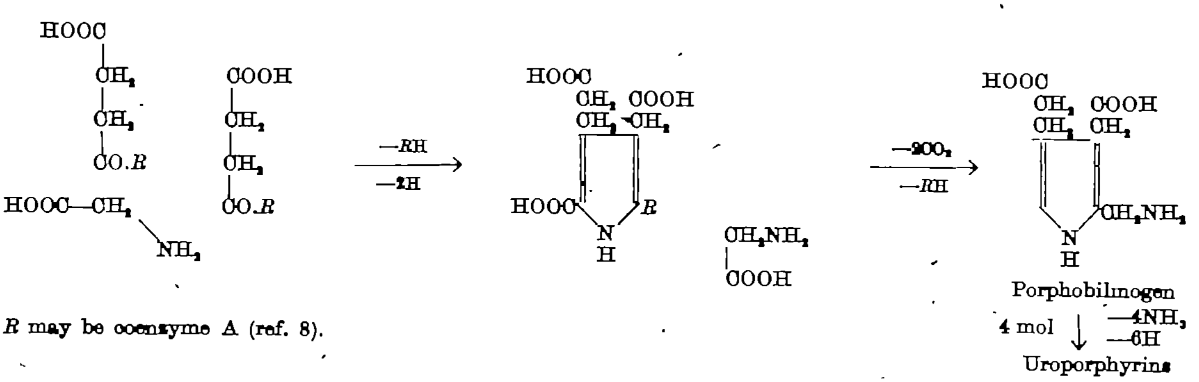
(II)



(III)

Porphobilinogen boiled with phosphate buffer ($p$H 8·5) loses ammonia but does not do so at 40° [3]. 2 : 4-Dinitroaniline has been isolated after treatment of a porphobilinogen solution at $p$H 8·5 and room temperature with 1 : 2 : 4-fluorodinitrobenzene.

When dissolved in strong alkali such as caustic soda or aqueous triethylamine, porphobilinogen gave, on treatment with acetic anhydride or benzoyl chloride, what were assumed to be the corresponding acyl derivatives; owing to their water solubility these could not be isolated. They were recognized on paper chromatograms run in butanol – 20 per cent acetic acid and developed with Ehrlich reagent (acetyl $R_F$ 0·79, benzoyl $R_F$ 0·92). However, when a solution of porphobilinogen in aqueous pyridine was treated with acylating agents, the major product was the lactam (II), which was unchanged by solution in caustic soda and further treatment with acetic



*R* may be coenzyme A (ref. 8).

anhydride. The lactam (II) ($R_F$ 0·65. Found: C, 57·6; H, 5·9; N, 12·9. $C_{10}H_{12}O_3N_2$ requires C, 57·7; H, 5·8; N, 13·45 per cent) with diazomethane gave its methyl ester, melting point 248–250° ($R_F$ 0·83. Found: C, 59·6; H, 6·6; N, 12·6. $C_{11}H_{14}O_3N_2$ requires C, 59·4; H, 6·3; N, 12·6 per cent). Both (II) and its ester showed a brilliant blue fluorescence under a Wood's lamp, but the only strong absorption in the ultra-violet was at *c*. 210 mμ, ε 7,500, as expected of a pyrrole with no conjugated chromophore[3].

The methyl ester of (II) underwent a Hoesch reaction with acetonitrile and hydrogen chloride to give its α-acetyl derivative. The product of the reaction, which was carried out on only 8·2 mgm., was investigated spectroscopically, the intermediate ketimine hydrochloride having $\lambda_{max.}$ 331 mμ and the acetyl derivative 306 mμ (cf. 2-acetyl-4-ethyl-3 : 5-dimethylpyrrole, 308 mμ[3]). 2·7 mgm. of the pure 2 : 4-dinitrophenylhydrazone were obtained (found: N, 19·2. $C_{19}H_{20}O_7N_6$ requires N, 18·9 per cent).

The infra-red spectra of porphobilinogen, the lactam (II) and its ester, which were kindly measured by Dr. L. A. Duncanson, of Imperial Chemical Industries Butterwick Research Laboratories, are in accordance with the structures assigned to them. The alternative structures with the positions of the β-substituents in (I) reversed, leading to a seven-membered lactam, have not yet been rigidly excluded.

The porphyrin formed when porphobilinogen was heated in acid solution yielded a crystalline octamethyl ester, melting point 255°. On paper chromatography[4] the major part of the material behaved as uroporphyrin III, but at least one other isomer was present. To explain the formation of a mixture of isomeric uroporphyrins *in vitro*, it has been suggested that porphobilinogen itself is a mixture[5]. We regard this as unlikely, X-ray (see accompanying communication) and chemical evidence being in favour of homogeneity. Other examples exist of the formation of mixtures of isomeric porphyrins from single compounds[6].

Isotopic tracer studies of hæm biosynthesis[7,8] have shown that natural porphyrins are synthesized from glycine and an unsymmetrical succinic acid derivative arising from the tricarboxylic acid cycle. Determination of the positions of the labelled atoms in the hæm led to the suggestion of (III) as an intermediate, which was then in some way converted to uroporphyrin, the methene bridges of which were derived from the α-carbon atom of glycine[9]. The structure of porphobilinogen which we now put forward can be immediately fitted into the scheme at the top of the page.

We are carrying out further work on this subject, and our results will be reported in full at a later date.

## X-Ray Crystallographic Determination of Molecular Weight

A PORPHYRIN precursor, porphobilinogen, was recently isolated by R. G. Westall in the form of the pure crystalline base[1] from the urine of patients suffering from acute porphyria. Chemical evidence by Westall[1] and by G. H. Cookson and C. Rimington (accompanying communication) suggests an empirical formula of $C_{10}H_{16}O_4N_2$ or $C_{10}H_{14}O_4N_2$ respectively. No molecular weight could, however, be assigned to porphobilinogen, and a crystallographic examination was undertaken to determine this and to differentiate between possible pyrrole or dipyrrylmethane structures, Waldenström and Vahlquist[2] having favoured the latter on the basis of diffusion experiments with porphobilinogen concentrates. In addition, it was hoped that the method would indicate whether or not two position isomers (*A* and *B*) were present. Intermediates of this type with unspecified α-substituents were postulated by Neuberger, Muir and Gray[3] in their theory of the biosynthesis of porphyrins.

Crystallographic methods were recently used to differentiate in a similar way between the various porphyrin isomers[4].

COMPARISON OF UNIT CELL DIMENSIONS

| Substance | *a* | *b* | *c* | α | β | γ | No. of molecules | Space group |
|---|---|---|---|---|---|---|---|---|
| Porphobilinogen HCl $H_2O$* | 13·9 A. | 17·9 A. | 5·34 A. | 97° | 97° | 89° | 4 | *B*1 or *B*$\bar{1}$ |
| α-Porphobilinogen HBr $H_2O$* | 14·0 | 18·0 | 5·34 | 97° | 97° | 89° | 4 | *B*1 or *B*$\bar{1}$ |
| β-Porphobilinogen HBr | 15·7 | 15·4 | 5·23 | 90° | 96° | 90° | 4 | $P2_1/n$ |
| Coproporphyrin I tetramethyl ester | 11·1 | 17·4 | 5·50 | 93° | 96° 40′ | 123° | 1 | *P*1 or *P*$\bar{1}$ |

* Referred to a *B* face-centred cell twice the volume of the primitive cell

*Porphobilinogen hydrochloride*. The free base was converted into the hydrochloride by treatment on a silicone-coated slide with cold 2*N* hydrochloric acid. The fine needle-shaped crystals appeared optically homogeneous. Centrifuged in a Linderström-Lang type density column[3] the crystals formed one sharp band at a density-level of 1·405 gm./c.c. The X-ray diffraction pattern of a number of separate crystals was identical.

Porphobilinogen hydrochloride was found to be triclinic. Cell dimensions, calculated from rotation and Weissenberg photographs, were $a = 7{\cdot}5$ A., $b = 17{\cdot}9$ A., $c = 5{\cdot}34$ A.; $\alpha = 96^\circ\,17'$, $\beta = 117^\circ\,8'$, $\gamma = 87^\circ\,27'$. Mass per unit cell (O = 16) calculated from the above data is 553·3 ± 25. Analytical values agree with the formula for the monohalide with one molecule of water; molecular weight calculated for two units of $(C_{10}H_{14}N_2O_4HCl,H_2O)$ is 561. Piezo-electric tests, as well as the Wilson statistical tests[6], failed to decide the presence or absence of a centre of symmetry. Accordingly the unit cell may contain one molecule of dipyrrylmethane, or two molecules of monopyrroles which may or may not be position isomers.

*Porphobilinogen hydrobromide*. When converted to the hydrobromide, porphobilinogen crystallized in two forms, the α-form, isomorphous with hydrochloride, and β, a monoclinic form, prismatic in appearance (see photograph). The two forms occurred together, in variable proportions, and attempts to produce one form alone were unsuccessful. To obtain fractionation, use was made of the difference in the specific gravity of the two forms, and complete separation achieved by centrifuging the material in a density column of suitable gradient.

Porphobilinogen hydrobromide, showing the long needle-shaped crystals of the α (hydrated) form and the prismatic habit of the β (anhydrous) form. Magnification × 80

The unit cell dimensions of the α-form were found to be: $a = 7{\cdot}5$ A., $b = 18{\cdot}0$ A., $c = 5{\cdot}34$ A.; $\alpha = 96^\circ\,14'$, $\beta = 114^\circ\,8'$, $\gamma = 87^\circ\,24'$. Observed density 1·587 gm./c.c. The total molecular mass (O = 16) calculated from X-ray data is 628 ± 25. The molecular weight calculated for $(C_{10}H_{14}N_2O_4HBr,H_2O)_2$ suggested by the analytical data is 649·8. Again no distinction could be made between space groups *P*1 and *P*$\bar{1}$.

The β-form has been examined chromatographically by Cookson and Rimington and found to be homogeneous and convertible to an octa-carboxyl porphyrin. It crystallized in space group $P2_1/n$. Absent reflexions: ($h0l$) if ($h + l$) is odd; $0k0$ if $k$ is odd. Cell dimensions are shown in the accompanying table. Density, 1·595 gm./c.c. The mass per unit cell (O = 16) is 1,211 ± 50, which agrees within experimental error with the presence of four formula units of $(C_{10}H_{14}N_2O_4HBr)$, $M_{\text{calc.}}$ being 1,227·6. Symmetry considerations require that the unit cell contains either groups of four identical molecules in general positions or groups of two identical centrosymmetrical molecules in special positions. Since the proposed dipyrrylmethane molecule is extremely unlikely to have a centre of symmetry, crystallographic evidence would favour the monopyrrole structure for porphobilinogen, and shows that an octa-carboxyl porphyrin can be produced from a compound containing molecules of one type of isomer only.

The mean molecular weight for the free base calculated from the three types of crystals examined is 221; molecular weight calculated for $(C_{10}H_{14}N_2O_4)$ = 226.

*Coproporphyrin I tetramethyl ester*. The unit cell dimensions of this substance have been determined and are included in the table. Similar measurements of a uroporphyrin could not be carried out for lack of suitable single crystals. Coproporphyrin I ester provides an interesting comparison with porphobilinogen as the unit cell contains one molecule, the equivalent of four pyrrole units only in a space group of *P*1 or *P*$\bar{1}$. The distribution of intensities in the X-ray diffraction pattern indicates that the molecule is not strictly centrosymmetrical and favours a space group of *P*1. The similarity between the unit cell dimensions of the porphobilinogen halides and this porphyrin ester suggests a common structure-type and lends indirect evidence for the proposed molecular structure of porphobilinogen.

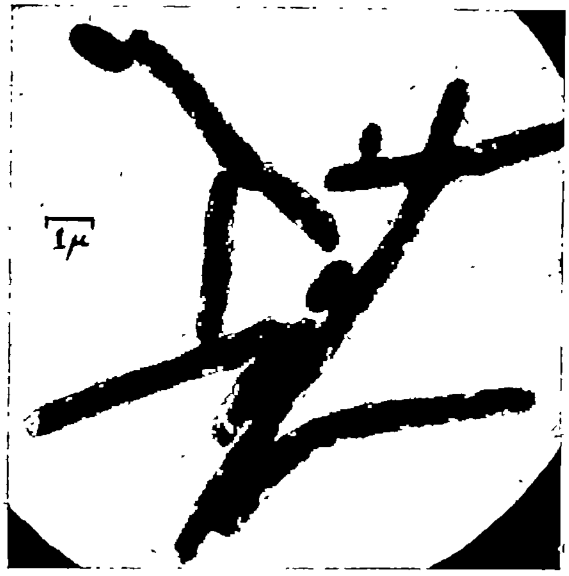
## A New Procedure for Bacterial Viability Counts and its Biophysical Applications

A BASIC problem in microbiology is that of determining the proportions of live and dead organisms in a bacterial culture. The standard procedure is to spread a known volume of diluted culture over a solid nutrient-medium and then, after incubation, to count the colonies which develop. On the assumption that each colony came from one bacterium, the number of viable organisms per millilitre of original culture can be calculated (but not the percentage viability).

We have found useful a completely different method which consists simply of counting in an electron microscope the live and dead organisms in a random sample of any culture. Live and dead bacteria cannot normally be distinguished from each other. However, if the culture is incubated for a few hours under conditions which permit cell-growth but inhibit cell-division, the live organisms will grow to many times the length of their dead companions and the two kinds can readily be differentiated and counted (see photomicrograph).

A convenient agent for inhibiting division but permitting growth is urea at a concentration of 3 per cent in nutrient agar[1]. The bacteria are grown on a collodion film supported on a stainless-steel electron-microscope specimen grid in a manner similar to that described by Brieger and Cosslett[2]. The grids are placed film downwards on a Petri dish of nutrient agar containing 3 per cent urea. A drop of bacterial culture is then placed on the centre of each grid and the whole incubated at 37° C. for 3 hr. (6 hr. for irradiated bacteria, to allow for the longer lag phase). The grids are then fixed in vapours of osmium tetroxide or formalin, cleaned by floating on distilled water, and finally dried and examined. The live bacteria in the drop will have formed long filaments, whereas the dead ones remain unchanged. Provided the distribution of bacteria on the grid is suitable, a count of the live and dead cells can then be made. Test-counts on suspensions containing known proportions of live and heat-killed bacteria gave answers correct to within the expected sampling error, which is small if several hundred cells are counted. Examination in an electron microscope is probably essential for making accurate counts—especially for distinguishing very short rods from particles of medium or detritus, and for including lysed cells.



A typical field of paracolon bacilli after 2½ hr. growth at 37° C. on division-inhibiting medium (3 per cent urea-agar), showing seven live and three dead organisms.

The 'urea method' is often less time-consuming and troublesome than the standard method. Its main disadvantage is that it cannot be applied to cocci, which do not respond to urea by developing into giant forms, or to cultures of organisms which always contain filamentous cells in spite of being cultured under conditions favouring short forms. But we have used it successfully with strains of *Bacterium*, a paracolon bacillus, *Chromobacterium*, and *Pseudomonas*. With suitable strains, counting by the urea method has several important advantages over the standard procedure: (*a*) it is not affected by bacterial clumping, which can entirely vitiate the standard procedure[3]; (*b*) it gives percentage viability, instead of only a total live count per unit volume; (*c*) the dead cells can be identified and examined; (*d*) only a very small sample is required.

The method has proved very useful in studying the resistance of bacteria to drying in fine droplets (as happens so often in Nature), and has also thrown new light on the effects of radiations on bacterial cells. In the latter case the counts may differ widely from those made by the standard procedure, since the urea method measures primarily radiation effects on the systems responsible for cell growth. It presumably does not detect effects on the systems responsible for cell division and heredity, which do, however, affect counts made by the standard procedure. Clearly, in most experiments on bacterial killing, fuller information can be obtained by using the two methods in parallel.

Further details of this and other work based on the urea method will be published elsewhere. One of us (R. C. V.) is indebted to the Agricultural Research Council for support during this work.

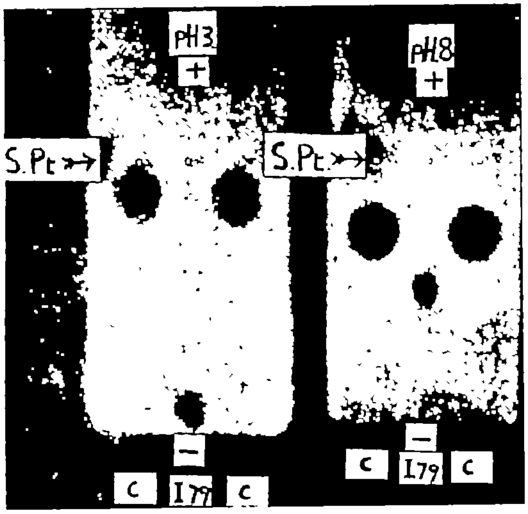
## Applications of Electrophoresis in studying New Antibiotics

THE application of paper electrophoresis to the study of new antibiotics[1] has been in use at these laboratories for some time. Our technique consists of applying spots of culture fluid, or a concentrate of it, to paper strips soaked in buffer, and subjecting the strips to electrophoresis by the technique of Kunkel and Tiselius[2]. Spots of chloromycetin are applied to the paper on each side of the spot of unknown antibiotic as a control for electro-osmosis. After migration, the position of the antibiotic is revealed by the microbiological technique as usual



Electrophoresis of antibiotic 179 relative to chloromycetin (C). S.Pt., starting point

in paper chromatography of antibiotics[3]. Thus it is possible to determine whether unknown antibiotics in culture fluids are acidic, basic or amphoteric, and to obtain an approximate measure of their isoelectric point as a guide to subsequent purification procedures. The migration of an unknown antibiotic 179, relative to chloromycetin, to the cathode at *p*H 3 and *p*H 8, with lessened mobility at *p*H 8, indicates a basic substance with an isoelectric point greater than *p*H 8, as illustrated in the accompanying photograph.

During the course of our studies, a number of apparently anomalous results were observed which proved to be the result of one or more of the following effects: (*a*) movement of spots during the drying process; (*b*) uneven distribution of electrolytes on the paper; (*c*) adsorption of the antibiotic by the paper.

*Movement of spots during drying of the paper.* When filter papers were dried at the conclusion of electrophoresis, definite movements of spots of dye (bromphenol blue) were shown to occur due to the flow of water during evaporation. The extent and direction of the movement varied surprisingly with the conditions of drying and the relative positions of the spots on the paper. Such movements and the contraction of the whole paper on drying are factors which limit the possible agreement between measurements made by paper and classical electrophoresis.

*Uneven distribution of electrolytes.* By incorporating an indicator in the buffer used for electrophoresis, it was shown that electrolytes added along with the substance under examination may separate during electrophoresis into discrete acid and alkaline areas which disperse only slowly. Considerations were, therefore, given to the choice of buffer concentration on the paper and the concentration of electrolytes in the sample submitted for electrophoresis. This observation stresses the need for considering the entire electrolyte concentration of a solution on which paper electrophoresis is contemplated.

*Adsorption of the antibiotic by the paper.* The chromatographic development on filter paper of a number of known and unknown antibiotics with buffers demonstrated a property in common, of strong adsorption at *p*H 8 and less so at *p*H 3, while chloromycetin showed little adsorption. With a knowledge of the relative adsorptions of an unknown antibiotic and chloromycetin, it was possible to interpret electrophoretic movements of the former even when strong adsorption on the paper occurred.

*Choice of a suitable control for electrophoresis.* Chloromycetin is a suitable control because it is little adsorbed, is indicated by the same methods as the antibiotic being studied, and shows electrophoretic movement on filter paper close to that of dextran, already established by Kunkel and Tiselius[2] as a suitable control for electro-osmosis.

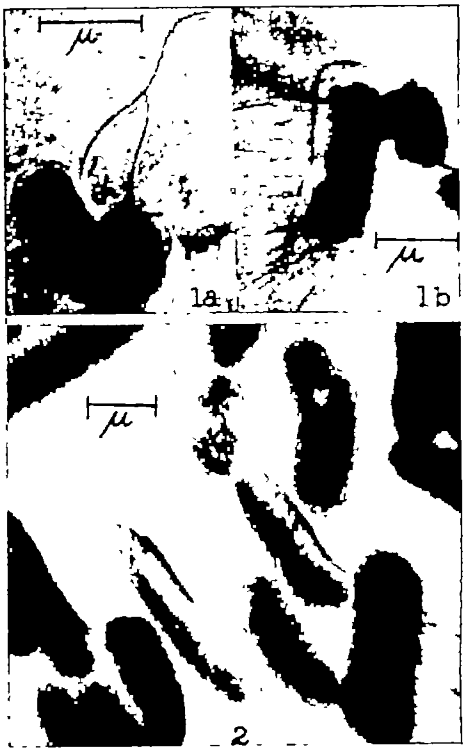
## A Variant of *Bacterium coli*

During an electron microscopic investigation of *Bacterium coli*, a variant form of this bacterium was observed with several interesting features. The accompanying electron micrographs 1(*a*) and 1(*b*) show the normal types of this bacterium usually obtained. In both cases bacteria were grown on



Electron micrographs of *B. coli* shadowed with 80 A. of chromium metal. 1(*a*) normal type fixed in 2 per cent osmic acid vapour (× 13,600); 1(*b*) normal type fixed in 5 per cent formalin (× 11,200). (2) Variant fixed in 2 per cent osmic acid vapour (× 8,800)

Morton–Engley's enriched agar medium[1] and incubated for $2\frac{1}{2}$ hr. at 37° C. Bacteria represented in Fig. 1(*a*) were fixed by exposure to vapour of 2 per cent osmic acid, whereas those of Fig. 1(*b*) were fixed in 5 per cent formalin. Those fixed in formalin always showed a greater shrinkage of protoplasm from the cell wall, compared to those fixed in osmic acid vapour.

In the normal type of this bacterium, the surface of the body is smooth; two types of flagella are usually observed, the long and thick variety (Fig. 1(*a*) ) which are few in number, and the narrow filamentous type (Fig. 1(*b*) ), which are more profuse and peritrichous in distribution. The flagella originate from the lateral surface of the body and extend right up to the cytoplasm, as may be seen through the collapsed cell membrane in Fig. 1(*b*). Except when the cytoplasm has shrunk considerably, the body of the bacterium shows unequal transmission of electrons, possibly corresponding to the nuclear and cytoplasmic regions[2].

In the variant form (Fig. 2), the body appears hairy, and in a few cases long hairy outgrowths are twisted together and resemble a twine. The hairs seem to be of surface growth and no normal flagella are seen. The bacteria are in general more transparent to the electron beam than the normal forms. Variants of *B. coli* have been observed before by different authors[3-5]. Vaureka[3] observed a hairy variant of *B. coli* under the phase-contrast microscope, when bacteria were treated with chloramphenicol and antiserum. In this case a hairy lining membrane appeared just before the death of the cell. Eisenstark *et al.*[4] observed a mottled variety of *B. coli* after treatment with X-rays. In our case, the hairy variety was found to occur spontaneously in the normal culture, and it maintained this characteristic through several subcultures.

We wish to thank Prof. M. N. Saha for his interest in this work. We are also indebted to the Ministry of Education, Government of India, for financial assistance.

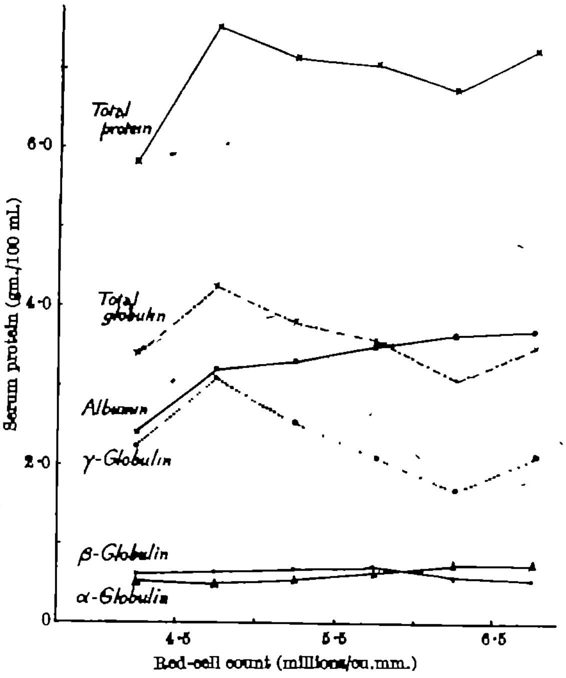
## Serum Proteins in Africans

It has frequently been observed[1] that the serum globulin-level of apparently normal Africans is higher, and the albumin-level somewhat lower, than that of Europeans. Moreover, workers in this laboratory[2] have shown that there is a relation between mean red-cell count and serum protein-levels. Those Africans with the highest red-cell counts have a higher mean albumin-level and a lower globulin-level than those with lower red-cell counts. In this work, chemical methods[3,4] for separating and estimating the serum protein fractions were used. By these methods it appeared that the variation of the β-globulin fraction accounted for the greater part of the change in total globulin in the different red-cell-count groups.

This work has now been repeated, and in the main confirmed, using a micro-electrophoresis (Antweiler) method for estimating the serum protein fractions. The proteins were measured in the ascending limb in barbitone buffer of $pH$ 8·6, ionic strength 0·12. By this method serum protein-levels of normal Europeans living in Africa were found to be close to those given in the literature for normal subjects; and the means for a group of seven African medical students were similar to those of the Europeans except for the γ-globulin-level, which was more than twice the European mean.

Blood samples were taken from fifty-five surgical out-patients who reported for minor or constitutional surgical conditions which could not *primâ facie* affect the serum proteins, or who required a physical examination for a health certificate. Serum protein measurements and red-cell counts were made on each sample. The figures for protein concentration were arranged in groups according to the red-cell count, and the means for each group were calculated. The results are shown in the accompanying graph. It is seen that there is a progressive increase of mean serum albumin from the lowest blood-count group (less than 4·5 million) to the highest (greater than 6·5 million). In contrast with our earlier findings, the mean α- and β-globulin-levels show little variation in the different blood-count groups, the variation of globulin occurring almost entirely in the γ-globulin fraction.

This discrepancy with the previous work is due to the fact that, in African sera, a proportion of the substances having the electrophoretic mobility of γ-globulins is not precipitated by saline ammonium sulphate, as used in the method[5] employed in our earlier work. Whereas in European sera which we have examined the figures for γ-globulin obtained by electrophoretic and chemical methods agree well, in African sera the chemical figure is always lower than the electrophoretic figure. By the method of Wolfson *et al.*, the β-globulin concentration is found



by difference, that is, the values for (albumin + α- + γ-globulin) are subtracted from the total protein; and if by this method the γ-globulin is under-estimated, falsely high figures for β-globulin must be obtained. It appears from our later experiments that the variation in the different blood-count groups occurs mainly in that part of the γ-globulin which fails to be precipitated by saline ammonium sulphate.

The significance of the raised γ-globulin concentrations of African sera is now being investigated.

I am indebted to Mr. John Kyobe for red-cell counts made in connexion with this work, and to Mr. John Croot for access to the subjects.

# Inhibitory Effect of Malonate on the Respiration of Brain Tissue, with Special Reference to the Potassium Effect

IT has long been known that, in brain cortex slices, both aerobic glycolysis and respiration are enhanced markedly when potassium chloride (0·1 *M*) is added to the suspension medium[1], this metabolic effect of potassium being peculiar to nervous tissue[2] and abolished by grinding the material[3]. In view of the manner in which the increased aerobic glycolysis and respiration respond to various metabolic poisons such as potassium cyanide, malonate and mono-iodoacetate, it seems possible that the type of linkage of these two metabolic routes differs from that under normal conditions[4].

Although Dixon[5] and Dickens and Greville[6] have put forward a hypothesis to explain the underlying mechanism of the effect of potassium in terms of permeability, its nature is still obscure[4], if somewhat clarified by the recent work of Lipsett and Crescitelli[6]. In the present communication we wish to direct attention to the effect of malonate on the increased respiration caused by the addition of potassium.

Fig. 1 shows that the respiration in presence of potassium chloride is strikingly inhibited by the addition of malonate ($10^{-3}$ *M*), being depressed nearly to the level of the normal respiration, which is itself maintained steadily even in the presence of malonate[7]. If the concentration of malonate is increased to $10^{-2}$ *M*, respiration in presence of potassium chloride is completely inhibited, even to the level of the endogenous respiration of the brain tissue without added substrate, as seen from Fig. 2 (*a*) and (*b*). Again, the respiration in the normal saline medium remains substantially resistant to malonate, whether glucose is present or absent. Thus the respiration in presence of excess potassium is acutely susceptible to malonate as contrasted with the normal respiration, which is quite resistant to the same poison.

In view of these facts, bearing in mind that malonate tends to promote the increased aerobic glycolysis due to potassium and further that the potassium effect is reversible, the possibility suggests itself that in potassium chloride – saline, either the Krebs cycle is the main pathway of brain tissue respiration, or the Krebs cycle, which is masked in some way or other under normal conditions, is opened up and brought into operation by the addition of excess potassium. Even though the mode of action of potassium on these metabolic processes is at present still a matter of conjecture, it must be significant

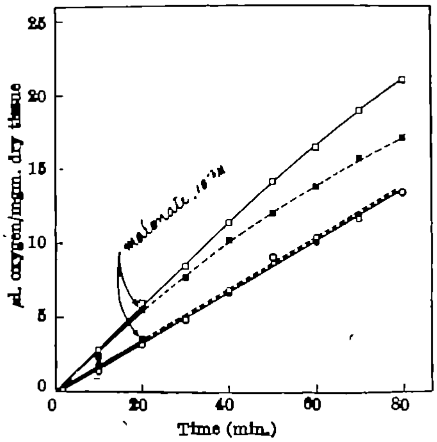

Fig. 1

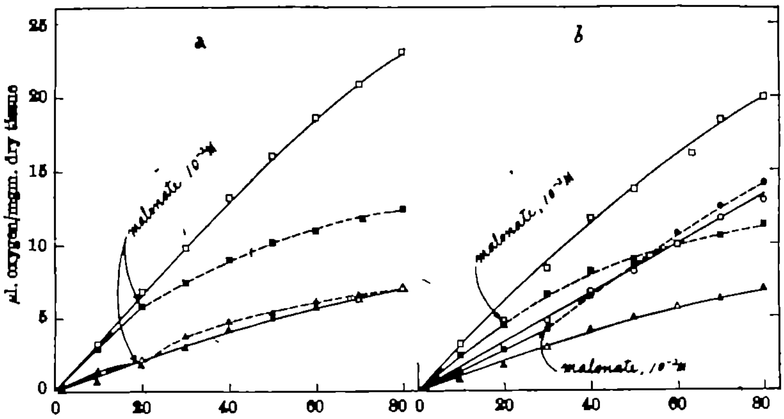

Fig. 2

Fig. 1 and Fig. 2 (*a*) and (*b*). Effects of malonate on the respiration of brain cortex slices of guinea pigs in presence and absence of excess potassium chloride; suspension medium, Krebs–Ringer phosphate solution.

## Nerve Fibres in the Adrenal Cortex of the Rat

IT is generally accepted that the adrenal medulla receives a predominantly pre-ganglionic nerve supply, reaching it via the great and lesser splanchnic nerves and by branches from the lumbar sympathetic chain[1-3]. Such fibres traverse the cortex in compact bundles (Fig. 1), without branching or relaying in the cortex, and are easily demonstrable by silver impregnation methods, as is the medullary nerve plexus which they join.

On the subject of an intrinsic nerve supply to the adrenal cortex, opinions differ widely. Thus Stöhr[4] believed the cortex to be richly innervated, whereas earlier, Hoshi[5] had stated that it possessed no nerve supply. Hollinshead[1] found no clear-cut example of a cortical innervation following silver impregnation; he did, however, describe single fibres and small groups of fibres distributed with the cortical blood-vessels and losing themselves upon these vessel walls. He assumed that these nerve fibres were postganglionic on the grounds that they persisted after section of selected ventral nerve roots. More recently, Kiss[3], using a silver impregnation method, has claimed that the outer cell layers of the cortex are innervated by collaterals from a rich subcapsular nerve plexus. This innervation, he states, comprises both postganglionic sympathetic and sensory fibres, and joins the "grundplexus" of Boeke[6]. He claimed, moreover, to have demonstrated occasional button-shaped nerve endings in relation to the cortical cells. Protagonists of a cortical innervation have not supported their work with photographs.

In recent work, adult male albino rats were injected intravitally with a 0·5 per cent solution of methylene blue in 0·3 per cent aqueous sodium citrate[7]. Using a transfusion apparatus and a broad-bore intravenous needle, the femoral vein was cannulated and a dose of about 40 mgm. of methylene blue was usually given before death ensued after twenty minutes. The glands were fixed in 8 per cent ammonium molybdate at 0° C. overnight, then washed in ice-cold saline, rapidly dehydrated, cleared and finally embedded in paraffin. Sections ranging from 6 to 20 μ thick were mounted in balsam.

Structures very suggestive of nerve fibres and nerve endings were observed in the outer layers of the cortex (Fig. 2). They were stained a deep purple colour, in contrast to the pale blue of the connective tissue. Two varieties of these fibres were present: (*a*) a fine plexus running with the cortical arteries (Fig. 2), with a possible extension over capillary walls; (*b*) branching systems of fine and frequently beaded fibres with occasional button-shaped endings in close relation with cortical cells. In Fig. 2 this relationship can be appreciated, since some of the cell nuclei have been stained by the dye. Both types of fibre distribution appeared to be derived from a subcapsular plexus in which small darkly stained ganglion cells could be occasionally discerned. The first type of nerve distribution, that is, along vessel walls, although most frequently seen in the subcapsular region, zona glomerulosa and zona intermedia, could often be found in the zona fasciculata, but not deeper in the

gland. The second type of distribution, as judged by recognizable buttons in relation to cells, was apparently confined to the zonæ glomerulosa and intermedia and the outermost zona fasciculata.

In order to follow up these findings, two silver impregnation techniques were used[8,9] for demonstrating reticulum (Fig. 4) and nerve fibres (Figs. 1, 3 and 5). While no absolutely convincing nerve endings were seen by silver impregnation, yet some of the appearances were very much akin to the buttons made visible by methylene blue preparations. However, fine nerve fibres were often seen, both as a network around small arteries (Fig. 3) and singly (Fig. 5) or in groups, in relation to the cells of the zonæ glomerulosa, intermedia and outermost fasciculata. All these fibres were much finer than the obviously myelinated fibres to the medulla which transverse the cortex in bundles (Fig. 1), and also finer than the strands of reticulum (Fig. 4).

These findings suggest therefore that, in addition to a possible vasomotor innervation, the adrenal cortex may possess a nerve supply to its outer cell layers. It would also seem that intravital injections of methylene blue provide a useful means of studying these nerves. Further work on this problem is being attempted.

## A Possible New Principle in Taxonomy, and its Evolutionary Implications

In the course of studies on the taxonomy of Coleoptera, lasting many years and dealing with groups at all levels from sub-orders down to species, it has gradually been borne upon me that taxonomic groups are not usually to be distinguished from the nearest related ones by more than one really-constant character. Expressing the same concept in another form, if a taxonomic group is distinguished from related ones by the possession of character *A*, its constitution will not be quite the same as it would be if it were defined by the possession of character *B*. From superficial observation, the same principle appears to hold very generally in the animal kingdom, and quite probably among plants as well. Though this circumstance may well be familiar to many taxonomists, it does not appear to have been explicitly recognized as a general principle hitherto; if it is ultimately considered worthy of a name, I suggest 'the non-congruence principle'.

The implication of the non-congruence principle seems to be that differences of the sort used by taxonomists normally evolve one at a time. If any general statement can be made about taxonomic characters, it is probably that they exhibit more-or-less marked discontinuities but do not segregate like single gene mutants. The discontinuities are therefore presumably adaptive rather than genetical in origin, that is, they result from the relative inadaptiveness of the intermediate conditions; the evolutionary changes producing the differences were presumably relatively rapid. Genetical analysis of segregation in interspecific and intergeneric hybrids suggests that such differences involve changes in numerous genes.

To a non-specialist geneticist like myself, it seems quite plausible to assume that, if an adaptive change 'gets under way' involving a co-ordinated shift in a large number of separate hereditary factors, the genetical machinery of a species is liable to become 'tied up' in a way which would render it difficult or impossible for another change of the same type to be carried out simultaneously. If so, an explanation is provided for the apparent inability of selection to operate on more than one taxonomic character at a time, and the non-congruence principle would follow as a necessary consequence.

To take a familiar zoological instance of the possible application of the principle, we may consider some of the characters of the class Mammalia. The characteristic dentition, the secondary palate, the lower jaw suspension, the fur-clad skin, viviparity—in distinguishing Mammalia from Reptilia these characters are almost equivalent; but not quite, for the criterion of viviparity would exclude the Monotremata from the mammals, while the dentition alone would include a large number of Theromorph reptiles, and the secondary palate would include some of the later Theromorpha. According to D. M. S. Watson, there is some reason for supposing that the hairy skin first appeared with the small Ictidosauria (for example, *Oligokyphus*), that is, in succession after the dentition and secondary palate but before the truly Mammalian jaw-articulation. It may, of course, be objected that we know little or nothing of the adaptive significance of the changes involved in this instance, so that their serial occurrence might well be attributed to functional necessity, each change providing a necessary prior basis for the next. The account of the evolution of the horse given by G. G. Simpson seems to offer another example; the three major shifts—that from four toes to three in the Oligocene period, that from low to high molar teeth in the Miocene, that from three toes to one in the Pliocene—apparently occurred in regular succession though there is no evident adaptive reason why the first and second, or second and third, should not have gone on concurrently.

## Physiological Forms of *Eucalyptus citriodora* Hooker

Since the discovery by Penfold and Morrison in 1927[1] of physiological forms in *Eucalyptus dives* Schau., many other examples of this phenomenon have been found in the Myrtaceæ and also the Rutaceæ[2]. The term 'physiological form' is applied to those plants in a naturally occurring population which cannot be separated on morphological evidence, but which are readily distinguished by marked differences in the chemical composition of their essential oils.

In 1948, the occurrence of a physiological form of *E. citriodora* was recorded[3] in which citronellal, the principal constituent of the 'type', had been almost entirely replaced by an equivalent amount of citronellol and its esters. The original tree in which this unusual oil was found gave a yield of 1·4 per cent of an oil containing 10·9 per cent citronellal, 33·7 per cent citronellol and 42·4 per cent esters calculated as citronellyl acetate.

Seed from open-pollinated flowers was collected from this tree, and from this seed 243 individuals were raised. Apart from a few stunted trees, the majority showed outstanding vigour and, when cut for distillation two and a half years after planting in the field (three years from sowing), averaged 16 ft. in height.

Whereas seed from the ordinary 'type' *E. citriodora* has always given progeny with a normal aldehyde oil similar to the original parent tree, in this case great variations in oil composition as well as yield were obtained on distillation and analysis. The yields varied from less than 0·1 per cent to 1·4 per cent (fresh commercial cut), and the aldehyde contents varied from nil to 82·2 per cent. Twenty-seven trees yielded insufficient oil for analysis.

It was found possible to group the oils obtained from the progeny into four series, as follows.

(1) Aldehydes 65–85 per cent, corresponding to a normal 'type' *E. citriodora*. Seventy-seven trees, equivalent to 40·1 per cent of the oils analysed, fell into this 'aldehyde inheritance' group.

(2) Aldehydes less than 30 per cent and very soluble in 70 per cent alcohol, corresponding to the original parent tree. Forty trees, or 20·8 per cent, fell into this 'alcohol – ester inheritance' group.

(3) Aldehydes less than 30 per cent but highly insoluble in 70 per cent alcohol. A total of 9·8 per cent of the oils showed this 'hydrocarbon inheritance'.

(4) Aldehydes 30–50 per cent. This group, which is intermediate between groups (1) and (2), accounted for 29·2 per cent of the oils analysed.

Before the progeny trees were ready for cutting, a further survey of the area where the original variant had been found led to the discovery of two forms corresponding to groups (3) and (4) above, as well as more trees with the alcohol–ester type of oil[4]. All these trees were found within a radius of 50 yd. from the original tree. Therefore, all four groups of oils obtained from the progeny trees have been found in Nature.

A similar occurrence to that recorded above has previously been noted in *Leptospermum citratum*[5]. The normal aldehyde oil trees always give progeny with aldehyde oils, the hydrocarbon form always gives a hydrocarbon oil; but the alcohol–ester form gives a variable progeny including alcohol–ester oils, intermediate oils and hydrocarbon oils.

Further breeding work is being carried out with the various forms in order to determine the actual mode of inheritance of these compounds. It appears likely that in both species a similar mechanism is in operation.

## Effect of Grafting on Nodulation of *Trifolium ambiguum*

THE clover *Trifolium ambiguum* is a perennial species which has a somewhat restricted natural range in the Caucasus region and the neighbouring steppes, extending westwards to about the Crimea. As an introduction in the United States, it has attracted much attention as a prospective pasture plant for more favoured northern sections because of its deep-rooting habit, capacity to spread by rhizomes and considerable degrees of both drought and winter hardiness. Furthermore, as it produces nectar freely and the corolla tube is shallow, it is of particular interest with respect to honey production. However, as a legume it has an outstanding weakness in that effective nodulation of this species has never been found. Parker[1] tested on it some thirty-five strains of *Rhizobium trifolii* and, although most of them produced a certain degree of nodulation, the nodules almost without exception were very small, quite withered, brown, unhealthy and obviously ineffective. In general, these nodules occurred at the point of origin of a small root, as though rhizobial infection of this species occurred as the result of the rupture of the root tissue by an emerging branch root, as reported by Allen and Allen[2] for *Arachis hypogea*, and not through root hairs. Normally, of course, the relationship between *Rhizobium* and plant is more positive, direct and symbiotic, the bacteria reaching the cortical tissue through an infected root hair and there causing a proliferation of cells and an appreciable development of healthy nodular tissue. In the case of nodulation effective in symbiotic nitrogen fixation, the nodules are comparatively large, plump and pinkish in colour owing to the presence within them of the product leghæmoglobin.

*Trifolium ambiguum* has been grown at this Institute under conditions which resulted in good plant growth with adequate development of root hairs and on soils in which *Trifolium repens* nodulated abundantly and well; but the former has never produced any nodules.

In view of the results obtained with *Soja hispida* by Bonnier, Hely and Manil[3], it was decided to investigate the effects of grafting *Trifolium repens* on the seedlings of *Trifolium ambiguum*. Four general types of grafts were used, and all methods gave a high percentage of successes. These comprised: (1) insertion of the growing point from a seedling or older plant of *T. repens* into the split hypocotyl of *T. ambiguum*; (2) similar insertion of a longer piece of older stem of *T. repens* which had some adventitious roots for its partial support originally; these were removed later; (3) various forms of inarch grafts on the hypocotyl of *T. ambiguum* seedlings; and (4) grafting of a complete and well-nodulated root system from a seedling of *T. repens* of about the same size on to a vigorous seedling of *T. ambiguum* in the upper root–hypocotyl region, with a reduction by pruning of some of the roots of the latter.

The findings from sixty grafted plants were as follows. (1) Grafting of either plant tops or roots of *T. repens* on to *T. ambiguum* resulted in the production of relatively large and healthy nodules on *T. ambiguum*. (2) The best results were obtained when the *T. repens* was made entirely dependent on *T. ambiguum*. (3) When a true graft was produced and the scion developed adventitious roots later, its nodules were of a large, irregular and very unusual shape for *T. repens*, and also tended to be partly green in colour although located well below the soil surface. (4) The nodules produced on *T. ambiguum* occurred on the main root and on branch roots, and either at the point of origin of a branch root or apart as though resulting from root-hair infection. (5) These nodules were comparatively large, spherical and closely resembling in form those of *T. repens*, but were white in colour and probably ineffective.

Ungrafted plants of *T. ambiguum* grown in the same pots with the above showed no evidence of nodulation in any case.

Isolations made from these nodules have been true rhizobia and have grown well on standard media; but it is not yet known if it is possible to get good nodulation directly by inoculation of plants of *T. ambiguum* grown in tubes under aseptic conditions, or whether the best results will be obtained when such material is used for inoculating plants of *T. ambiguum* again grafted with *T. repens*. However, in a late-season experiment, a small number of nodules were obtained on ungrafted *T. ambiguum* seedlings growing in pots by inoculation with material isolated from the *T. ambiguum* nodules on the grafted plants. This aspect will be investigated further.

It is considered probable that a fully effective strain of *Rhizobium* can be obtained for *T. ambiguum* by different techniques, notably by the method of successive passages through the host plant and selection of nodules obtained. However, since the development of new strains and their selection normally occur gradually in Nature, it is expected that quite a number of passages through *T. ambiguum* will be necessary before effective nodulation of this species becomes a practical possibility.

## The Respiratory Bubble of the Aquatic Beetle, *Potamodytes tuberosus*, Hinton

*Potamodytes tuberosus*, Hinton is an elmid beetle that inhabits fast-flowing water, and the present observations were made during 1952 on adult beetles occurring in a tributary of the River Densu, Gold Coast.

The bed of the river consists of large irregular rock slabs and boulders, and the fall in its level is quite rapid. During the rainy season torrential conditions prevail in the river, and the beetles were found widely distributed in the part kept under observation. During the dry season, however, the flow of water steadily decreases until the river becomes a series of rock pools and basins connected by little channels and waterfalls. It was found at this stage that although the rate of flow through the rock pools was very slow, it was comparatively fast in the connecting channels. The beetles collected in these channels, clinging to the rock surface and invariably facing the oncoming current. They were never found in slowly moving or still water, or more than an inch or two below the surface. They apparently fed on the microbiological slime that covered the submerged rock surfaces and, unless disturbed, they appeared to move but little.

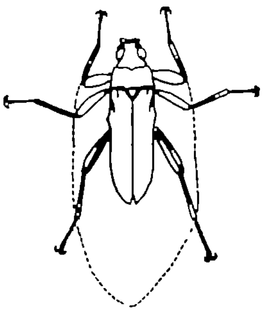

**Fig. 1.** Position of bubble, indicated by the dotted line, when the beetle is in a current of water

A conspicuous feature of the beetle is the respiratory bubble, clinging to its body and dragged out behind by the force of the current (Fig. 1). It would seem that certain characters of the beetle reduce the tendency of the bubble to be swept away by the current, and that under certain conditions it may extend for 1¼ in. behind the beetle. It was frequently noted that the water inhabited by the beetle was broken up with bubbles of air. These coalesced continually with the respiratory bubble and thus renewed its supply of air. Observation showed, however, that the beetles also inhabited flowing water which, although saturated with air at atmospheric pressure, did not contain any visible bubbles of air. It also seemed that, under these conditions, the bubble did not shrink, as might have been expected, but acted as a permanent physical gill. This was confirmed by laboratory experiments. In slowly circulating air-saturated water, the bubble gradually disappeared and the beetle died in a few hours; in an artificial current the bubble did not disappear, and on occasion, in fact, increased considerably.

The following hypothesis is put forward as a possible explanation of the permanent nature of the respiratory

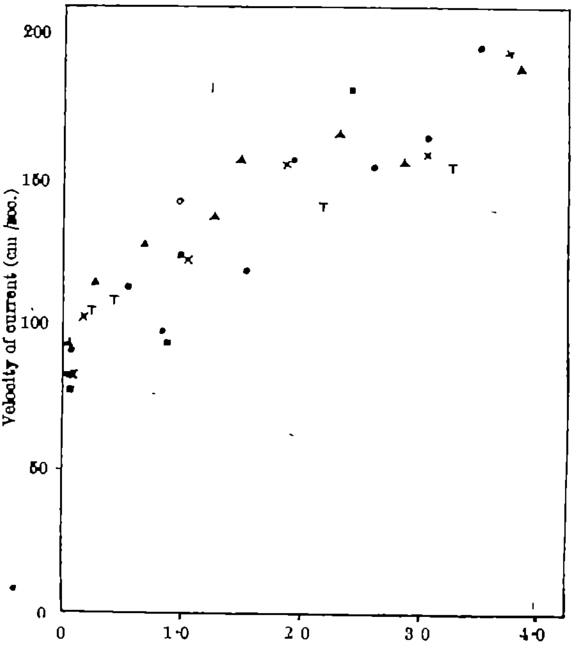

**Fig. 2.** Effect of the velocity of current on the pressure of the gas in the respiratory bubble. Observations were made on six separate beetles; each set of symbols refers to the results obtained from an individual beetle

bubble. The principle involved, which is most familiar in its application to the design of the aeroplane wing, is explained in elementary text-books on aerodynamics. Owing to the presence of the beetle, the velocity of the water immediately surrounding the beetle is increased relative to the velocity of the water in neighbouring regions. As a result, there is a reduction in pressure according to the Bernoulli equation $p + \frac{1}{2}v^2 =$ a constant. This reduction in pressure is communicated to the bubble. If the beetle is in a stream of water that has been saturated with air under atmospheric pressure, the water which enters the region of reduced pressure becomes temporarily super-saturated, with the result that some of its dissolved gases tend to pass into the bubble. The loss of nitrogen, postulated for the shrinking type of air bubble, does not apparently occur under these conditions.

The pressure of the air in the bubble was measured and the results are shown graphically in Fig. 2. It will be noted that above a certain critical velocity of the current, the pressure recorded in the bubble fell below atmospheric pressure. While not constituting absolute proof of the hypothesis put forward, it would seem that this result lends it a considerable support.

I thank Prof. J. E. Harris, University of Bristol, for discussions on this matter, and Mr. J. W. Balfour-Browne, British Museum (Natural History), London, for the identification of the beetle.

## A Predator on *Creontiades pallidus*, Ramb.

The mirid *Creontiades pallidus* is widely distributed throughout the Anglo-Egyptian Sudan; it is also recorded from Egypt and the Belgian Congo, where in both places it is a pest of cotton. Wilcox[1] reports that no parasites or predators of *C. pallidus* were known to him in Egypt; while Madame Soyer[2] found a geocorid bug to be the only predator of this mirid in the Congo. Since Soyer's paper, there appear to be no other references to the insects which attack *C. pallidus*.

For a number of years *C. pallidus* has been thought to be a pest of cotton grown in the Tokar Delta; Tokar is about a hundred miles south of Port Sudan and about thirty miles inland from the Red Sea coast. The insect occurs all along the coastal cultivations, which stretch from the northern border of Eritrea to a point approximately 175 miles north of Port Sudan. In all those places where *C. pallidus* was found on the coastal stretch, the predator *Chrysopa carnea* Steph. also appeared.

On January 18, 1952, and on two subsequent occasions on Tokar cotton, *C. carnea* larvæ were seen attacking nymphs of *C. pallidus*. The nymphs, although generally active, have the habit of resting within the bracts of cotton buds, and it was in these sites that the attacked nymphs were discovered. When confined in a specimen tube, a larva of *C. carnea* will readily feed on nymphs of up to the fourth instar. Once the predator's jaws are fixed in the prey, both insects can be killed in a cyanide bottle without the larva relaxing its hold. Two specimens prepared in this way are deposited in the British Museum (Natural History), and two more are to be found in the Collection Room of the Gezira Research Farm.

When reared through the last larval instar on a diet of *C. pallidus* nymphs, the predator pupated normally and adults emerged from the pupæ. Each *C. carnea* larva ate an average of 6·1 nymphs in the last larval instar of two days; while the greatest number of nymphs consumed by such a larva was thirteen in the space of five days.

While it is unlikely that *C. carnea* in the field subsists wholly upon a diet of *Creontiades* nymphs, it is probable this predator does check to some extent the multiplication of the mirid at Tokar.

## Purple Pigment and Protein in the Threads of the Sea Anemone, *Adamsia rondeleti*

The sea anemone, *Adamsia rondeleti*, produces coloured protein threads, from which a purple pigment can be extracted by means of distilled water. These protein threads are produced by special glandular cells of the body, and are excreted through special pores. They are used in obtaining food (small fishes or crabs), and perhaps for self-defence.

Up to now, it has not been possible to separate the pigment from the albumin with which it is conjugated without coagulating the protein, and at the same time replacing the purple colour by yellow. The purple pigment gives an intense blue fluorescence in ultra-violet light, the principal absorption maximum being at 555 mμ with smaller peaks at 465, 450 and 435 mμ. On heating, the aqueous solution becomes yellow. The purple pigment is unlikely to be 6-6′ dibromoindigotin, which has a quite different absorption spectrum. The pigment is changed to a colourless compound at pH 1·92 but persists at pH 12·36; addition of 0·1 *N* sodium hydroxide (pH 12·93), however, results in a yellow colour, and a smell of trimethylamine is noticed.

Vacuum desiccation transforms the aqueous solution into a micro-crystalline substance, and causes the purple colour to disappear, changing to yellow. In moist air the colour is restored.

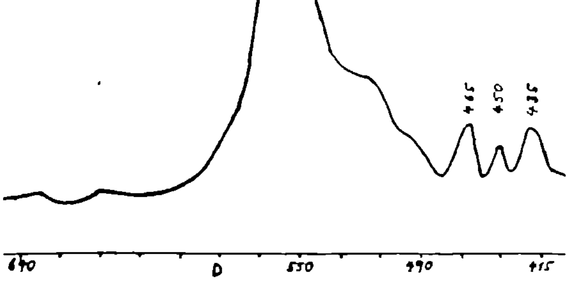

Fig. 1. Absorption spectrum of the purple pigment

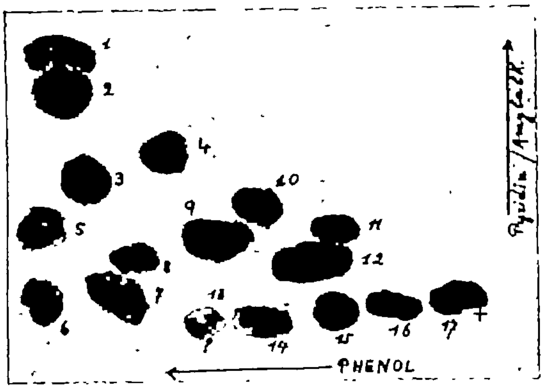

Fig. 2. Chromatogram of the purple pigment.
1, Tryptophane; 2, leucine, 3, valine; 4, tyrosine; 5, proline 6, arginine; 7, lysine; 8, histidine; 9, alanine; 10, threonine; 11, serine; 12, glycine: 13, unknown; 14, hydroxylysine?; 15, glutamic acid; 16, aspartic acid; 17, cysteic acid

The main pigment seems to belong to the group of the chromoproteins; but it might be a very intimate mixture with a protein. Further investigations are necessary.

Chromatography on filter paper shows the protein to contain the following amino-acids: cysteic, aspartic and glutamic acid, valine, alanine, histidine, threonine, serine, lysine, arginine, proline, tyrosine, tryptophane, hydroxylysine, and a further unidentified acid, together with tetramethylammonium-hydroxide (tetramin). The first three acids named are preponderant.

Fuller details of this work will be published in the *Bulletin of the Academy of Sciences, Athens*.

University, Athens. Nov. 28.

## A Further Analysis of the Polymorphism of *Drosophila polymorpha*

THE tropical species of *Drosophila*, *D. polymorpha*, is polymorphic with regard to the pattern of pigmented abdominal bands. The polymorphism is a case of balanced polymorphism, as shown in a previous paper[1]. The types are inherited as if caused by two alleles of a single autosomic gene. The dark and the light types are the homozygotes and the intermediate type is the heterozygote. The heterozygote has an adaptive value higher than that of the homozygotes. The heterosis of the intermediate type ensures the maintenance of the two alleles in the populations. The probability that the pigmentation pattern is by itself an adaptive character is very small. Another possibility to be considered is that the two main genes responsible for the pigmentation are associated with other genes through an inversion. The differences in adaptive value could, then, be due to the genes carried in the inversion as a whole.

Using a combination of over-feeding the larvæ and a low temperature, it was possible to study the chromosomes in the salivary glands of *D. polymorpha*. A total of six inversions, three autosomic and three in the *X*-chromosome, was detected. In a total of 461 individuals from three different places, 119 were inversion heterozygotes.

No correlation was found, however, between the inversions and the pigmentation. The three pattern types may be homozygous as well as heterozygous for every one of the inversions.

The two possible explanations left for the differences in adaptive value of the three types are: (*a*) pleiotropic effects of the two genes; (*b*) genes very closely linked to the pigmentation genes. In either case, this is the first instance in the genus *Drosophila* of polymorphism not connected with chromosomal aberrations.

## Behaviour of Spider Crabs in the Presence of Octopuses

AT La Rocque, in Jersey, the spring tides go out about two miles leaving many large lagoons with sandy bottoms and depths of from two to four feet of water. Here we often spear flat-fish, plaice, soles, etc., sometimes getting as many as twenty in a tide; here also may be found spider crabs (*Maia squinado*), which are often taken in Jersey for food, but which are considered out of season in the autumn.

In September last, the catches of flat-fish were down to about half a dozen, owing to the number of octopuses that continually disturbed the bottom and kept the fish moving. The spider crabs had collected into large heaps, about two feet high and three feet in diameter, with their legs so entangled as to make it difficult to separate a crab from the heap. The octopuses captured some from the outside of the masses, but the greater number survived, and day after day the heaps remained. None of the fishermen to whom I have spoken of this behaviour on the part of spider crabs had ever noticed it previously.

The octopuses have now (October) moved to deeper water, and the crabs too have disappeared to their winter quarters.

## Tertiary Ocean Bottom Temperatures

DURING the past few years, a method has been developed for determining palæotemperatures by measuring the ratio of oxygen-18 to oxygen-16 in the calcium carbonate of fossil shells[1,2].

This method is based on the fact that the relative rates of deposition of the oxygen isotopes in the calcium carbonate are a function of temperature. The temperature of deposition is thus determinable from a suitably accurate measurement of the relative abundances of the oxygen isotopes in a shell. To attain the required accuracy, mass spectrometers are employed in which carbon dioxide from the shell carbonate can be alternated at intervals of two minutes with a standard carbon dioxide gas. In this way only the difference $\delta$ in oxygen-18 concentration is measured, and an accuracy of ± 0·1 parts per thousand is attained. Experiments with shells grown at known temperatures in water of known isotopic composition[1,3] have shown that:

$$t = 16{\cdot}5 - 4{\cdot}3\,\delta + 0{\cdot}14\,\delta^2,$$

where $\delta = 1{,}000\left(\frac{R_{\text{sample}}}{R_{\text{standard}}} - 1\right)$ and $R$ is the ratio of concentration of oxygen-18 to oxygen-16. The measure of $\delta$ is relative to our carbon dioxide standard, derived from a powdered Belemnite of the Peedee formation of North Carolina.

To obtain fully reliable results, two conditions must be fulfilled: there must be equilibrium between water and the carbonate ion deposited by the animal, and the oxygen isotopic composition of the sea water must be constant in time and uniform in space.

The first condition was verified at the beginning of this project[1]. The constancy in time of the isotopic composition of the sea water may be rather safely postulated for the time being, and could possibly be verified later by analysing the oxygen isotopic composition of fossil phosphates, sulphates or silicates, of marine deposition. As for the uniformity in space, extensive analyses of different marine waters[1,3] showed that the oxygen-18 content of sea waters having a salinity range of 32–38 per thousand varies by 2·4 per thousand. This effect is more evident in superficial waters, whereas deeper waters are more uniform. Superficial differentiation in oxygen isotopes is due to the fact that the higher vapour pressure of $H_2{}^{16}O$ with respect to $H_2{}^{18}O$ favours the evaporation of the lighter water from warm seas, and its precipitation as rain, ice, or snow, in the higher latitudes[3]. A concentration of heavier water in the lower latitudes and of lighter water in the higher ones is therefore produced. This introduces an uncertainty of ± 5·5° C. in the temperatures obtained by analysing the calcium carbonate of Recent marine animals, if no correction is applied for the variations of the concentrations of oxygen isotopes in the marine waters.

Although a similar correction cannot be applied now for isotopic variations in the oceans of the past, the uncertainty of temperature measurements would be smaller if in earlier geological times ocean waters were more thoroughly mixed, so as to produce a greater uniformity in isotopic composition and, concurrently, in salinity, temperature, etc. Such a condition is thought to have been predominant in non-glacial times. In fact, in the absence of floating ice and superficial layers of cold water with lower salinity, the warm currents from low latitudes would extend to the highest latitudes. There, they would cool to some extent, sink to the bottom, and flow back to lower latitudes as deep currents. This extended activity would produce a more uniform temperature throughout, and also increase the temperature of the bottom of the oceans[4].

To verify these considerations, two samples of benthonic Foraminifera from a deep-sea core of Tertiary age were analysed for palæotemperatures. This core was obtained by the Deep-Sea Swedish Expedition of 1947–48 in the eastern central Pacific. The geographical co-ordinates of the locality are: 15° 34′ N., and 127° 11′ W. The depth of the ocean bottom is 4,725 m., and the length of the core 348 cm. The core represents a truncated sequence of Tertiary sediments[5], of probable Oligocene age. Truncation was caused by deep current abrasion or possibly by slumping. The missing part included at least 10 m. of Pleistocene and Late Pliocene sediments, and an unknown thickness of older deposits. The Foraminiferal fauna is poor. Benthonic Foraminifera are predominantly represented by Nodosariinæ in fragments and some Rotaliidæ. These Foraminifera are rather large and thick-walled, the average diameter of the larger Nodosariinæ being about 70 Dμ (1 Dμ, a length unit particularly convenient in micropalæontological work, is equal to 0·01 mm.). Pelagic Foraminifera include scarce, small Globigerinidæ.

Of the four samples from this core made available to us by Dr. G. Arrhenius, three contained enough benthonic Foraminifera for the analyses. The benthonic tests were treated according to our standard technique[6]. Microscopic examination of thin sections showed no indication of recrystallization.

The depths below the top of the core, the value of $\delta$, and the corresponding temperatures, are given in the accompanying table.

| Depth below top of core (cm.) | $\delta$ | Temperature (° C.) |
|---|---|---|
| 2–10 | 1·51 ± 0·10 | 10·3 ± 0·5 |
| 282–290 | 1·20 ± 0·10 | 11·5 ± 0·5 |
| 339–346 | 1·74 ± 0·10 | 9·4 ± 0·5 |

Post-depositional isotopic exchange between the calcium carbonate used in the tests and sea water does not seem to have occurred. In fact, if such an exchange took place, the much lower temperature of the deep sea water during the Pleistocene and the Recent would have increased the original values of $\delta$ in our material, with consequent lowering of the calculated temperatures; although probably not to the full extent, because of the influx along the bottom of polar waters having a lighter isotopic composition. Considering our results, however, it is apparent that the original temperatures could not have been much higher.

The results seem to show, therefore, that greater mixing of the oceanic waters occurred in non-glacial times and, for these periods, this gives more general validity to calculations of palæotemperatures based on our standard formula. It also adds weight to the point repeatedly stressed by geologists that the climate of the earth was much more uniform in non-glacial times.

We are indebted to Dr. G. Arrhenius for having made available to us the material from which the results presented here were obtained.

## Cosmic-Ray Intensity and the Temperature of the Upper Atmosphere

It is well known that the intensity of the hard component of the cosmic radiation at sea-level changes with changing atmospheric conditions. The existing correlation may be expressed by means of a linear equation:

$$(I - \overline{I})/\overline{I} = a(\overline{B} - B) + b(\overline{H} - H) + c(\overline{T} - T), \quad (1)$$

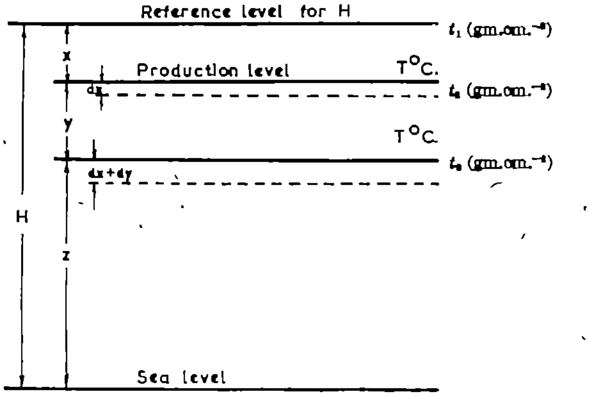
where $I$ is the intensity, $B$ is the air pressure at sea-level, $H$ is the height of the pressure level which is chosen to represent the average atmospheric depth of meson production, and $T$ is the temperature just below this level. A bar above a quantity denotes its mean value.

The first term of equation (1) is due to the absorption in the atmosphere. The second term is due to the decay of mesons in flight. The third term was first introduced by Duperier[1]. The observed positive correlation was interpreted as being due to competition between decay and capture of the π-mesons. The probability of decay into a μ-meson is:

$$P \approx 1 - \rho L_\pi / R_\pi, \qquad (2)$$

where ρ is the density of the air, $L_\pi$ is the mean range of the π-mesons before decay and $R_\pi$ is the mean free path for nuclear absorption. It is assumed that $\rho L_\pi \ll R_\pi$, as is the case in the upper atmosphere. Equation (2) shows that this effect must give rise to a positive correlation between $I$ and $T$. However, the corresponding temperature coefficient, $c_1 = dP/dT$, could not account for more than one-third of the observed effect[2].

I wish to point out and discuss two other effects which may together be responsible for the apparent discrepancy. In order to simplify the discussion, we will assume that all π-mesons are produced at the same atmospheric depth of $t_2$ gm.cm.$^{-2}$ (see diagram). Because of the short mean life of the π-mesons, most μ-mesons will be produced very close to the same level. The two other pressure-levels shown in the diagram will also be used in the discussion. The variable $H$ in equation (1) denotes the height of the level at $t_1$ gm.cm.$^{-2}$, and $T$ denotes the mean temperature between this level and that at $t_3$ gm.cm.$^{-2}$.



If the levels $t_1$ and $t_2$ do not coincide, the height of the meson-producing layer will be a function of both $H$ and $T$. This will give rise to an additional temperature coefficient:

$$c_2 = \frac{1}{L_\mu}\,\frac{dx}{dT}, \qquad (4)$$

where $L_\mu$ is the mean range of the μ-mesons before decay. If $t_2 > t_1$, then $c_2 > 0$, and vice versa.

When traversing the atmosphere, the μ-mesons lose energy, and their apparent mean life will decrease. Therefore, between the levels $t_2$ and $t_3$ the mean range $L_\mu'$ before decay will be greater than the mean range $L_\mu''$ between $t_3$ and sea-level. If now $T$ increases, the distance $y$ must increase while $z$ must decrease, which gives rise to a positive temperature effect. Hence

$$c_3 = \left(\frac{1}{L_\mu''} - \frac{1}{L_\mu'}\right)\frac{dy}{dT} \qquad (5)$$

will give an estimate of the order of magnitude of this effect.

As Duperier[2] has measured $c$ for the two cases $t_1 = 50$ mb. and $t_1 = 100$ mb., we will also calculate $c$ for these two values of $t_1$. For the same reason we chose $t_3 = 200$ mb. (1 mb. = 1·02 gm.cm.$^{-2}$). As the meson-producing radiation is absorbed exponentially[3], with a mean range of 120 gm.cm.$^{-2}$, the average depth of production is $t_2 = 120$ gm.cm.$^{-2}$. The value of $L_\mu$ has been calculated from Duperier's height coefficient[2], $b = 3{\cdot}48$ per cent per km., which gives $L_\mu = 28{\cdot}8$ km. From the known energy loss of the μ-mesons in the atmosphere, we then get $L_\mu' = 33{\cdot}4$ km, and $L_\mu'' = 28{\cdot}2$ km. Then we use the relation $L_\pi/L_\mu \approx \tau_\pi/\tau_\mu$, where $\tau_\pi$ and $\tau_\mu$ are the real mean lives of the two kinds of mesons, to obtain $L_\pi = 0{\cdot}363$ km. For $R_\pi$ we use the geometric mean free path, which is 60 gm.cm.$^{-2}$ in air. Thus we have certainly not under-estimated $c_1$. The values of $\tau_\pi$, $\tau_\mu$ and other necessary constants were taken from Rossi's recently published book[3].

The results are, in per cent per deg. C.:

|  | $t_1 = 100$ mb. | $t_1 = 50$ mb. |
|---|---|---|
| $c_1$ | 0·052 | 0·052 |
| $c_2$ | 0·019 | 0·090 |
| $c_3$ | 0·008 | 0·008 |
| $c$ | 0·079 | 0·150 |
| Duperier | 0·075 ± 0·010 | 0·143 ± 0·015 |

Duperier's results have been included for comparison. The agreement is very good. However, one must not forget that the calculations were based upon a very simplified model of the cosmic radiation. It is quite possible that the results of a more exact calculation would not agree so well with the experimental temperature coefficient; such a calculation is now in progress.

## Scatter Fringes of Equal Thickness

It is possible to test an optical system by means of white-light interference between two or more wave-fronts which have been scattered by equivalent obstacles out of the same collimated beam.

Consider, for example, an optical system in which a small portion of the field is strongly illuminated with white light. If a screen of moderate scattering power (say, a microscope slide which has been aluminized while in contact with a piece of lens tissue) is introduced into the entrance pupil, then the observer sees the remainder of the field stop illuminated by a diffuse diffracted halo. If a second exactly conjugate screen is placed in the exit pupil so that it appears identical with the image of the first screen except for imaging errors and for some relative displacement, white-light fringes are formed on the field stop by the two scattered beams.

Where the first screen is seen imaged without sensible error, for example, by a plane mirror, the fringes observed are of equal inclination, well-known examples being Newton's diffusion fringes and Quetelet's rings. If, on the other hand, the first screen is being imaged by an imperfect system and is adjusted to nominal coincidence with its fellow, corresponding fringes of equal optical thickness are produced. Light scattered by the first screen suffers distortion by the system to form the error wave-front; but the second or reference wave-front is substantially free from error since its parent beam has traversed that system in concentrated fashion. The fringe pattern therefore represents the wave-front error with which the entrance pupil is being imaged on to the exit pupil, a bright achromatic fringe covering those portions of the field for which the transit time is the same as for the directly illuminated patch.

The practical possibilities of these fringes of equal thickness do not seem to have been explored. For optical testing they have one advantage in that they do not lose contrast in the presence of considerable tilt or asphericity. Of particular interest is their application to imaging systems of unit magnification such that one screen is (1) imaged by a through type or autostigmatic system on to an identical replica; (2) imaged back on to itself enantiostigmatically; or (3) repeatedly imaged on to itself in a multiple-beam arrangement.

Preliminary experiments on the first two types suggest that the fringes may be useful for testing large mirrors, camera lenses and microscope objectives, and possibly for interference microscopy. The fact that the fringes are self-compensating for path-length and, in the second case, for odd azimuthal errors suggests various engineering applications. Further investigation is taking place.

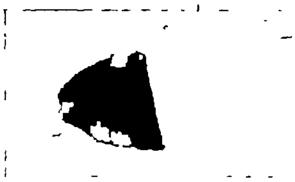
## Kramer and Russell Effects with Single Crystals of Zinc

A short while ago, Kramer[1] directed attention to the fact that abraded or worked metal surfaces emit negatively charged particles which can activate an open-ended Geiger–Müller counter operated in air. Kramer assumed the particles to be electrons, emitted owing to phase changes occurring on the freshly disturbed metal surface. Haxel, Houtermans and Seeger[2] confirmed these observations, but offered an explanation based on adsorption phenomena. Gobrecht and Barsch[3] brought forward evidence that changes of phase are not directly responsible for the phenomenon. Work at the Mechanical Engineering Research Laboratory confirmed the previous observations, but also established by measurements of ionic mobility that the particles triggering the counter are oxygen-molecule ions. It was further found that the 'active' areas behave essentially as having a lower work function than is usually ascribed to the particular metal. Abraded specimens or evaporated films gave thermionic counts at lower temperatures and photoelectric counts at longer wave-lengths than aged or unabraded surfaces of the same metal.

Experiments carried out with single crystals will illustrate this. Single crystals of zinc (kindly given to us by Dr. A. J. W. Moore) were cleaved in the (0001) plane. One of the cleaved surfaces was abraded, whereas the other was left undisturbed. Both surfaces were investigated by means of an open-ended Geiger–Müller counter operating at a pressure of 10 cm. of mercury (9 cm. mercury of air + 1 cm. mercury of ethyl alcohol). The response of the two surfaces to daylight through glass (with most of the ultra-violet wave-lengths cut off) was determined. Great care was taken to make the geometrical and illumination conditions identical in both experiments, and alternate counts were taken from the two surfaces in order to take account of the decay of the response. To eliminate stray fields from the counter, a zinc grid was interposed between counter and specimen and operated at a positive potential so that the field between the specimen and grid was 20 V./cm. Under these conditions, the cleaved surface gave 40 counts/min., whereas the cleaved and abraded surface gave 275 counts/min.

The cut-off wave-length for the photoelectric response of zinc lies normally well in the ultra-violet at about 3000 A. The fact that the cut-off wave-length had been shifted into the visible spectrum to about 5000 A. indicates that the abrasion process produces, on the surface, areas of low work function, possibly by the intermingling of oxide and metal phases.

The behaviour of the surfaces was further checked by means of the Russell effect, which, as has previously been suggested[4], is usually associated with surfaces giving Kramer counts. Another single crystal of zinc was treated as in the previous experiment. Both the cleaved and the cleaved and abraded surfaces were exposed to an Ilford *Q* plate for 20 hr. After development the image shown in the accompanying photograph was obtained. The cleaved and abraded surface gave a very dark image, whereas the cleaved surface gave scarcely any image.



(a) Cleaved (b) Cleaved and abraded

These and other experiments of similar nature lead us to believe that the abrasion of metals causes the formation of sites of low work function, and that these sites are responsible for the so-called Kramer effect.

## The New Classical Electrodynamics

Except for a gauge-fixing condition, Dirac's recent theory[1-3] corresponds to the natural form of Maxwell–Lorentz electrodynamics for very fine-grained streams of charged corpuscles all with the same constant mass $\mu$ and charge $\epsilon$; the velocity field in the stream is supposed to be continuous and differentiable. The ratio $\mu'/\epsilon$ is written $k$; here $\mu'$ is the measure of $\mu$ in energy units: $\mu' \equiv \mu c^2$. (We call this first special form of the theory the *superconductive theory*, since its equations will be seen to be entirely equivalent to those of the relativistic form of the Maxwell–London theory when only supercurrents are present. As not all electrodynamics is superconductive, this theory is insufficiently general.) It is evident intuitively that in the uniform stream theory[3], where $\mu$ and $\epsilon$ are everywhere constant, a non-trivial electrostatics is impossible; for example, it is not possible to describe as a static situation a charged dielectric, or any system with a space-charge which appears at rest macroscopically. For this and other reasons, connected with the existence of more than one kind of elementary particle, one is led to generalize the pre-quantum theory by allowing the mass $\mu$ and charge $\epsilon$ to be variable in space-time. Such a theory may be called the general stream theory, and will be considered elsewhere. Here we confine ourselves to discussing some characteristic physical consequences of (*a*) the equations of motion, and (*b*) the gauge condition of the uniform stream theory. These follow from the assumption of:

(*a*) Differentiability of the 4-velocity field $v^\alpha = dy^\alpha/ds$ under the Lorentz law of motion, that is,

$$A_{\alpha\beta}v^\beta = -k\,dv_\alpha/ds = -kv_{\alpha,\beta}v^\beta. \tag{L}$$

(*b*) The requirement that $A_\alpha - kv_\alpha$ be orthogonal to $v_\alpha$, that is,

$$A_\alpha v^\alpha = k. \tag{D}$$

Here $s$ is the proper time (in light-velocity units) along the world-line $y^\alpha$ of any corpuscle, $A_\alpha$ is the electrodynamic 4-vector potential, and $A_{\alpha\beta} \equiv A_{\beta,\alpha} - A_{\alpha,\beta}$ is the space–time curl of $A_\alpha$; the comma followed by subscript $\alpha$ indicates differentiation with respect to the space–time co-ordinate along the $\alpha$-direction.

(*a*) The expression of $dv_\alpha/ds$ as $v_{\alpha,\beta}v^\beta$ assumes that corpuscle velocities at neighbouring points in space–time have neighbouring values, and that first derivatives with respect to space and time exist (except possibly for special boundaries and points). It is interesting to note that, without some assumption of this type, grave difficulties are experienced already in the older theory when one tries to obtain the relations of macroscopic phenomenological electrodynamics by averaging over the classical electron theory in a relativistically invariant way[4].

It is convenient to introduce several abbreviations. With the ***kinetic field*** $V_\alpha \equiv kv_\alpha$, and the potential field $A_\alpha$, we may define the ***stream field***:

$$S_\alpha \equiv A_\alpha - V_\alpha. \tag{1}$$

By adding to (*L*) the expression $kv_{\beta,\alpha}v^\beta = 0$, which follows from $v_\beta v^\beta = 1$, we find that $S_{\alpha\beta}$, the space–time curl of $S_\alpha$, satisfies

$$S_{\alpha\beta}V^\beta = 0, \tag{L'}$$

while (*D*) may be written: $S_\beta V^\beta = 0$. $\quad$ (*D′*)

(*b*) The physically observable electromagnetic field $A_{\alpha\beta}$ is invariant under the addition to $A_\alpha$ of an arbitrary gradient $G_{,\alpha}$ and allows the freedom to impose a gauge condition. In the present theory, the chosen condition (*D*) relates the $A_\alpha$ to the $v^\alpha$ and hence to the observable 4-current density of classical electrodynamics. It seems most natural to interpret this current density $J^\alpha$ as the manifestation of concentration and velocity in the stream of corpuscles. Thus we may write:

$$J^\alpha = N\epsilon v^\alpha \equiv \frac{\lambda}{c^2}V^\alpha \quad \lambda \equiv c^2N\epsilon/k \equiv N\epsilon^2/\mu, \tag{2}$$

where $N$, the *corpuscle concentration*, represents at each point the number of corpuscles contained in a unit co-moving volume (that is, moving along with the local stream). $N$ (or $\lambda$) is a scalar density.

Though Dirac[1] considers that only the ratio $e/m$ $(\epsilon/\mu)$ should enter into a prequantum theory of electrodynamics, it seems rather more likely, as Born[5] has remarked, that "the classical radius of the electron" $e^2/mc^2$ should also appear; this quantity occurs in theories of phenomena which are generally regarded as classical, for example, in the (J. J. Thomson) scattering of long electromagnetic waves by loosely bound electrons. We see that, with our interpretation, the field variable $\lambda = Nc^2\,(\epsilon^2/\mu c^2)$ does indeed introduce the characteristic length $\epsilon^2/\mu c^2$ in a natural way. In fact, this length signifies the ratio of the current value associated with a moving corpuscle to its kinetic field value. In the superconductive theory, $V^\alpha = A^\alpha$, and $\lambda$ corresponds to $1/\Lambda$, where $\Lambda$ is the London parameter[6]. For an ordinary macroscopic superconductor, $\lambda \simeq 10^{31}$ sec.$^{-2}$, and, setting $\epsilon^2/\mu c^2 \simeq 3 \times 10^{-13}$ cm., we find

$$N \simeq 0{\cdot}4 \times 10^{22}\ \text{cm.}^{-3},$$

or the number of 'superconducting electrons' is of the same order of magnitude as the number of atoms in a volume element.

We turn now to the kinetic consequences of the stream theory. These may be described in the following geometrical way. Any bivector at a point in the 4-dimensional realm is representable either by a single plane patch of area or, at most, by two mutually perpendicular plane areal patches. (*L′*) means that the bivector $S_{\alpha\beta}$ is totally perpendicular to the time-like 4-vector $V^\beta$ and is therefore uniplanar and space-like. Now with the gauge condition (*D′*), $S_\beta$ is also made perpendicular to $V^\beta$. $S_\alpha$ then lies in the plane of its own curl, that is,

$$S_{\alpha\beta}S_\gamma + S_{\beta\gamma}S_\alpha + S_{\gamma\alpha}S_\beta = 0,$$

and this is the necessary and sufficient condition that, with an integrating factor, $S_\alpha$ becomes proportional to an irrotational vector:

$$S_\alpha = \xi\eta_{,\alpha}. \tag{D''}$$

This is the form which Dirac uses as the basis of his variational development[1]. It is evident that the surface $\Sigma$ determined by ($\xi$ = constant, $\eta$ = constant), at any point, is the integral manifold of (*L*) and of

$$S_\alpha dy^\alpha = \xi d\eta = 0 \tag{D'''}$$

taken together. In other words, all world-lines or path curves satisfying (*L*) and (*D*) passing through the given point lie on what formally appears to be a two-dimensional surface[3] $\Sigma$. There is an apparent difficulty here from a physical point of view in that this seems to restrict unduly the possible motions of corpuscles. This difficulty is removed when we remember that $\Sigma$ is definable by its property of being totally perpendicular to the space-like plane of $S_{\alpha\beta}$ at the given point. But $S_{\alpha\beta}$ at the given point does not define a unique plane in space-time, since it depends also on the components of the ***vorticity*** $V_{\alpha\beta}$, themselves determined by the velocity and its derivatives. In fact, in the general uniform stream theory, the variety of possible world-lines through a point is the same as that of the possible trajectories in the traditional Lorentz particle theory. The actual restriction brought in by the condition of continuity and differentiability of $V^\alpha$ appears in the initial conditions, that is, neighbouring corpuscles must be assigned neighbouring velocities, so that bundles of corpuscles may diverge or converge only in a gradual manner.

The case is otherwise in superconductive electrodynamics. The possible velocity distributions (and magnetic fields) associated with a given electric field are much more restricted. Here an eigen-function problem presents itself which will be dealt with elsewhere.

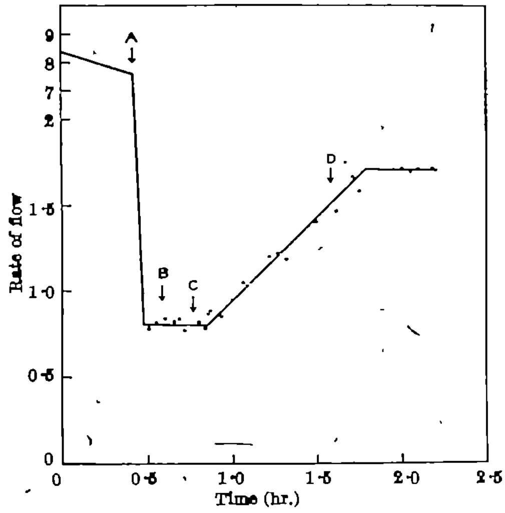
## Formation of Silicotic Tissue

ELECTRON micrographs of normal connective tissue reveal a very fine protein network superimposed on a much coarser network[1]. The interstices are filled with protofibrils and mucopolysaccharidic acids of high molecular weight. Fibrous connective tissue is produced when lung tissue is degenerated by silica particles, the silicic acid formed by the dissolution of the silica probably being involved, and the possible analogy between the role of silicic acid and that of the mucopolysaccharides is evident.

Day[2,3] has shown that the resistance of thin sheets of tissue to the passage of saline is markedly decreased when mucopolysaccharides are removed by hyalase hydrolysis, but that subsequent treatment with chondroitin sulphuric acid again reduces the tissue permeability. Using Day's technique, we find that dilute silicic acid solutions behave in a similar manner to chondroitin sulphuric acid.

The lower orifice of a vertical tube was covered with a membrane of loose connective tissue taken from a rat. Filling the tube with saline, the time required for the passage through the membrane of a predetermined volume of the solution was measured. The permeability of the membrane was low. The addition of hyaluronidase to the saline caused a considerable increase in flow; but subsequent addition of a dilute silicic acid sol restored the original low rate of flow or even rendered the membrane less permeable than it was originally. A typical result is shown in the accompanying graph.



*A*, Hyaluronidase added; *B*, saline added, *C*, silicic acid added; *D*, saline added

It is possible that when pathological changes are initiated by the inhalation of silica, silicic acid functions as an interfibrillary substance analogous to the mucopolysaccharides. The silica particle may thus take the role of the cell producing the macromolecules. In normal fibrous tissue, the mucopolysaccharides are being constantly destroyed by the mucopolysaccharases present in the tissue but are replaced by fresh mucopolysaccharides synthesized by fibroblasts[4,5]. Since there is no enzyme capable of hydrolysing the polysilicic acids formed, the polymers can be removed only by the slow process of physical solution, which is retarded as the silicic acid accumulates. Aluminium and beryllia, both producing macromolecules analogous to the polysilicic acids, can cause similar pathological changes.

We are indebted to the British Steel Founders' Association for financial assistance and to Benger Laboratories, Ltd., for gifts of hyaluronidase.

## The Department of Scientific and Industrial Research and Aslib

THE leading article in *Nature* of April 25 points out that the report for 1951–52 of the Department of Scientific and Industrial Research does not include a justification for the Department's grant to Aslib, and suggests the possibility of overlapping between Aslib and the Intelligence Division of the Department. It is right to say at once that this possibility is constantly borne in mind by the Council of Aslib, which has the advantage of close and continual contact with the Intelligence Division. Part of Aslib's activity is as a clearing-house between its own members, who include those concerned with information and library techniques in scientific and industrial and also in other fields; part consists in organizing the exchange of information on methods of documentation and publishing the results of investigations into them; part again in the promotion of training in these techniques. These things, it is believed, are outside the present scope of the Intelligence Division. In other activities—some of them carried out under contract with the Department of Scientific and Industrial Research—there is danger of overlapping; but it has been kept in mind, and it is hoped with some confidence that it has been avoided.

# FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

## Monday, May 18

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. Braithwaite: "Principles of Choice between Alternative Hypotheses".

## Monday, May 18—Wednesday, May 20

National Trades Technical Societies, Sheffield Section (at Cutler's Hall, Sheffield).—Exhibition of Laboratory Equipment.

## Tuesday, May 19

Society of Chemical Industry, Agriculture Group (in the Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.15 p.m.—Annual General Meeting; at 2.30 p.m.—Dr. H. Greene: "Tropical Soils".

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. J. Z. Young, F.R.S.: "Measurement with the Flying-Spot Microscope".

Royal Statistical Society, Study Section (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill London, W.C.2), at 6 p.m.—Mr. L. Moss: "Sample Surveys and their Use for Administrative Purposes".

## Tuesday, May 19—Friday, May 22

Institution of Gas Engineers (at Church House, Westminster, London, S.W.1).—90th Annual General Meeting.

## Wednesday, May 20

Physical Society, Colour Group (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 3.30 p.m.—Scientific Papers.

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

Royal Society of Medicine, Section of Comparative Medicine (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "Organic Manures and Fertilizers and the Production and Composition of Food for Man and Animals".

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. E. C. Bullard, F.R.S.: "The Utilization of Solar Energy".

Society of Public Analysts and Other Analytical Chemists (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

## Wednesday, May 20—Friday, May 22

European Association of Exploration Geophysicists (at the Maison des Centraux, 8 Rue Jean Goujon, Paris).—Fourth Meeting.

## Thursday, May 21

Society for Endocrinology (at the Medical Society of London, Chandos Street, London, W.1), at 9.30 a.m.—Symposium on "The Determination of Adrenal Cortical Steroids and their Metabolites".

Physical Society, Acoustics Group (joint meeting with the Royal Aeronautical Society, at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 10 a.m.—Symposium on "Aeronautical Acoustics—in particular Jet Noise".

Ross Institute of Tropical Hygiene, Industrial Advisory Committee (at the Rubber Growers' Association, 19 Fenchurch Street, London, E.C.3), at 2.15 p.m.—Discussions on "Tropical Health Problems and their Connection with Industrial Relations" (Speakers: Mr. C. R. Harrison and Prof. G. Macdonald).

Class of History of Medicine (in the Physiology Class Room, The University, Edinburgh), at 5 p.m.—Dr. Douglas Guthrie: "Trends and Fashions in Medicine". (Further Lectures on May 25, 28, June 1, 4 and 8.)

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. C. Lanczos. "Convergent Differentiation of the Fourier Series".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Mr. J. W. Y. Higgs: "The Scope of Rural Collections".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. J. C. Broom: "Leptospirosis in Tropical Countries".

## Friday, May 22

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Lawrence Bragg, F.R.S.: "The Discovery of X-Ray Diffraction by Crystals".

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Experimental Officer (with sound theoretical and practical knowledge of electronic and controlling instruments) in the Physics Department—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 53/9 (May 23).

Chemists (Scientific Officer grade, Ref. F.185/53A, and Experimental Officer grade, Ref. F.186/53A) at Ministry of Supply Research and Development Establishments at Waltham Abbey, Sevenoaks, Farnborough, Salisbury, Westcott and Aldermaston, for work in physical chemistry, modern analytical techniques, explosives, radio chemistry, and bacterial chemistry—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (May 23).

Lecturer in Aircraft Structures, an Assistant "B" in Electrical Engineering, an Assistant "A" in Engineering Drawing, a Demonstrator in Electrical Engineering and Physics, and a Demonstrator in Mechanical Engineering—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (May 23).

Lecturer in Metallurgy (with a degree in metallurgy or A.I.M., together with teaching or industrial experience) in the Chemistry Department—The Principal, Derby Technical College, Normanton Road, Derby (May 23).

Physiologist (with good honours degree in physiology, or an equivalent qualification, and research experience preferably involving the perfusion of isolated organs) for research on the physiology of lactation—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 53/3 (May 23).

Scientific Officer to assist with survey and research on soil fauna in the field and laboratory, at the Research Institute, Grange-over-Sands, Lancs—The Establishment Officer (Sc.), The Nature Conservancy, 91 Victoria Street, London, S.W.1 (May 23).

Senior Lecturer in Physics—The Registrar, College of Technology, Birmingham 1 (May 23)

Principal Scientific Officer at the R.A.F. Institute of Aviation Medicine, South Farnborough, to take charge of a small scientific unit concerned with effects of acceleration on man and animals, and to be responsible for detailed planning, from a fundamental aspect, of long-term programme of a physiological nature, dealing largely with changes in the circulation—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.420/53 (May 28).

Assistant Lecturer (Grade B) in Botany—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (May 29).

Mathematicians (Scientific Officer or Experimental Officer grades) in Ministry of Supply Research and Development Establishments at Sevenoaks, Farnborough, Amesbury and Malvern, for work in aerodynamics, aircraft structures, ballistics, radio or radar, high speed electronic calculating machines—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.117/53A (May 29)

Educational Psychologist—The Secretary for Education, County Buildings, Shrewsbury (May 30).

Lecturer in Civil Engineering (preferably with experience in structures or soil mechanics)—The Registrar, The University, Sheffield (May 30).

Lecturer in Physiology—The Registrar, King's College, Strand, London, W.C.2 (May 30).

Mechanical and Aeronautical Engineers in the Ministry of Supply Research and Development Establishments at Farnborough, Sevenoaks, Chertsey and Amesbury, for research work on (Ref O.240/53A) aircraft and associated equipment; (Ref. O.245/53A) gas turbine engines and design work on (Ref. O.246/53A) armaments; (Ref. O.247/53A) wheeled and tracked vehicles—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (May 30).

Scientific Officer (with a first- or second-class honours degree or equivalent in metallurgy) at a Ministry of Supply establishment in South-East London—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.159/53A (May 30).

Esso Studentship in Chemical Engineering—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7 (June 1).

Lecturer in Geology and Mineralogy—The Secretary, The University, Aberdeen (June 1).

Guinness Research Fellowship in Microbiological Chemistry—The Whitley Professor, Department of Biochemistry, The University, South Parks Road, Oxford (June 6).

Head of the Civil and Mechanical Engineering Department—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (June 6).

Lecturer in Agricultural Botany at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 6).

Lecturer or Assistant Lecturer in Philosophy, and a Senior Lecturer or Lecturer in Chemistry, at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 6).

Scientific Officers (2) at the Forest Products Research Laboratory, Princes Risborough, for research on wood bending and seasoning—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.99/53 (June 6).

Chemist (with good honours degree, or equivalent) for analytical investigational work in the Coal Survey Laboratory, Chester—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT./630 (June 8).

Electronic Apprenticeships at the Telecommunications Research Establishment and the Radar Research and Development Establishment, Malvern—The Ministry of Supply, D.T.O. (Industrial), 66-72, Gower Street, London, W.C.1 (June 8).

Principal Scientific Officer in the Intelligence Division, Department of Scientific and Industrial Research, London—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4204/53 (June 10).

LECTURER IN CHEMISTRY (preferably with special knowledge of agricultural chemistry)—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon (June 13).

ESSO STUDENTSHIP IN CHEMICAL ENGINEERING—The Registrar, The University, Birmingham (June 15).

CIVIL ENGINEERS in Government Defence Departments—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.64–65/53 (June 30).

DAVID BROWN SCHOLARSHIP IN AGRICULTURAL ENGINEERING—The Registrar, King's College, Newcastle-upon-Tyne (July 15).

MYCOLOGISTS (3) (with good honours degree in botany, preferably with systematic mycology as a special subject, and some experience in identifying micro-fungi) at the Commonwealth Mycological Institute—The Secretary, Commonwealth Agricultural Bureaux, Farnham Royal, Bucks (July 15).

ASSISTANT LECTURER (primarily interested in microbiological chemistry or cell biochemistry) IN THE DEPARTMENT OF MICROBIOLOGY—The Registrar, The University, Reading (July 18).

ASSISTANT (graduate in metallurgy, physics, or chemistry) IN THE INFORMATION DEPARTMENT—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

ASSISTANT ENGINEER IN THE HYDROLOGICAL SURVEY DEPARTMENT, Uganda—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.189/9/01.

ASSISTANT ENGINEERS IN THE PUBLIC WORKS DEPARTMENT, Tanganyika—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.112/8/03.

ASSISTANT LECTURER (Grade B) IN BIOLOGICAL SUBJECTS in the Department of Chemistry and Applied Chemistry—The Principal, Royal Technical College, Salford, 5.

ASSISTANT METEOROLOGIST (with at least three years experience in forecasting for aviation) to the Gold Coast Government—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M3B/33547/NF.

BIOCHEMIST (with mature and varied experience in isolation of pure substances from biological materials) to develop and apply biological methods to synthesis of compounds labelled with Carbon 14 and other radioactive isotopes (Ref. F.180/53A); and CHEMISTS (with good all-round laboratory experience in inorganic, organic or analytical chemistry) for duties concerned with synthesis of compounds labelled with radioactive isotopes by chemical and biological methods, extraction of radioactive isotopes from irradiated materials at high levels of activity, production of radioactive appliances for medical and industrial use, associated analytical problems (Ref. F.182/53A); at the Ministry of Supply Radiochemical Centre, Amersham—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

BIOCHEMIST (senior grade) at the County Hospital—The Secretary, York "A" and Tadcaster Hospital Management Committee, Bootham Park, York.

CHEMIST OR PHYSICIST (with good honours degree) for interesting work on problems associated with the hardening of Portland cement—The Controller, Cement and Concrete Association Research Station, Wexham Springs, Stoke Poges, Bucks.

DESIGN ENGINEERS in the Ministry of Supply at Harwell, to assist on design problems of control and instrumentation for new types of reactors—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.186/53A.

ENGINEER (Mechanical) in the Ministry of Supply at Harwell to work on mechanical design and specification of new types of reactors—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.252/53A.

ENGINEERS (electrical) to assist design, planning, construction, of electrical plant and services for large new project, at Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.187/53A.

ENTOMOLOGIST (with at least second-class honours degree in entomology) in the British Solomon Islands Protectorate—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.87/45/01.

EXECUTIVE ENGINEER IN THE PUBLIC WORKS DEPARTMENT, Fiji—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.112/49/02

INDUSTRIAL CHEMIST at Harwell to assist in problems associated with treatment of radioactive material, water supplies, and general chemical service—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.170/53A.

LECTURER IN PHYSICS, and an ASSISTANT LECTURER IN ZOOLOGY (Grade B or Grade A), at Brighton Technical College—The Director of Education, 54 Old Steine, Brighton 1.

LECTURER IN PHYSIOLOGY AND PHARMACOLOGY—The Registrar, The University, Nottingham.

LECTURER in PURE MATHEMATICS—The Head of Mathematics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7.

METALLURGIST (graduate or A.I.M.) to undertake research on improved tin alloys—The Director, Tin Research Institute, Fraser Road, Perivale, Greenford.

PHYSICIST (of graduate or equivalent standing) for work involving the application of physical methods to dust problems and to metallurgical research, and a METALLURGIST (of graduate or equivalent standing) in connexion with a programme of work relating to the establishment of basic data on the physical and mechanical properties of steel in cast form—The Director, British Steel Castings Research Association, Broomgrove Lodge, Sheffield 10.

SENIOR LECTURER IN PHYSICS—The Secretary, Royal Technical College, Glasgow.

SENIOR MECHANICAL AND ELECTRICAL ENGINEER in the Public Works Department, Sudan—The Sudan Agent in London, Sudan House, Cleveland Row, London, S.W.1, quoting 'M/E Engineer 1813'.

SENIOR SCIENTIFIC OFFICER (Ref. C.237/53A) to be responsible to Head of Fundamental Studies Group for leading team engaged on fundamental engineering design studies for new types of nuclear reactors, and SCIENTIFIC OFFICERS (Ref. C.238/53A) to assist in these studies, at the Atomic Energy Research Establishment, Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref No.

Fog Fever Syndrome in Parasitic Bronchitis.—J. F. Michel 940
Transliteration of Cyrillic Script.—M. Aurousseau . 940

# STATE SUPPORT FOR SCIENTIFIC RESEARCH

THE National Science Foundation was established in the United States in 1950, and is, in some of its functions, the counterpart of the Department of Scientific and Industrial Research in Great Britain. Thus it awards a substantial number of scholarships and graduate fellowships in the sciences, promotes the exchange of scientific information, assesses scientific investigations undertaken by Federal establishments and so on. The allocation of Federal monies for research purposes is in the hands of the National Science Board, consisting of twenty-four persons eminent in science, medicine, engineering, agriculture, education or public affairs; these men, and the executive director of the Board, are appointed by the President of the United States and the appointments are confirmed by the Senate. The first chairman of the Board was Dr. J. B. Conant, now U.S. High Commissioner in Western Germany.

The second annual report of the National Science Foundation*, for the fiscal year 1952, has a foreword by Dr. C. I. Barnard, now chairman of the National Science Board, who insists that the present restriction of appropriations to a maximum of 15 million dollars in any year seriously limits the capacity of the Foundation for carrying out effectively its statutory directives; sufficient funds for the full development of the potential scientific man-power resources of the United States have not been available, and Dr. Barnard maintains that man-power is the critical factor. The proportion of the population potentially capable of assimilating the training required of scientists, or possessing the curiosity, interest and ambition to pursue effective scientific careers, is strictly limited compared with the need for such trained individuals in the development of fundamental science. Moreover, social organization and scientific development have now much reduced earlier limitations on the rate at which practical results could be expected to come from the application of science; and this justifies a greater expenditure of man-power, resources and money solely for the extension of knowledge and development of fundamental scientific ideas for their potential, if not immediately apparent, practical significance.

Dr. Barnard's generalization that we have reached the stage when the maintenance of an expanding pool of tested scientific knowledge is good economics, as well as indispensable in the effective utilization of the world's natural resources for the needs of an increasing and under-nourished population, and essential for military or economic security, is as valid in Great Britain as in the United States; though with the reservation that, in Great Britain, finance and economic resources are perhaps of greater significance than, as in the United States, man-power. Nor would it appear that the significance of fundamental science for our national life, indeed for our international interests, is better understood in Britain than in the United States. Dr. Barnard can find greater encouragement in the support of the scientific community during the Foundation's difficult initial period than could the Advisory Council for Scientific and Industrial Research in its recent report. Neither the Department nor the Foundation can hope to be effective without the active support of scientists and of their institutions.

---

* Second Annual Report of the National Science Foundation, Fiscal Year 1952. Pp. viii+77. (Washington, D.C.: Government Printing Office, 1953.) 30 cents.

Dr. Barnard refers also to the danger, inherent in any government organization for promoting basic science, which lies in its propensity to exercise the kind and degree of control appropriate to research and development more closely related to immediate practical ends. That danger is known in Great Britain, and here again the chief safeguard, as he remarks, in addition to the integrity and understanding of the director and members of the Board, is the extensive, active co-operation of scientists in general. Like the Department of Scientific and Industrial Research with its advisory boards and assessors, the Foundation depends for wise judgment of the merits of scientific research proposals upon the personal advice of those most competent and respected in their various fields, and the collaboration of scientists is also indispensable to the Foundation in evaluating scientific progress and scientific needs. This is a task of great delicacy, and in seeking, as required by the Act, to evaluate scientific progress and locate fields that need scientific development, the Foundation must rely upon such collaboration if it is to avoid the dangers of indirect control, too strict adherence to scientific orthodoxy or discouragement of independent research in fields of great potential importance.

Apart from its operational responsibilities for the support of basic research in the sciences, the encouragement of young scientific talent by the award of graduate fellowships, the improvement of science teaching and broadening the flow of scientific information, for which the Foundation has had to devise suitable and effective techniques, the report records definite progress by the Foundation in both the fact-gathering and the analytical phases of policy development. During the year, the Foundation started, as the first of a continuing series of fact-gathering studies under a newly established Programme Analysis Office, to compile statistical information on Federal obligations for research and development at non-profit institutions. Other studies will be concerned with the organization of Federal agencies for research administration and with their budgets for research and development, the content of their research programmes and the impact of Federal support of research upon industrial development and upon colleges and universities in the United States. The Foundation is also supporting an investigation by the American Physiological Society on the content and scope of the physiological sciences, the role of physiology in the realm of education, the professional personnel in the field and the scientific contribution which may be expected of physiology over the next few years and present plans to achieve it.

Besides this, the Foundation has undertaken some short-range studies on scientific topics which are urgent from the point of view of national defence, welfare or scientific promise. The aim in such studies is to determine the extent and kind of Federal support and the outline of basic research needed to make the most rapid progress. Examples cited are the studies of the status, need and potentialities of basic research in high-temperature physics, chemistry and metallurgy, and on the utilization of solar energy from the point of view of both the biological and the physical sciences. The Foundation is also making a full inventory of existing scientific and technical knowledge and research on techniques and instruments for exploration for minerals.

Even this brief summary indicates that, in framing both its short-term and its long-term policy, the National Science Foundation is going far beyond the surveys in 1938 and 1940 of the National Resources Committee and the National Resources Planning Board, respectively, and is covering ground that in Great Britain, at least in part, is dealt with by the Advisory Council on Scientific Policy and by the Select Committee on Estimates, for example, in its report during the session 1946–47 on expenditure on research and development. As the President of the United States emphasized in a message to Congress in January 1952, on the basis of these studies the Foundation will formulate a broad national policy designed to assure that the scope and the quality of basic research in the United States are adequate for national security and technological progress. The Foundation is responsible for a continuing analysis of the whole national effort in basic research, including the evaluation of the research programmes of other Federal agencies.

Although this conception follows the recommendations of the Hoover Commission, it does not appear that support for such a policy is any more firmly assured in the United States than in Britain. The preliminary figures from its survey of the national research effort quoted in this report indicate that the national expenditure on scientific research and development in 1952 was about 3,000 million dollars, of which nearly two-thirds came from the Federal Government, one-third from industry and three per cent from universities. The greater part of this expenditure, and, accordingly, of the available research facilities and specialized man-power, is committed to specific programmes, such as the discovery of new products and cheaper or more efficient processes.

This position is regarded by the Foundation as a serious threat to the security and future well-being of the United States. Great advances in science have seldom come from such applied research, and, in the view of the Foundation and its advisory groups, the corner-stone of national scientific policy is to secure adequate support, in terms of scientific workers and facilities, as well as funds, for basic research in the sciences. The Foundation, moreover, is intended to become, ultimately, the principal agency through which the Federal Government gives support to basic research that is not directly related to the statutory functions of other Federal agencies, and specifically it is responsible for stimulating or sponsoring basic research in subjects which might otherwise receive insufficient attention. Adequate general support of basic research and training in the sciences constitute, the Foundation remarks in this report, a defence in depth which is essential for the establishment and maintenance of technological supremacy—or perhaps one might better say, excellence.

By the end of 1952 the Foundation was in a position to take the lead in Federal support of basic research, both by considering support of such research in fields receiving inadequate attention and by stimulating or sponsoring such research in scientific subjects of general importance to other Federal agencies. In doing this, however, the Foundation fully recognizes the extent to which success in framing a national science policy depends upon the full co-operation of scientific men in educational institutions, in industry and in the Federal Government service. It claims no monopoly of constructive thinking on these problems; but it is already clear that the Foundation's assertion that it can accelerate the formulation of policy and buttress scientific progress, particularly to meet the unique requirements of the United States, is fully justified. The Foundation points out that, as a country, the United States do not fully appreciate the importance of basic research to technology, tending to reverse the technological sequence—basic research, applied research, development. When all allowance is made for differing conditions in the United States, the experience of the Foundation cannot fail to provide much that is helpful as well as interesting to those responsible for the formulation of scientific policy in Great Britain. The progress of the National Science Foundation and the success of its efforts to correct the lack of balance, especially in times of crisis, between the support of basic research and applied research and development, will be watched and followed with keen interest.

# THE PROGRESS OF ELECTRONICS

Advances in Electronics

Edited by L. Marton. Vol. 3; pp. xii+357; 7.50 dollars. Vol. 4; pp. x+344; 7.80 dollars.
(New York: Academic Press, Inc.; London: Academic Books, Ltd., 1951–52.)

ALTHOUGH there has been a certain amount of resistance to its introduction on the part of physicists and electrical engineers, the term 'electronics' has now become well established as somewhat loosely defining a portion of the field of electrical science. The developments that have taken place in this subject during the past decade or so have been so rapid and extensive that the description of the results achieved occupies a relatively large portion of the scientific and technical literature of the present time. It was with the object of producing a guide to the research worker anxious to acquaint himself with advances in related fields that publication began a few years ago of a series of volumes entitled "Advances in Electronics" under the editorship of Mr. L. Marton, of the National Bureau of Standards, Washington, D.C. The first volume was published in 1949 (see *Nature*, 163, 893; 1949) and was followed a year later by Vol. 2 (*Nature*, 169, 50; 1952).

In the preface to the first volume, an explanation is given of the difficulty which confronted the board of editors in defining the scope of the subject with which they intended to deal. It was decided to limit the scope of their work to the publication of critical and integrated reviews of specific topics in the field of physical electronics and in selected branches of engineering electronics. In connexion with the latter, it was desired to keep to a reasonable minimum discussion of the instrumental and circuit techniques which are associated with electronic devices and which form the subject of a large part of the current technical periodical literature.

In view of the fact that Vol. 3 in the series was published in the first half of 1951, and Vol. 4 late last year, it would seem that it is the ambition or intention of the editorial board to make this an annual series. Furthermore, it is to be noted that, whereas in the first volume all the contributors were drawn from the United States of America, some of the contributions in the two latest volumes are by eminent men of science and engineers in Britain and France.

The first contribution in Vol. 3 is on field emission microscopy, by F. Ashworth, and this summarizes the experience gained in the investigation of the possibilities of the field-emission microscope, which under suitable conditions may achieve resolving powers of atomic dimensions and magnifications up to a million. The next chapter, on velocity-modulated tubes, brings together the combined experience of four workers in France and California in a review of the theory and mode of operation of the klystron which has proved so useful in the generation and amplification of electrical oscillations at frequencies from a few hundred megacycles per second upwards. There follow two papers on the electronic theory of the plane magnetron, by L. Brillouin, and of the cylindrical magnetron, by L. Brillouin and F. Bloch; these should prove useful to those concerned with the design and development of this type of tube, which seems almost indispensable for the generation of considerable powers at extremely high frequencies. The more practical developments in small electronic components are dealt with in two contributions from the National Bureau of Standards under the titles of tube miniaturization, by J. E. White, and subminiaturization techniques, by G. Shapiro. The last three contributions are more directly related to some of the developments in modern electrical communications, and the ever-present problem of securing an adequate signal as free as possible from any accompanying and disturbing noise. The principles of pulse code modulation are reviewed by H. F. Mayer; modern methods of network synthesis are summarized by E. A. Guillemin; and a timely and useful critical examination of communication theory is presented by M. Leifer and W. F. Schreiber as a conclusion to the volume.

The fourth and most recent volume opens with a theoretical paper on electron scattering in solids, by Prof. H. S. W. Massey, who discusses elastic and inelastic scattering of fast electrons in solids and also multiple scattering and diffusion, and the relative importance of the different processes which determine the electrical resistance of metals, alloys and semiconductors. Next follows a contribution by G. A. Morton on the scintillation counter, one of the most valuable tools in the field of nuclear research for the detection of high-energy radiations. This discussion indicates the general principles of the phosphor crystal radiation-detector, and its uses and limitations for counter purposes. The article should prove a useful starting-point to those concerned with improving the performance and reliability and the range of applications of the scintillation-counter. The random motion of free electrons in a conductor or the emission of electrons by the cathode of a vacuum tube gives rise to those spontaneous fluctuations of electricity now generally known as 'noise'. In an article on fluctuation phenomena, A. van der Ziel reviews the Fourier analysis of the subject and the application of the phenomena to various generators, including vacuum and gas-discharge tubes, and crystal diodes and transistors. The scope of the subject covered is perhaps indicated by the fact that the list of references at the end of the contribution includes ten books, seven review papers and some ninety original papers. The subject of electronic digital computers is next dealt with by C. V. L. Smith, who reviews the recent development of high-speed automatically sequenced computers. This article includes a description of the machines developed in the United States known as 'Whirlwind', with its special electronic storage tube, and 'SEAC', which at present uses mercury line storage but is so constructed as to permit the later incorporation of cathode-ray-tube storage on the principles developed by F. C. Williams in Great Britain. The magnetron valve again receives attention in this series with a very practical paper entitled modulation of continuous-wave magnetrons, by J. S. Donal, jun. The last two papers in Vol. 4 also strike a more practical and novel note in dealing with, respectively, the magnetic airborne detector, by W. E. Fromm, and multi-channel radio telemetering, by M. G. Pawley and W. E. Triest. The development of both these subjects originated during the Second World War; but it is clear that there are civil applications of the instruments and techniques described, and it is most useful to have these reviews of the progress made during the past decade.

In most cases the contributions in both volumes are accompanied by a selected bibliography which will be valuable in guiding the research student to more detailed knowledge where he desires to seek it. The volumes are very well presented in a uniform style, and there is no doubt that the editor and his advisory board are rendering a great service to the scientific community in presenting this series, which will find an important place on our bookshelves.

R. L. Smith-Rose

# ECONOMIC PLANTS OF THE WORLD

## Economic Botany

A Textbook of Useful Plants and Plant Products. By Albert F. Hill. (McGraw-Hill Publications in the Botanical Sciences.) Second edition. Pp. xii+560. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 59*s*. 6*d*.

EVERYTHING that helps towards a fuller realization and better understanding of our dependence on the plant world is of value to-day, and the second edition of Dr. A. F. Hill's well-known book will therefore be welcomed not only for itself but also for its considerable contribution towards this end.

The book may be described, like its predecessor, as an invaluable compendium of useful information about useful plants, presented in a way which, though perhaps a little staccato for some tastes, is both direct and simple. In general form it closely repeats the first edition, but it has been brought generally up to date and particularly so with regard to such matters as rubber, antibiotics, artificial fibres, new drugs and so on. A noteworthy addition is a very clear diagram illustrating the modern chemical utilizations of wood.

It is the easiest thing in the world to reproach a book for not being what its author never intended it to be, and Dr. Hill makes it plain that he does not essay to deal with many of the economic and social problems of his subject; but it must nevertheless be admitted that the first pages of the introductory chapter, which is entitled "The Importance and Nature of Plant Products", do something less than justice to the rest of the book. There is a certain bleakness about them, and a slightly more humanistic approach would not only help to illumine the main body of the book, but would also put into truer perspective some of the author's comments on certain agricultural policies and practices. Similarly, in the new preface the emphasis is on plants as strategic materials rather than on their significance as one of the potential ultimate sources of world prosperity and tranquillity. It is this emphasis again, perhaps, that accounts for the rather unexpected order of treatment in the main text, which, beginning with the industrial plant-products such as fibres, wood, rubber and the rest, goes on then to drugs and leaves food supplies until the last. But as regards this book, these are matters of form rather than substance; and although they may involve some difference of opinion, they do not detract from the achievement in Dr. Hill's valuable work. It is a book which claims a rightful place not only in every botanical library but in many others also.

Ronald Good

# SCIENCE APPLIED TO FOOD

## Food Science

A Symposium on Quality and Preservation of Foods. Edited by Dr. E. C. Bate-Smith and T. N. Morris. Pp. xvii+319+17 plates. (Cambridge: At the University Press, 1952.) 40*s*. net.

TO the scientific worker concerned with the study of food this book is of particular interest and value in that it deals mainly with the chemistry and biology of food materials, with little ordinary technological matter.

The book is, as the editors state, "a collection of lectures by contributors each of whom is an authority in his own field", and is not offered as a comprehensive text-book of food science. It is such study of the fundamentals of food science that is properly the function of the State-owned research stations—and this aspect is a predominant feature in these lectures, which give clearly and concisely a record bringing up to date our scientific knowledge of the subjects discussed. The contributions are written in a simple, logical and direct manner, and the information is given briefly yet with adequate explanation. The style of composition is pleasing and is the same in all chapters, giving a sense of uniformity throughout the book.

The book is incomplete as a text-book on food science; but it does cover a large and a very important part of the subject. This will be realized from its contents, which consist of a well-balanced and thoughtful introduction followed by successive chapters on economics, supply and distribution of foods in the United Kingdom; the principal foodstuffs—meat, fish, eggs, fresh fruit and vegetables, potatoes and cereals; the basic constituents of foods—proteins, mucopolysaccharides and mucoproteins, carbohydrates and fats; some aspects of quality in foods; the micro-organisms; chemical mechanisms of spoilage; and the principles of food preservation. No chapter of the book gives a full account of the subject discussed—indeed, this would necessitate a book on each—but what is done is to give information and explanation which should advance the intelligent application of science to the study and the industry of food.

Though the standard of information and description is in general a high one which can be properly understood and appreciated only by those who have considerable scientific knowledge and some experience of food science, there are included matters such as data and statements on well-known technical procedures which, though perhaps essentials of the course of lectures, are not so valuable in a book of this standard. This is noticeable especially in Chapter 7 on "The Principles of Food Preservation", which consists largely of such matter, and markedly so in the section on sugar preserves, no doubt because sugars are relatively simple and well-understood constituents of food and because, too, new work in this subject is more associated with their analytical separation and measurement—which matters do not come within the purview of this book. One point of criticism is that the reader may feel, as I certainly did, that in some of the sections there are too many references quoted, many of which seem unnecessary.

E. B. HUGHES

# VESALIUS ON THE BRAIN

## Vesalius on the Human Brain

Introduction, Translation of Text, Translation of Descriptions of Figures, Notes to the Translations, Figures. By Charles Singer. (Publications of the Wellcome Historical Medical Museum, New Series, No. 4.) Pp. xxvi+152. (London, New York and Toronto: Oxford University Press, 1952.) 21*s*. net.

THE writer of this review is conscious that its title may be perverted into a *double entendre*, and indeed it does recall the following incident. When Harvey Cushing was staying with Osler at his Oxford house, familiarly known as "The Open Arms", a visitor who called to see them was told by Lady Osler that the two Vesalius lunatics were in the Bodleian Library. To these two romantic disciples of Vesalius may now be added a third, in the formidable person of Dr. Charles Singer.

A detailed annotated translation into English or other modern language of the whole of the "Fabrica" of Vesalius is long overdue, although it could not fail to be a profitable enterprise, and its paramount importance to the historian of science is only too evident. The difficulty of the undertaking, however, amply explains the delay. In fact, it seems as if nothing short of a panel of scholars would suffice for the task. Vesalius's Latin is often bewildering, and his meaning may be so obscure as to call for very free and imaginative translation, nor does he always acknowledge his debts to predecessors. Hence the translators must be able to command a knowledge of the history of anatomy as it came down to Vesalius from the time of the Greeks. A few of the figures are also incomprehensible, and even so learned and experienced an interpreter as Dr. Singer is constrained to give them up. Some translation has already been attempted. We have a beautifully printed French version by Verschaffelt of the first six chapters (Haarlem, 1924), English translations of the last chapter and the preface by Farrington (1931–32), German and three Dutch translations of the Epitome (1543, 1569, 1583–86, 1647), English translation by Saunders and O'Malley of Lib. I, Chap. 39 (1946), English translation of the captions of the figures by Saunders and O'Malley (1950), English translation of the Epitome by Lind and Asling (1949), and minor fragments by Lambert and Hotchkiss (1935, 1942). These, however, touch no more than the fringe of the task, and most of them lack the indispensable commentary.

Dr. Singer's translation is based on the first edition of the "Fabrica"; but the second edition has been drawn upon for corrections and additions. These are the only editions for which Vesalius himself was responsible. If we may assume that the high standard of Dr. Singer's edition will be maintained in the complete work, we shall have a modern version of the "Fabrica" of the utmost value, since it could no longer be excusable to consult the illustrations without studying the text.

The present monograph opens with an introduction, in which the author extols the "Fabrica" as one of the great achievements of the human spirit. Its beautiful figures, he says, are Vesalius's most permanent contribution to science, and they establish exact graphic treatment as an essential adjunct of biological research, and as the *causa causans* of the organic sciences. He, however, emphasizes that Vesalius's anatomy is by no means all human. For example, the vascular system is derived from various animals, and may be roughly described as the venous system of ungulates and the arterial system of monkeys. The Introduction includes a brief analysis of the seven books of the "Fabrica", its 'tiresome' Ciceronian literary style, Vesalius as a physiological Galenist, and Vesalius as a discoverer and his debts to his predecessors, especially in regard to his work on the brain. The excellent diagram of Galen's physiological system on p. xix fails to show, what Dr. Singer, of course, knows full well, that the pulmonary artery and precaval vein are afferent and efferent to the heart according to Galen, and that the anterior projection of the "rete mirabile" is the modern chorioid plexus of the lateral ventricle.

The Introduction is followed by the English translation of Chapters 1–12 and 18 of Book 7, which deal with the brain and its dissection, after which come Dr. Singer's instructive notes and comments. Finally all Vesalius's figures of the brain are reproduced and their captions translated, to which are added some pre-Vesalian brain figures by Laurentius (1518), Berengarius (1523), Dryander (1536) and Stephanus (published 1545).

Dr. Singer is to be warmly congratulated on this highly important addition to the Vesalian corpus.

F. J. COLE

## The Philosophy of the Enlightenment

By Ernst Cassirer. Translated by Fritz C. A. Koelln and James P. Pettegrove. Pp. xiii+366. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1951.) 40s. net.

THIS is a translation of Prof. Ernst Cassirer's "Die Philosophie der Aufklärung" (1932). It is very welcome, and the Princeton University Press has produced a result in keeping with a great theme. The first three chapters give the 'feel' of the Enlightenment, whereas the rest offer more specific information. The appropriate headings comprise religion; the conquest of the historical world; law, State and society; fundamental problems of æsthetics. In all this the reader is confronted by the age of reason, an age bubbling with enthusiasm and seemingly indifferent to the existence of any situation incapable of a purely rational solution. Yet historically it was the heir apparent rather than the heir presumptive (for those having eyes to see) of the Renaissance and the Reformation.

To French clarity of thought, the pedigree must have seemed wholly adequate; to British minds, less shaken by the Reformation, its appeal was perhaps more formative than doctrinal. But in any event, philosophy had come back, true to type, as a way of life, self-liberated from the academic prison. It was to swell over everything, conquering and to conquer. The epoch cannot, however, be described as basically irreligious (as Prof. Cassirer says, undiluted scepticism could never have achieved so much); rather was the tendency one towards transcendentalism, especially in Germany. The paradox of the Enlightenment remains—its rejection of much of the past, coupled with the remarkable stability of a subsequent system founded essentially upon the outcome of a series of severe, and often painful, operations.

F. I. G. RAWLINS

## Medieval Logic

An Outline of its Development from 1250 to c. 1400. By Philotheus Boehner. Pp. xvii+130. (Manchester: Manchester University Press, 1952.) 12s. 6d. net.

THE author of this valuable historical study modestly claims that he is pointing to a gap in our common knowledge, not filling it; but, in fact, he does a good deal more. His aim is to show two things: that the traditional logic of the text-books, including those of the neo-scholastics, contains no more than part of the medieval logic; and that twentieth-century symbolic logic is a development on the same lines as the part that has been missed out, and in no sense in opposition to medieval ideas as some of its exponents have imagined. It was Kant, not the medievals, who alleged that logic had sprung perfect and fully armed from the brain of Aristotle, as Athena from the head of Zeus. Their view, Father Boehner claims, was that Aristotle had devised the "Ars Vetus" and that they were devising the "Ars Nova", continuing, developing and completing what he had successfully begun. The difficulty for the student of the present day is that so much of the work of the thirteenth and fourteenth centuries is inaccessible; some of it exists only in the form of a single manuscript.

The medieval thinkers developed a theory of 'supposition', of what terms stand for and what substitutions can be made, and also a theory of 'consequences', of the relation 'if—then'. William of Ockham, it appears, used the notion of 'material implication', commonly believed to be the invention of Lord Russell. Most of their ideas go easily and very conveniently into modern notation. Father Boehner makes a useful comment on this point. "Modern logic has made a decided step forward in assuming only a few constants which serve the purpose of bringing about an extremely simplified language. With these constants, their definitions and the rules governing their use, the scholastic theory of supposition has disappeared. It has vanished, however, at the cost of creating a new terminology foreign to that of any ordinary language. Though the language of logic has gained in clarity and precision, it has not been without a price."

A. D. R.

## Practical Chemistry for Schools and Intermediate Students

By J. W. Davis. Pp. xxiv+815. (London: John Murray (Publishers), Ltd., 1952.) 15s. 6d.

THIS book describes more than a sufficient number of chemistry experiments to meet the requirements of the General Certificate of Education of both the Ordinary and Advanced level. Much of the material is off the beaten track, for the author, Mr. J. W. Davis, is known among teachers for his resourcefulness and his novel ideas. Mr. Davis dispenses with chapters and divides his matter into sections, to which he devotes the following number of pages: general chemistry, 71; qualitative analysis, 29; volumetric analysis, 68; preparations (organic and inorganic), 108; and miscellaneous, 33. The last section should be especially interesting to teachers; it contains notes on such matters as the running of a laboratory, the care of apparatus and the uses of various appliances. The full course of volumetric analysis runs mostly on customary lines but includes a few novelties. The scheme of qualitative analysis, framed for mixtures containing one metal per group, exhibits no unusual features. It is in the preparations and in the many informative experiments illustrative of fundamental principles that one meets the author's skill and originality. Herein Mr. Davis displays a rare aptitude for modifying classical experiments and familiar techniques and devising new ones with economy of time and apparatus. His book can be confidently recommended.

## Joy and Verity, other Poems and a Poetic Drama

By Dr. Marie C. Stopes. Pp. 126. (London: Hogarth Press, 1952.) 6s. net.

THIS is the latest volume of a series of poetical works by Dr. Marie Stopes that began to appear in 1939. They are interesting in that love is treated passionately from a feminine point of view, and that the author does not hesitate to touch the themes of science with emotion and with imagination.

The outstanding poem in the volume is the title poem of forty-one stanzas, "Joy and Verity", which contains the distillation of a whole philosophy of life.

Personally, I enjoyed the poetic drama "Antigone Awakened". The matter is interesting—the theme of Sophocles' play with another ending. The spoken words of the actors and the chorus run easily and leave a feeling of freshness and of music.

Dr. Marie Stopes has always been a crusader. One gets more than a hint that the reforming spirit is now turning its attention to the breaking down of the inhibitions of scientists.

F. K.

# LIVERPOOL MEETING OF THE BRITISH ASSOCIATION

THIS year the British Association will meet in Liverpool for the sixth time. Between the first occasion in 1837 and the last in 1923, the alteration in the character of the meetings has reflected the change in the status and the role of the scientist no less than its proceedings have recorded the progress of a revolutionary age. In 1837, the president was William Cavendish, Earl of Burlington; but the address was read by Prof. Traill. Few records of the meeting survive beyond the girdings of the critics at what was thought to be the excessive degree of feasting and festivity. In 1854 the president was again a man of affairs, the Earl of Harrowby, and his address, carefully composed and resounding in phrase, was in part the conventional record of the Association's work during the year and in part an expression of his own views on the place of science in the community.

The later meetings, in 1870, 1896 and 1923, brought men of quite different outlook and reputation to the presidential chair. The first was T. H. Huxley, who delivered a remarkable address on the history of the rise and progress of a single biological doctrine which he termed biogenesis. In 1896 Lister spoke on Rontgen rays, on Pasteur's work on fermentation and then, for the first time before a public audience, about his own contribution to antisepsis. It is interesting to recall that Rutherford, who was president at the Liverpool meeting of 1923, attended his first meeting of the Association in 1896. It was natural that he should refer to it in the address which he delivered in 1923. "The visit to your city in 1896 was for me a memorable occasion, for it was here that I first attended a meeting of this Association, and here I read my first scientific paper. . . . The year 1896 has always seemed to me a memorable one for other reasons for in looking back with some sense of perspective we cannot fail to recognise that the last Liverpool meeting marked the beginning of what has been aptly termed the heroic age of Physical Science." It was peculiarly appropriate that Rutherford's presidential address should have been the first to be broadcast. It was a bold experiment on the part of the B.B.C., in the cultural no less than in the technical sense, and even in those days when cumbersome headphones had to be used and the crystal detector delicately adjusted, it seems to have been justified by its success. It was appropriate for another reason that the first such broadcast should be made from Liverpool, because the earliest public demonstration of signalling for short distances by electric waves had been given at the Association's meeting at Oxford in 1894 by Oliver Lodge, who was at that time professor of physics at University College, Liverpool.

Sir Edward Appleton will deliver his presidential address this year on "Science for its own Sake". In addition, Sir Edward will deliver a junior presidential address to student members, the title of which will be "Finding Things out with Radio and Rockets". This event will be an innovation, the idea of which came from the president himself. As at the Belfast meeting, special provision will be made for young people. Indeed, it is hoped that the active participation of young people on a larger scale than ever before will be a feature of the meeting. The local education authorities of Merseyside have expressed a lively interest in the project; and, with their co-operation, it is confidently expected that there will be a thousand student members at the meeting.

The handbook, "A Scientific Survey of Merseyside", has been prepared under the editorship of Prof. Wilfred Smith, and the majority of the articles have been written by his colleagues in the University. Those who know the care and time which have been given to the preparation of the handbook are confident that it will be an authoritative presentation which will merit a permanent place on the bookshelf as a work of reference.

The evening discourses will be given by Sir Harold Spencer Jones on "Continuous Creation" and by Mr. Eric Shipton on "Everest". The presidential addresses in the sections range from "The Development of Organic Chemistry since the Time of Liebig" by Prof. G. R. Clemo, to "Open and Repressed Monetary Inflation" by Prof. F. W. Paish. Not the least attractive should be the address in Section L by Mr. Robert Birley, headmaster of Eton College, under the provocative title, "Greek or Chemistry or Both ?".

The programme of general excursions is varied; they will range as far as Lake Vyrnwy in one direction and Lake Windermere in the other. Some of the sectional visits of more technical interest will be to the developing chain of light industries on either side of the Mersey. Further, after the meeting ends, there will be a special visit to the Isle of Man during September 9–12 at the invitation of the trustees of the Manx Museum.

There is no doubt of the welcome that Liverpool will give to the Association. The city values its long connexion with the British Association and the forthcoming meeting is anticipated with eagerness. The Norman Lockyer Lecture which was delivered by Sir Harold Spencer Jones in January was immensely successful. The Philharmonic Hall was filled and could have been filled again.

The University is especially proud to receive the Association in its own jubilee year, the celebration of which has just ended. Since the last meeting in Liverpool the accommodation of the University, for the smaller meetings, has been considerably extended, and the sections will have ample space within the precinct for most of their activities. The inaugural meeting will be held on September 2 in the splendid Philharmonic Hall belonging to the City, and will be preceded by a special congregation of the University for the conferment of honorary degrees.

The local committee for the meeting is confident that, under the presidency of Sir Edward Appleton, it will be an outstanding success; for it will bear the impress of its president's rare qualities of intellect and character.

# STANDARD SAMPLES OF ORGANIC SUBSTANCES FOR PHYSICO-CHEMICAL MEASUREMENTS

By D. AMBROSE

Chemical Research Laboratory, Teddington, Middlesex

FORMULATION of the fundamental laws of chemistry depended upon the recognition that properties of pure substances are constants which can be measured, and improvements in technique have required ever higher standards of purity in the samples used for these measurements, since the values obtained are frequently sensitive to the presence of small amounts of impurities; the use of impure samples is, in fact, one of the chief reasons for distrusting many of the older physical data acquired when chemists were building up the vast body of chemical knowledge, and in recent years a start has been made in accumulating a corresponding body of exact physical knowledge about pure chemical substances. To illustrate the need for this, melting and boiling points, the properties most frequently recorded to characterize substances, may be considered. A pioneer in the study of pure compounds has been Prof. J. Timmermans (of the International Bureau of Physico-Chemical Standards, Brussels), who in his books "Chemical Species" (1941) and "Physico-Chemical Constants of Pure Organic Compounds" (1950) has laid down the principles to be followed in a critical appraisal of published data, and collated what is satisfactory. Of the thousands of organic substances known, data for only about fifteen hundred are included in the publication last mentioned, and whereas the author states that boiling points should be known to 0·05° C. and freezing points to 0·1° C., in few cases is the range of values quoted from different investigators as small as this, even for common substances; for example, there is a range of 0·9° C. for the freezing point of methyl alcohol and 0·6° C. for the boiling point of acetic acid.

Precision is of value not only in fundamental science but also in applied science and industry, and a striking characteristic of modern chemical industry is the increasing stringency of specifications even for technical grades of material. Besides the economic reason that unwanted impurities are paid for as the desired material, pure materials tend to give purer products with greater reproducibility of properties and there is a necessity for purity (or at least a constant composition) in pharmaceutical products where traces of impurity may have great physiological effect. Some years ago, benzene of freezing point 5·4° C. was considered a first-grade material and anything with a higher melting point was almost unknown; but the true freezing point has been established as 5·53° C., and there is now a demand for commercial quantities of material approaching this purity for synthetic processes; a similar situation is arising with naphthalene, for which the present standard test is based on a melting point of 80·2° C., whereas the best value is now 80·27° C., corresponding to a change in the purity as determined by melting point of approximately 0·2 per cent.

This rise in the standard of commercial materials is due to the development of improved methods of analysis and process control which enable specifications to be drawn up and material to be produced nearer to the exact requirements of the user; and satisfactory analytical techniques depend upon the availability of pure reference samples. Such standard samples of inorganic materials have been available for many years; for example, the U.S. National Bureau of Standards has supplied standard alloys and pure metals for the past fifty years, and the system of standard analytical reagents is well established; but the use of organic standards is a recent development with which this article will deal.

## Use of Standard Samples

The uses of standard samples may be broadly divided into two categories. In the first (the primary establishment of standards) fall the determination with the highest attainable accuracy of physical properties of substances, and following those determinations, the intercomparison of measurements made in different laboratories and the transfer of measured quantities from one laboratory to another. For such purposes the user has generally had to purify and standardize the substance himself by applying suitable tests; but in the past ten years a remarkable example of co-operative work has been carried out by the American Petroleum Institute in conjunction with the U.S. National Bureau of Standards in preparing more than two hundred hydrocarbons in a state of the highest attainable purity for the systematic measurement of physical properties at various laboratories. To workers engaged in the field of pure organic compounds, this American contribution, which has been under the direction of Prof. F. D. Rossini, overshadows all others; but consideration that, even so, only about twenty compounds a year are being examined, shows what a stupendous task the collection of physico-chemical data is, and only those restricted fields of chemistry can be examined in which they are most needed.

The second category of uses for standard substances includes those in which the values of their properties as determined with the highest grade of instrument are used to calibrate and check the readings obtained with other instruments. Perhaps the most familiar example of this is the calibration of thermometers at the ice- and steam-points, and water is probably the most widely used standard substance, its triple point, latent heat of fusion, specific heat, and density being used as standards; other examples of the use of standard substances are provided by mercury for measurement of pressure, benzoic acid for calibrating bomb calorimeters and the whole series of secondary fixed points in thermometry. Besides direct calibration, it is useful to be able to check the results of a given method (and the operator) by applying it to a pure material the value for which is known accurately. A typical example occurred in the Chemical Research Laboratory, Teddington, when measurements of the refractive indices of a number of pyridine bases were unaccountably discordant. It was not until samples of pure *n*-pentane were also examined that the cell of the Pulfrich-type refractometer was found to be unsuitable for use with volatile liquids; when the cell had been modified, no further difficulties were experienced. The necessity for this would have been much harder to demonstrate had samples of materials known to be pure not been available.

Fresh interest in the use of standard substances, especially hydrocarbons, has been aroused by the widespread adoption of instrumental methods of analysis; in particular, the infra-red, ultra-violet and mass-spectrometers, the last of which has become a standard method of analysis for hydrocarbon gases in the still rapidly expanding petroleum and petrochemical industries. In general, analysis with these instruments is carried out by consideration of the pattern produced over a wide range of wave-length or mass number, and to this end a large number of spectrograms and cracking patterns of pure materials have been published, chiefly by the U.S. National Bureau of Standards, which do, in fact, enable analyses to be made. It is, however, more satisfactory to check the instrument-reading on a standard sample as well, since different instruments have their own characteristics, causing slight variations in the pattern produced. So marked is this with the mass-spectrometer that frequent recalibration with both pure materials and blends of known composition is needed, since the cracking pattern changes according to the condition of the electrodes. For these purposes it is impracticable for the user to make all the standards he needs, and in any event the use of standards of one origin eliminates a possible source of error when results obtained in different laboratories are to be compared. Requirements for standard samples are therefore still increasing, and in view of their importance the Commission for Physico-chemical Constants of the International Union of Chemistry has decided that one of its aims shall be the encouragement of their use.

## Purification

Generally, the preliminary stages in the preparation of material suitable for use as a standard must be carried out on a relatively large scale to permit the discard later of considerable portions containing impurities; and where possible it is often preferable to start with a commercial grade of the substance, or one closely related, which may be intensively purified to yield a small proportion of high-grade material, rather than to attempt a complete laboratory synthesis. This is the method used for the simpler coal tar and petroleum products such as benzene, toluene and the lower aliphatic hydrocarbons; but suitable raw material is often not available for more complicated substances. Laboratory methods of synthesis have then to be applied, often on an unusually large scale since it is desirable to make batches of about 1 kgm. and, for example, methods have now been developed for carrying out the Grignard reactions necessary in hydrocarbon syntheses on a 50-mole scale. In synthesis it is important that all materials used should be purified to avoid unnecessary impurities arising in the reaction, and further purification should be carried out at each of the intermediate stages even if the yield is thereby much reduced. The methods of purification are the usual ones of the organic chemist—distillation, crystallization, sublimation, adsorption, besides any suitable chemical reactions—but carried to the limit with consequent reduction of yield. In ordinary synthesis a balance has to be struck between the requirements for purity and for high yield; the second cannot be considered in producing material of the highest purity and, for example, in the production of 99·99 per cent benzene the material was crystallized about twenty-five times, while in distillation processes to produce the API-Research samples, often a middle cut of only 200–300 ml. was taken from 1 or 2 litres of already highly purified material.

## Purity: Its Definition and Determination

A pure substance may be considered as one all the molecules of which are identical, and it is customary to express purity in moles per cent, or the fraction of identical molecules in a given sample; but a difficulty arises over the definition of identical molecules because of the existence of isotopes. These cause definite variations in properties, but so minute that separation is rendered exceedingly difficult; not so minute, however, but that the exhaustive fractionation applied in purifying a sample may change the isotopic abundance ratios sufficiently to cause a measurable change in properties. Not only do the isotopic ratios change in the laboratory, but also their slight differences in thermodynamic and kinetic properties have led to natural fractionation so that the natural isotopic ratios are seldom constants. The Pure Metals Commission of the International Union of Pure and Applied Chemistry has resolved this difficulty by adopting two definitions of a pure metal, an 'ideal', and a 'practical'. A practical definition can only be considered in terms of the use to which the purified material is to be put, and the measurement by which the purity is determined. Any absolute definition which might specify the isotopic abundance ratios given by the International Commission of Atomic Weights would be ideal because they are not controllable in highly purified materials, and this applies throughout chemistry.

In setting up a chemical standard, the effect of the residual impurities must be considered; if negligible on the property to be measured, then those impurities may be ignored even though purity determined by other measurements is low. Of course, it will usually happen that a highly purified material will be suitable as a standard for many properties; but this is not always so, and sometimes the requirements for different properties are considerably different or even mutually exclusive. Hence the practical definition of a pure material as one the properties of which are unchanged by further purification must be qualified by a list of those properties, and each material considered separately before the statement of purity is generalized as indicating a standard for all properties. For example, the term 'spectroscopically pure' is used for solvents suitable for spectroscopy, but this merely means that the *cyclo*hexane or *iso*octane frequently used in ultra-violet work is free from impurities which absorb in that region, that is, olefines and aromatics, and they almost certainly contain other naphthenes and paraffins which do not affect their properties in the ultra-violet. Again, the lower pyridine bases all have refractive indices between 1·50 and 1·51, so in a sample of one of the picolines the effect on refractive index of a small proportion of another isomer is negligible compared with the similar proportion of water ($n = 1\cdot33$) which is absorbed on manipulation in air. On the other hand, in standardizing an instrument for the infra-red analysis of mixtures of these substances, it is the isomeric impurity which is of importance since the effect of water is easily allowed for.

Thanks to its special properties at low temperatures, the production of helium containing only $10^{-10}$ impurity has been claimed; but this is unique, and the present limit of impurity removal from organic compounds is usually about $10^{-4}$, a figure which is outside the sensitivity of most chemical methods of analysis applicable to organic materials, for the impurities present are often either homologues or isomers with almost identical chemical properties. Purity determination of organic compounds then depends upon physical measurements, and these should remain unvarying through whatever further process of purification the material is put, or from whatever source it is obtained, whether natural or synthetic. Any suitable physical property may be used, such as density, refractive index, boiling point or vapour pressure, that one being chosen for which so far as possible the substance has a value clearly distinct from its possible contaminants. Spectrometry is usually only a subsidiary method of checking pure compounds, since although sharply defined characteristics of the spectrograms sometimes enable certain impurities to be detected in trace quantities, there are often others present in considerable concentration which cannot be detected. Thus it is usually desirable to combine the results of several methods of testing. During the past ten years, however, methods of freezing-point determination have been developed which enable a quantitative estimate of purity to be made, and this precision and the relative simplicity of the determination have led to their widespread adoption in place of other methods; in fact, it is through this development that the supply of standardized materials has been put on a satisfactory basis. Melting-point determinations have long been used by the organic chemist as a check on purity, the assumption that all impurities lower the melting point being generally valid; but as customarily carried out, they are not precise, and freezing points are now much more accurately determined by plotting cooling curves. A sample of the liquid material is allowed to cool at a controlled rate in a suitable apparatus and its temperature measured precisely, in early methods with a platinum resistance thermometer but now more generally by some kind of automatic recording device, since it is not the absolute temperature but the change in temperature which is of importance. Most liquids must supercool before crystallization will occur, and skill is required to reduce the extent of supercooling to the minimum, by seeding at the right time, so as to produce as smooth a curve as possible. The rate of cooling is made very slow (perhaps 1° in 10 min. before crystallization begins), so that the complete cooling curve may take up to 1½ hr. to plot, and thermal equilibrium between solid and liquid is attained by stirring. In these conditions, when changes in temperature are measured to 0·001° C., a gradual depression is normally found as solidification takes place, from which the purity of the sample can be calculated, the limit of detectable impurity being about 0·01 mol. per cent. It may sometimes be preferable to work in reverse and plot a melting curve, for example, with substances which form glasses under conditions of slow cooling; the validity of the method depends upon the assumption that the pure material crystallizes from the melt, and where this is in doubt more complicated measurements of the specific heat in the melting region are required. These provide an even more sensitive test for impurities, but fortunately there is a large range of substances for which melting- or freezing-point determinations are adequate.

The value of freezing-point determinations is leading to their gradual adoption for routine testing besides the establishment of standards; but in ordinary practice purity is often established by comparing the properties of samples with a standard or the equivalent, the published values. This is actually a way of establishing impurity, but if a number of properties are of the correct value the purity may be considered as satisfactorily established.

## Supply of Standard Samples

The scale and type of work required for the preparation of pure compounds and measurement of their properties has resulted in a small number of laboratories specializing in it, of which the leading one has been the U.S. National Bureau of Standards in Washington. In conjunction with the American Petroleum Institute, about two hundred compounds, mostly hydrocarbons, are supplied in certified purity for use in calibrating spectrometers, and in addition the best samples are available on loan as the API-Research samples to investigators who wish to measure needed physical properties. Purities of these last normally lie between 99·7 and 99·95 mol. per cent, and those of the spectroscopic standard samples only a little lower. (This work has now been transferred to the Carnegie Institute of Technology, American Petroleum Institute Research Laboratory, Pittsburgh 13, Pennsylvania, U.S.A.) Certain hydrocarbons of slightly lower but still high and certified purity are also sold commercially in the United States, and when in 1949, in Great Britain, the Chemical Research Laboratory was asked by the Spectroscopic Panel of the Institute of Petroleum to start a scheme for the supply of standard samples of hydrocarbons, stocks of some of these were obtained for division into small samples, and some from the National Bureau of Standards. This scheme accorded well with the existing programme of the Purification and Measurements Section of the Organic Group of the Laboratory, which was already engaged on the purification of coal tar constituents with the view of measuring the following properties: vapour pressures, melting points, densities, refractive indices, ultraviolet and infra-red spectra, and, in conjunction with the National Physical Laboratory, heats of combustion and specific heats over a wide range of temperature; and the Laboratory now has a list of more than three dozen standard substances available for distribution, of which nearly one-half, including four coal-tar bases and five aromatic hydrocarbons, have been made in Britain. Various industrial firms have co-operated in the preparation of standards by providing suitable stock for purification, and one industrial research laboratory has given material of a purity sufficiently high for use as a standard; such gifts are welcome to augment the restricted resources available to the scheme, and acknowledgment of the source of the materials is made when samples are distributed. In selecting further compounds for inclusion in the standard samples programme, due regard is paid to the direction of the research programme approved by the Chemistry Research Board, and the needs, so far as we can ascertain them, of our customers; for the scheme to be of the greatest service it is essential that the Laboratory should aim at making those standards for which there is the widest demand. In the three years during which the scheme has been in existence, approximately eight hundred samples have been supplied to nearly forty different laboratories in industry and the universities.

This article, describing the background to one aspect of the work of the Chemical Research Laboratory, Department of Scientific and Industrial Research, Teddington, is published by permission of the Director.

# SOME CHEMICAL ASPECTS OF NORMAL GROWTH*

By Prof. F. BERGEL

Chester Beatty Research Institute, Royal Cancer Hospital, London, S.W.3

In his book "On Growth and Form"[1], where he describes the application of mathematical–physical methods to these two facets of biology, D'Arcy Thompson said that growth was a somewhat vague word for a very complex matter. Stimulated by this remark, a definition of growth and related phenomena was sought. After enumerating examples of mechanical and non-biological growth[2], including that of crystals[3] (illustrated by ciné films[4]), certain basic characteristics emerged, such as dependency on time, interdependency of growth, development and form, and irreversibility of increase in mass or volume. Then attention was turned to the cell as the unit of living matter. There biological growth consists of two kinds: by enlargement—auxetic growth; and by division—multiplicative growth. Further events may take place which are so closely connected with biological growth that they were by necessity included: fertilization, induction and differentiation, maintenance, regeneration and repair. Considering them in the light of elementary cytological knowledge, the following definition of biological growth phenomena was established: they are processes consisting of continuous synthesis of complex cellular constituents from assimilated material, leading through cell enlargement and multiplication to the mature organism, the size of which is determined by certain limiting factors and which often, by production of egg-cells undergoing fertilization by sperms, can perpetuate itself.

The next step was to seek out those problems which have yielded or would yield to a chemical or physicochemical treatment. Obviously energy is required to enable the cell not only to grow and to synthesize its constituents but also to maintain its high degree of orderliness. This energy is provided by light quanta in plants and by oxidation – reduction metabolism in animals. As randomness or disorder from a thermodynamic point of view corresponds to high entropy, and the opposite to low entropy, the carbohydrate and phosphate cycles, coupled to protein and fat metabolism and assisted by innumerable enzymes, generate energy in such form and manner that the remarkable stability of cells and their specific and identical processes—that is, a low state of entropy—are maintained.

Apart from oxygen and water, nutrients reach the cell and penetrate through the lipoproteinous membrane; on the whole, small molecules are taken up with greater ease and are then caught inside the cell by microsomes, mitochondria and the nuclei with their pre-existing large molecules, to be transformed into compounds required by the cell. It is assumed that the identity of specific sequential and steric properties of macromolecules so produced may be due to moulding processes on template molecules.

In contrast to some bacteria and fungi, the growth of which on synthetic media has been studied profitably, amoebæ do not grow on such media, and the development of tissue culture towards the use of synthetic nutrients, as investigated by Dr. C. Waymouth at the Chester Beatty Research Institute, is only slowly progressing. Although one knows at present relatively much about the metabolic events of energy production and the constitution of small molecular cell-constituents, it has taken a long time to sort out these low-molecular essentials with regard to their effect on growth, and it may take very much longer to recognize the possible existence and role of larger particles. The biochemical problems of cell division are not solved yet in detail. Whether the attainment of a critical ratio of size between cytoplasm and nucleus or between surface and volume, or whether with the enlargement of the cell the critical concentration of substances possibly of nucleic acid nature[5] will trigger off mitosis, or whether a number of factors have to come together to this end, the last and true physical or chemical cause of cell cleavage is still largely unknown. Even greater complexities meet the student of the biochemical phenomena of fertilization, induction and cyto- and histo-differentiation. Shifting of nucleic acid gradients[6], mutual influences of the first cells derived from the fertilized egg[7], polarities in the cells and defined evocator substances[8] have been suggested, defended and sometimes abandoned. Particularly, the story of the evocators is in some respects reminiscent of that of the carcinogenic substances, because in both groups a great number of dissimilar substances, maybe by different modes of action, produce the same terminal effects—morphogenesis and malignancy, respectively. Claims have been put forward in favour of embryonic growth factors being replaceable by proteose–polynucleotide combinations[9]. It is not impossible that the disappearance of such specific factors, together with the cessation of sensitivity of most tissues to the action of growth regulators of low molecular weight, may contribute to the slowing-down and final arrest of growth in the adult organism. In addition, mechanical and thermodynamic conditions could lead as well to this phenomenon of limitation of growth, especially if energy required for maintenance and repair reaches equality with that produced by metabolic processes and thus, roughly speaking, loss of heat can be just balanced by intake of food.

## Building Units

It is recognized that, apart from medium-sized and smaller units such as co-enzymes, some hormones, energy carriers and other functional substances, mostly large molecules, are present in cells and participate in their structure, growth and development. On the other hand, still larger particles such as microsomes, mitochondria, chromosomes, nuclei and plasmagenes form the subject of recent investigations which will not be included in this review. Among the macromolecules, proteins and nucleotides seem to play a major part in cellular events. Dr. T. S. Work[10] has, in some recent lectures, described the biosynthesis of proteins. It remains, therefore, to consider the nucleic acid problem and to give some attention to configurational questions with regard to proteins and to the relationship between the synthesis of these two macro-structures so that some of the points touched upon above may become clearer. In Table I the connexions between pyrimidines, purines, nucleosides, nucleotides, and finally ribo- (RNA) and deoxyribo- (DNA) nucleic acids are presented. The biosynthesis of the bases and the sugars have been progressively studied during recent years[11]. The work of the Cambridge school has largely contributed to the final elucidation of nucleosides[12] and, together with the results obtained by American workers, to that of the nucleic acids themselves as poly-3′ : 5′-phosphates.

---

* Synopsis of three lectures given at the Pharmacology Department, University College, London, during January–February 1953.

The most stimulating analysis by Brown and Todd[13] of accumulated evidence with the important hypothesis of 2′ : 3′-*cyclo*phosphates as intermediates of breakdown of ribonucleic acid has led to the isolation by Markham and Smith[14] of such compounds from controlled hydrolysis of ribonucleic acid. Table 1 also traces the interconnexions of nucleic catabolism which, so it is believed, following work by Haddow and Timmis[15] on substances producing kidney hypertrophy, is as important for normal growth as their anabolism or synthesis. A study of the enzyme systems responsible for the last stage of the degradation, particularly of xanthine oxidase and its inhibitors, has been commenced in this connexion[16].

From the configurational and physico-chemical point of view, especially according to recent work by Butler *et al.*, Ambrose, and Alexander *et al.*[17], one is more inclined to favour the Furberg variation of Astbury's closely packed column of deoxyribonucleic acid with its bases alternating on both sides of a zig-zag phosphate-sugar chain. This arrangement produces a practical distance of about 7 A. between the acid groups of the polyelectrolyte if the macromolecule is moderately stretched. How this fits in with the newest rope idea of Pauling and Corey[18] for nucleic acid will have to be seen, particularly as nucleic acids *in vitro* and *in vivo* may show differences in steric properties. However, the recent views on structure and physico-chemical properties of proteins[19,20] would fit in well with nucleic acids having, apart from branching, only a statistical but not a factual distance of 3·4 A. between neighbouring acidic groups like the proteins in β-*trans*-configuration between proximate side-chains. There are some steric questions in the protein field to which there exist more than one answer. Proteins can also occur in a contracted α-form, and Pauling and Corey[19] have suggested for this an α-helix arrangement with side-chains at right angles to the axis of the spiral and hydrogen bonding across turns. More recently these American authors[21] expressed themselves in favour of a polypeptide chain helix itself pursuing a helical course ; several of these would form rope-like strands similar to those mentioned above for nucleic acids. As nearly all functional proteins belong to the group of globular proteins, it is important to know something about their history of formation. According to Ambrose[22], they originate in a kind of β-α-pathway (to which reference will be made below) to coil up either as a result of interaction of reactive side-chains or, following Pauling's antigen–antibody hypothesis, around or below another protein molecule of a certain shape. As far as their primary synthesis in β or α form is concerned, this brings one face to face with the problem of identical reproduction of configurational and sequential features of proteins in the cell. Gale's recent work[23] on *Staphylococcus aureus* and the selective inhibitory action of certain antibiotics on the protein and nucleic acid synthesis of these bacteria supports the views expressed before in various quarters that nucleic acid and protein syntheses are interconnected. So far it has not been established in what manner. *In vivo* polynucleotides are always combined with proteinous substances such as histones, protamines or proteins. If one takes into consideration what was said above, namely, that *in vitro* observations may not apply to the conditions in the cell, the speculation that nucleic acids act as templates, or at least as part of templates for their own synthesis and that of proteins, is an attractive one ; but no final proof is as yet available. Recently, Dounce[24] has published some ideas on this subject, the first step of the biosynthesis consisting of an

action of adenosine triphosphate on nucleic acid, producing a hypothetical diphosphonucleic acid from which, with amino-acids, polypeptide-chains and with mono-nucleotides, polynucleotides are supposed to emerge. If one pays more attention to experimental evidence and takes into consideration the following points—the 7 A. distance of the side-chains in the β-*trans* form of the initial peptide chain and of the P—OH-groups in the Furberg nucleic acid model, the relative lack of specificity of nucleic acids in directing the sequence of amino-acids, and a hypothesis put forward by Haurowitz[24]—one can arrive at another speculation. It amounts to this: that a pre-existing protein is held in position by the nucleic acid which is acting mainly as a 'backbone', and that the protein functions as the actual template on to which amino-acids 'crystallize' out each on identical spots in a crystal growth fashion. Possibly under the influence of further enzymatically acting proteins, a peptide chain is formed. This new peptide chain will leave the surface of the template and overcome its attracting forces if, after Ambrose[25], one assumes that the intramolecular attraction of N—H and C=O groups to form hydrogen bonds could pull the amino-acid side-chain away from the template. Now, the new protein folds up into a globular form as indicated above. There are, of course, other views, such as that expressed by Work[19] on transpeptidation. It is clear that all this needs more solid experimental evidence in the future.

## Regulators

It was mentioned before that smaller molecules play their part in cellular events, and some exert considerable influence on growth phenomena. These can be loosely grouped together under the name of growth regulators, a term which, even when restricted to those substances occurring in living organisms, still comprises substances of great chemical diversity. From Table 2 it can be seen that a variety of sub-groups is involved.

Some of these substances are synthesized by the organism; others are ingested with food. Some are involved in energy-producing metabolism; others have specific anabolic or catabolic functions or form the right building-units for the synthetic processes of the cells. A considerable number have similar or identical functions in lower and higher organisms due to the same biochemical arrangements. However, the auxins or plant growth regulators seem to exercise their promoting and controlling effects solely in higher plants—for example, the group derived metabolically from tryptophane, indolylacetic acid and indolyl acetonitrile[26]. The mode of action of these and a great number of synthetic analogues has not so far been established with certainty, although attempts at solving the mystery of their stimulatory and inhibitory effects have been made[27]. Such attempts have promoted work in the field of abnormal growth, for example, that on urethane by Haddow and Sexton[28]. It is especially the B-group of vitamins which have proved to be of equal value to micro-organisms and animals, a matter which has been recently discussed, among other things, on the occasion of a meeting of the Nutrition Society[29].

Apart from those identified with bios factors, and with essential co-enzymes, a super-growth factor *T* was claimed by Goetsch[30] to have been isolated from torula yeast. Later[31], it was shown that it consisted of a mixture of folic acid, folinic acid, *Lactobacillus bulgaricus* factor, deoxyribosides and a small amount of vitamin $B_{12}$. The last-named and folic acid and its derivatives have aroused particular interest, as they may be involved in nucleic acid synthesis and thus in cell division[32]. While it is not clear whether they participate in these events in the form of co-enzymes, the situation with pantothenic acid is now clarified. The formula of co-enzyme A has recently been published[33], and its role in biosyntheses, such as those of citrate, fatty acids, sterols and phospholipids, established. Even a peptide, glutathione, has now been recognized as a co-enzyme by Racker and

Krimsky[34]; it is involved in the oxidative phosphorylation of phosphoglyceraldehyde. Whether strepogenine, another peptide-growth factor, and certain amino-acids which in tadpoles, according to Gudernatsch and Hoffmann[35], either support growth or just maintenance or morphogenesis, act as regulators or are used as building units, is unknown. Of course, all functional proteins, whether as apoenzymes or as proteinous enzymes, operate directly or indirectly in processes of growth and development. The same applies to pituitary hormones such as growth, adrenocorticotropic (ACTH) and gonadotropic hormones, the first having an immediate effect on overall growth, and the last two by controlling other endocrine substances. It is not unlikely that some of the effects are achieved by influencing the level of protein synthesis, as put forward by F. G. Young[36] and more recently by Cornforth and Long[37], and as confirmed with regard to the growth-retarding effects of corticosteroids in this manner by Clark[38]. The action of androgens and œstrogens on sex organs, apart from their luteinizing and follicle-stimulating activity, turns out to be more and more that of balancing regulators[39], which links the field of normal with that of abnormal growth. There are many chemical problems still unsolved with regard to normal growth and development, and a long list could be prepared which should clearly emerge from this very condensed summary.

# METAL PHYSICS WORK OF THE DIVISION OF TRIBOPHYSICS, C.S.I.R.O.

By Dr. W. BOAS

Chief, Division of Tribophysics, Commonwealth Scientific and Industrial Research Organization, University of Melbourne

THE Division of Tribophysics of the Commonwealth Scientific and Industrial Research Organization, which began life thirteen years ago as a group studying war-time problems of friction and lubrication, has just moved into its new home in the grounds of the University of Melbourne. The laboratory, a brick building of three stories and a basement, occupies a position in the heart of the University. That a university, already hard-pressed for space, should be willing to give up such an excellent site to a laboratory of the Organization is a tribute to the friendly spirit of co-operation that has developed between the Organization and the universities in Australia.

The work of the Division has broadened from its strictly utilitarian beginnings and now includes a general study of the physics and physical chemistry of solids, particularly metals, and of solid surfaces. The metal physics work of the Division is mainly concerned with the study of the mechanisms of plastic deformation and phase changes, the two main phenomena involved in changing the properties of metals. This work is aimed at a better understanding of the properties and behaviour of metals and alloys, so that the optimum conditions of a material for its various applications can be stated, or alloys developed for new applications.

## Thermal Fatigue

One of the first investigations originated from the observation that lead-base bearings withstood repeated heating and cooling as an engine was started and stopped, whereas tin-base bearings showed cracking and surface damage. This difference in behaviour was traced back to the crystal structures of the pure metals lead and tin. The thermal expansion of the cubic metal lead is the same in all crystallographic directions, whereas the tetragonal tin has a coefficient of thermal expansion in the direction of the tetragonal axis twice that in any direction at right angles to this axis. In tin, at the boundaries between crystals of different orientations, free thermal expansion is hindered, and therefore, when the temperature changes, stresses are set up which are large enough to cause plastic deformation and even cracking. In consequence of this effect, polycrystalline specimens of those non-cubic metals which have a large degree of anisotropy of thermal expansion cannot be obtained in a completely strain-free condition.

As the stresses originate at the grain boundaries, they are not uniform in the crystals, and hence the deformation of the crystals is inhomogeneous. Such inhomogeneous stresses have an important effect on the plastic behaviour and failure of metals, and they may arise from various sources.

## Inhomogeneity of Plastic Deformation

An obvious cause of macroscopic inhomogeneity is the friction between forming-tool and metal in industrial methods of deformation, such as drawing and rolling. The inhomogeneity of deformation on a microscopic scale must affect the mechanical properties of polycrystalline metals. If the crystals in an aggregate were independent of each other, the properties of the aggregate would be fully determined by the properties of the crystals and could be calculated by averaging the values of the properties of crystals of all orientations occurring in the aggregate. However, if the aggregate is subjected to stresses, the interaction between the crystals becomes important, as the boundary between any two crystals cannot at the same time suffer two independent deformations.

It has been shown experimentally that, in an aggregate, there are wide differences in the amounts of deformation and work-hardening from crystal to crystal. Moreover, the deformation is not uniform even within any one crystal since it is influenced by that of its neighbours. As a boundary is approached, the deformation becomes larger than at the centre if the average deformation of the neighbour is larger, and in the neighbour the deformation is less near this boundary than at its centre. Thus, a strong crystal supports its neighbours whereas a crystal with a low elastic limit has a weakening effect.

Most of these results were obtained from observations on the surface of the specimen. Special etching techniques, however, made it possible to investigate the behaviour of crystals which, during deformation, were in the interior—that is, surrounded on all sides by other crystals. These crystals behaved in the same way as those in the surface. This was confirmed by a study of duplex alloys, in which the inhomogeneity is due to the different compositions and structures of the crystals of the two phases rather than to their anisotropy.

As it is thus clear that the inhomogeneity of deformation is not a surface effect but occurs throughout the volume of the specimen and is inherent in all crystal aggregates, it has to be taken into account in any theory in which the properties of polycrystalline aggregates are calculated from those of the single crystals.

## Recrystallization

One of the methods used in arriving at these results was to observe the recrystallization behaviour of metals and alloys. For this a knowledge of the mode of growth of the new crystals during recrystallization is desirable.

In order to observe the progress of recrystallization continuously, a method was developed using polarized light reflected from the surface of non-cubic metals where the plane of polarization is rotated by an amount depending on the orientation of the crystal. Observations made on zinc show that the growth of a nucleus during recrystallization is very irregular; its extent varies with direction and from point to point in a crystal, and it can stop altogether for relatively long periods.

The observation of irregularity of growth throws doubt on conclusions drawn previously from measurements of the rate of nucleation during the recrystallization of fine-grained specimens. By counting the number of new grains which appeared after various periods of annealing, the apparent nucleation-rate was found to increase with the duration of annealing, and, assuming a constant rate of growth during the period from nucleation to observation, the true rate of nucleation was said to increase too. This conclusion presents a puzzle from the theoretical point of view and cannot be sustained in view of the observed erratic growth of the nuclei. The period during which a growing nucleus remains too small to be observable will be extremely variable, and, for a constant and even slowly decreasing nucleation-rate, the number of unobserved nuclei will increase with time. A certain fraction of these will grow to an observable size in successive units of time, and hence the apparent rate of nucleation will increase though the true nucleation-rate may not.

## Mechanism of Plastic Deformation

The plastic deformation of metals occurs mainly by slip within the crystals, and it is now generally assumed that slip takes place through the motion of dislocations. Although the basic idea of the theory —that is, that slip is a localized process—is well founded on experimental results, several rather artificial assumptions have to be made to explain some of the experimental observations. Further, much of the earlier published work used unsuitable materials and methods. Hence, an experimental attack on the problems of slip and work-hardening of metals is being made by measuring the changes produced by deformation in internal energy, X-ray interferences and electrical resistivity.

Previous investigations had shown that about 10 per cent of the work done on a specimen during plastic deformation is stored, whereas the major part is dissipated as heat. The stored energy is liberated on annealing and can be determined as the (small) difference in specific heats of undeformed and deformed specimens with an accuracy of about 20–30 per cent.

Using a differential method, in which deformed and annealed specimens of equal weight are heated simultaneously in the one enclosure, an accuracy of ± 5 per cent is obtained. The difference in power supplied to the specimens, in order to maintain their temperature difference within 1/20 deg. C., is measured continuously with a specially designed differential wattmeter. The curve showing the release of the stored energy as a function of temperature is thus obtained directly.

Results obtained for specimens of electrolytic copper deformed in torsion show that the stored energy increases with deformation in a similar way to the torque required to produce the deformation. Small amounts of some impurities appear to be responsible for large differences both in the recrystallization temperatures and in the shapes of the curve of released energy against temperature, and may also change markedly the total stored energy. With nickel, about 40 per cent of the stored energy is released in a temperature-range in which the electrical resistivity reverts almost to the lower value of the undeformed metal, whereas removal of both work-hardening and broadening of X-ray diffraction lines occurs at a temperature about 300 deg. C. higher. These results support the suggestion that vacancies generated during plastic deformation are the main cause of the accompanying increase in electrical resistivity.

The electrical resistivity of several metals and alloys was measured at temperatures in the range from − 183 to + 100° C. after various degrees of deformation by wire-drawing which was carried out in the same temperature-range. The results showed that the behaviour of some metals, notably of tungsten and molybdenum, which formerly had been considered anomalous because of a large relative increase in resistivity, can be explained if the high recrystallization temperatures of these metals are taken into account. Another observation was that, on wire-drawing and rolling, the electrical resistivity of some cubic metals becomes anisotropic. An analysis of the results indicated that the increase in electrical resistivity with deformation may not be caused entirely by dislocations and lattice vacancies, but that stacking faults in face-centred cubic crystals may also play an important part.

## Mechanism of Phase Changes

There are two ways in which a transformation in the solid state may occur. First, the atoms may be rearranged to form a crystal of the new structure which has the same external shape as the original crystal. Such transformations involve nucleation and growth of nuclei, and depend on thermally activated diffusion. Secondly, the rearrangement of the atoms may occur in such a way that each atom has the same neighbours in the new structure as it had in the old. This leads to a change in external shape which produces relief effects on polished surfaces. These phase changes occur extremely rapidly, even at temperatures where the rate of diffusion is very small, and proceed only during cooling and not isothermally to any appreciable extent.

As for the mechanism of thermally activated diffusion, it appears that the movement of atoms is connected with that of lattice holes. The development of the theory may be assisted by investigating the effect of atomic packing on the rate of diffusion, and for this reason the rate of self-diffusion was measured in various directions in tin crystals, as these show anisotropy of the diffusion-rate and no chemical complications occur, since only one type of atom is involved. It was found that the activation energy for diffusion along the tetragonal axis was about one and a half times that for diffusion in any direction at right angles to it, and the geometrical factor was about forty times larger for the tetragonal axis. However, it has not been possible to correlate the activation energy with such other physical properties as are mainly determined by the energy with which the atom is bound to its equilibrium position in the structure.

The investigation of 'diffusionless' transformations is particularly attractive, as it is hoped that from their features the movement of the atoms during the transformation may be deduced. An attempt is now being made to determine the atomic movements in transformations which produce changes in external shape, although they occur by thermal diffusion. The fact that the orientation of the new crystals is related to that of the matrix suggests that the mechanisms by which nucleation-growth and diffusionless transformations occur may not be as fundamentally different as was previously thought.

The work described in this paper is the result of close collaboration of a number of workers, and it is difficult to disentangle the individual contributions. For this reason no reference has been made to particular publications.

# OBITUARIES

## Dr. R. W. Gurney

Dr. Ronald Gurney, who died at his home in New York on April 15 at the age of fifty-four, was born in Cheltenham and was educated at Cheltenham College. After service in the Gloucestershire Regiment in the First World War, he went to Cambridge, where he was an undergraduate at Trinity Hall. He began his career as a scientist at the Cavendish Laboratory under Rutherford, where he carried out experiments on the ionization by fast particles and published a number of papers on this subject. It was during a visit to the United States, however, that he made in 1929 the first of those striking incursions into theoretical physics by which he will be mainly remembered; in collaboration with E. U. Condon, he gave the first correct explanation of α-decay in terms of wave mechanics, anticipating by several months the similar but more detailed treatment of Gamow. From this time onwards he became a theorist; after some years at Manchester with W. L. Bragg, he came to Bristol in 1935 and worked with me. We produced jointly the book "Electronic Processes in Ionic Crystals", and also a theory of the nature of the photographic latent image, much—if not all—of which has stood the test of time. In addition, he worked on the theory of liquids, and in Manchester and Bristol he laid the foundation of his future work on ions in solution.

In 1941 Gurney went to the United States and worked first at the Ballistic Research Laboratories of the Aberdeen Proving Ground, then at the Argonne Atomic Laboratory, at the Johns Hopkins University, and finally at the University of Maryland.

Gurney's publications include the books "Elementary Quantum Mechanics" (1934), "Ions in Solution" (1936), "Introduction to Statistical Mechanics" (1949) and "Ionic Processes in Solution", recently published by the McGraw-Hill Book Co. It was typical of him that, though he could use mathematics as well as another, he never trusted it; no theory was a theory to him until he could grasp it intuitively and, above all, draw diagrams of it. In this he was among theorists perhaps the truest representative of Rutherford's school, and of the British tradition. Wherever Gurney went—and not least at Bristol—he contributed to the work of the place a capacity to see things clearly, graphically, and in their essentials. He was a man with whom it was a privilege to work, and from whose unique qualities of mind and character his collaborators could learn much.

In 1950 Gurney had a stroke, and although he recovered well he was advised not to incur the strain of regular lecturing. During his last three years he was able, with the constant help of his wife Mrs. Natalie Gurney, to devote himself to his last book, which has appeared since his death. His many friends and colleagues will look forward to another example of his unique ability to make the complex simple and to get to the heart of things.

N. F. Mott

---

## Dr. C. E. M. Joad

Dr. C. E. M. Joad was reader in philosophy in the University of London and head of the Department of Philosophy, Birkbeck College. By his recent death, philosophy has lost one of its most lucid expositors and teachers. A list of his writings shows how wide were his interests. He was not satisfied until he had studied the philosophical bearings of modern developments in science, in the theory and practice of politics and in changes in manners and morals. When his thinking led to a major change in his personal beliefs, he explained his reasons and his readers had the full benefit of his experience. He thought aloud and on paper, and he dealt with no problem which he did not illuminate. His favourite saying was that if anything could be said, it could be said clearly, and certainly he never said or wrote anything vague or obscure. This may sometimes have led him to over-simplify some problems and to do less than justice to the more subtle points, but his readers have nothing to unlearn; they are beguiled into a deeper study of the problems set out in such a clear and stimulating way in Dr. Joad's various guides to philosophy. These books are models of what an introduction to a difficult subject should be.

In his own philosophical thinking, Dr. Joad was in the unfortunate position of having outgrown the Idealistic teaching of his Oxford days, and of being out of sympathy with the modern school, though he never ceased to admire the brilliance of its leading thinkers. He thought he had found the key to much that is unsatisfactory in modern thinking and conduct in the 'dropping of the object' in our judgments of value, a view that is presented brilliantly and provocatively in his study of decadence. He was happiest in the writings of the ancients, and he had the faculty of presenting their problems as though they were fresh and contemporary. To hear him lecture on the Nicomachean ethics of Aristotle was an unforgettable experience.

Dr. Joad esteemed it a privilege, and the source of his greatest satisfaction, to have been able to guide the thinking of so many young people. Thousands of students, inside and outside university walls, owe to him the discovery that it is exciting to think and a duty to think clearly. He will be missed far more than he would have expected, for he was essentially a humble man.

## Mr. W. Birtwistle

Mr. W. Birtwistle died at Skibbereen, Co. Cork, on March 4, within two days of his sixty-third birthday. Educated at Blackburn Grammar School, he served in the First World War, and in 1920–24 studied oceanography and fisheries under the late Prof. James Johnstone in the University of Liverpool. In 1925 he took up duty as fisheries economist, in charge of the Fisheries Department, Straits Settlements, and Federated Malay States, later assuming the title of director of fisheries. He retired in 1945.

Mr. Birtwistle was a pioneer of fishery development in the Far East, with especial attention to the introduction of power-driven fishing craft, and the cultivation of fish in rice fields. These and many other developments he sponsored were published in the annual reports of the Malayan Fisheries Department. He could foresee future developments in Asia, and made provision for the advanced training of Asian staff in the late 1930's. The wisdom of this has already been shown in the good work done by these men. He was highly respected by the fishermen, and on his death tributes were paid by men of all nationalities in Malaya.

# NEWS and VIEWS

## Sedleian Chair of Natural Philosophy at Oxford: Prof. Sydney Chapman, F.R.S.

The retirement of Prof. Sydney Chapman from the Sedleian chair of natural philosophy at Oxford has just been announced. Prof. Chapman reaches the age limit after occupying this chair since 1946. Before going to Oxford (see *Nature*, 157, 155; 1946) Prof. Chapman had been at the Imperial College of Science and Technology, London, for no less than twenty-two years. Fortunately, his departure from Oxford is not going to hinder his interests in geomagnetism and the upper atmosphere, for he is to continue as professor of geophysics at the University of Alaska, an appointment which he has held since 1951 in addition to his work at Oxford. His many friends all over the world will be glad to think that in this way he will be able to increase the very considerable debt that is already owed to him by workers in those fields which are peculiarly his own, and where his influence will remain for many years to come.

## Prof. George Temple, F.R.S.

The appointment has been announced of Prof. George Temple to succeed Prof. Chapman. Like his predecessor, Prof. Temple has wide interests. Educated at Birkbeck College, London, and Trinity College, Cambridge, he held teaching posts at Birkbeck College (1922–24), at the City and Guilds College (1924–28) and at the Royal College of Science (1928–30) before being appointed to the chair of applied mathematics at King's College, London, a position which he has held with great success for the past twenty-one years. Prof. Temple was elected a Fellow of the Royal Society in 1943. His earlier researches were in mathematical physics and relativity, to be followed by a vigorous and highly productive application to the quantum theory when this was developed in the late 1920's. A text-book on Rayleigh's principle and another on the general principles of the quantum theory bear evidence of these interests. More recently he has been occupied with problems in aerodynamics, and has become one of the leading theoretical experts in the subject in Britain. He will be most welcome at Oxford, where his wide knowledge of mathematics will help to supplement that of his colleagues, and where his considerable administrative experience and easy charm of manner will prove most valuable.

## Letters to Sir William Siemens

A collection of more than two hundred and fifty letters written by men of science, statesmen, artists and other notable personalities to Sir William Siemens, the distinguished scientist and engineer of the nineteenth century, has recently been acquired from a relative of Lady Siemens by Sir George Nelson, chairman and managing director of the English Electric Co., Ltd. These letters, arranged chronologically, have been mounted in two special volumes with the printed text on facing pages, together with a short biography of Siemens written by W. H. Kennett, short notes on the authors of the letters and an index. A third volume, made up of the printed copies of the letters, the biography, etc., and facsimile copies of twenty-two of the letters (which to the inexpert eye are scarcely distinguishable from the originals), was presented by Sir George on May 14 to the Institution of Electrical Engineers. In addition, a thousand copies of a general edition of the letters have been printed and will be presented to universities, libraries and engineering societies. The letters are very mixed in content and personality of author, but they serve a useful purpose in revealing the wide interests of Siemens and in reflecting the manners of the times in which he lived. The letters written by men of science form a minority, but they are a notable array; his correspondents included Airy, Bessemer, Crookes, Darwin, Dawson, Faraday, Fowler, Hooker, Helmholtz, Huxley, Kelvin, Lockyer, Maxwell, Rankine, Rayleigh, Roscoe, Tyndall, Wheatstone and Whitworth. That by Sir Norman Lockyer, the astronomer and founder-editor of *Nature*, deals with a previous statement made by him that there is no oxygen to be detected spectroscopically in the sun's chromosphere. The letters range in date from one of a number by Faraday in 1862 to one by Lady Kelvin in 1902 deploring the death of Queen Victoria and looking forward, with very mixed feelings, to the Coronation of Edward VII.

## Committee on the Effects of Synthetic Detergents

The Minister of Housing and Local Government, Mr. Harold Macmillan, has stated that, after consulting the Secretary of State for Scotland and the Minister of Health, he has appointed a committee with the following terms of reference: "to examine and report on the effects of the increasing use of synthetic detergents and to make any recommendations that seem desirable with particular reference to the functioning of the public health services". The committee is constituted as follows: Sir Harry Jephcott, chairman and managing director of Glaxo Laboratories, Ltd. (chairman); Dr. N. R. Beattie, principal medical officer, Ministry of Health; C. E. Boast, borough engineer and surveyor, County Borough of Croydon; Prof. J. C. Cruickshank, professor of bacteriology as applied to hygiene, London School of Hygiene and Tropical Medicine; G. H. W. Cullinan, general manager, Shell Chemicals, Ltd.; Lt.-Col. E. F. W. Mackenzie, director of water examination, Metropolitan Water Board; G. MacRobbie, assistant secretary, Department of Health for Scotland; F. D. Morrell, director, Unilever, Ltd., London; Dr. J. R. Nicholls, deputy government chemist; F. T. K. Pentelow, chief inspector of salmon and freshwater fisheries, Ministry of Agriculture and Fisheries; Dr. B. A. Southgate, director, Water Pollution Research Laboratory, Department of Scientific and Industrial Research; H. Symon, under-secretary, Ministry of Housing and Local Government; W. L. Thomas, chief chemist and technical director, Woolcombers, Ltd., Bradford; C. B. Townend, chief engineer, main drainage, Middlesex County Council; R. Craig Wood, managing director, Thomas Hedley and Co., Ltd., Newcastle upon Tyne. *Technical Officers:* Dr. E. A. B. Birse, chief inspector of alkali works and rivers pollution, Department of Health for Scotland; Lt.-Col. F. G. Hill, adviser on sewerage and sewage disposal, Ministry of Housing and Local Government; Dr. A. Key, senior chemical inspector, Ministry of Housing and Local Government. The secretary to the committee is Mr. A. R. Isserlis, Ministry of Housing and Local Government.

## Geological Society of Australia

The recently constituted Geological Society of Australia grew from groups of geologists who have met more or less informally during the past few years at various centres in the Commonwealth. The Society has been organized on a Federal basis with State divisions, local branches at appropriate centres, and a Federal Council governing the whole. While membership is being established in the several States (including the Federal Territories), the Society is functioning under a Provisional Council with Prof. E. S. Hills as chairman. Formal elections are to be held in June. The first publication of the Society, No. 1 of the *News Bulletin*, has appeared (March 1953) and plans for the issue of a *Journal* are well advanced. No papers will appear in the *News Bulletin*, the function of which is intended to be the welding of closer personal bonds between Australian geologists. The first issue is of lively interest and contains many items of personal news besides summaries of work in progress. The New South Wales Division, for example, has reports from the University of Sydney, New England University College, the Geological Survey, a number of museums and public authorities, and various mining companies in the Broken Hill district.

Noteworthy news items include the following. A late Pre-Cambrian tillite has been discovered in the north of Western Australia. The heat-flow in Tasmania is being measured by the Geophysics Department of the National University. Prof. S. W. Carey is spending a sabbatical year developing his views on continental drift. Prof. E. S. Hills is completing a study of Upper Devonian cauldron subsidences in Victoria including one fifteen miles across. Some of the members of Prof. C. E. Marshall's staff at Sydney are engaged in investigating the geology of the Solomon Islands and parts of Papua; a recent graduate has been "well-sitting" (*sic*) with an oil company; and a teaching fellow "has resigned to enter the church". Altogether the *Bulletin* should add considerably to the gaiety of Australian—and not only Australian—geologists. But it closes on a more sombre note with an obituary notice of the late Prof. E. W. Skeats, who died in January at the age of seventy-eight. Judging by the response of Australian geologists to the demands and privileges of their new Society, success would seem to be well assured. The first issue of the forthcoming *Journal* will be eagerly awaited.

## The Spirit of Applied Mathematics

Under the title of "The Spirit of Applied Mathematics", Prof. C. A. Coulson gave his inaugural lecture on October 28, 1952, as Rouse Ball professor of applied mathematics in the University of Oxford, and the text of the lecture has now been published (pp. 24. Oxford: Clarendon Press; London: Oxford University Press, 1953. 2*s*. 6*d*. net). After tributes to the founder of the chair, to his own predecessor, Prof. E. A. Milne, and to the mathematician – physicist – biologist, D. E. Lea, Prof. Coulson said that applied mathematics is, more frequently than not, misunderstood. Even its name is against it, as it suggests that it is a mental rag-bag in which one can rummage to find a bit of unused mathematics applicable to the latest discovery in experimental physics. But really the glory of applied mathematics, he continued, is not in such applications but in the creation of concepts, an intellectual adventure which combines creative imagination and canons of beauty to give insight into the nature of the world. Lying between pure mathematics and the experimental sciences of physics and chemistry, the results of which remain substantially unaltered, applied mathematics has the surprising difference that it is liable to rapid changes, and its progress consists of the creative process of finding a new set of concepts to transcend the old. The value of such concepts does not depend on their permanence, and some of the best, for example, Bohr's theory of the atom, did not survive unchanged for more than a generation. The essentials, said Prof. Coulson, are the joy, passion and creative impulse, the search for beauty, simplicity and integrity in structure and form, set in an environment partly dependent on, and yet in its deepest sense independent of, experiment and pure mathematics.

## Sea Foam

SOMETIMES, after heavy and prolonged onshore storms, great masses of foam are drifted in from the sea on to local rocks and beaches. A curious feature of these lather-like masses is the way in which they persist for relatively long periods even when blown about by the wind. Ordinary lathers soon revert to their former unlathered state; but sea foams may persist for a day or more when the weather continues moist and stormy and no sun shines. It is possible that the foam is 'held' by the presence of some protein material, and Miss E. M. Moore suggests that this protein material might be found in the alginate products of sea-weeds. This, however, does not explain how the surface tension of sea-water could be so lowered that the whipping action of storm waves could create a frothy mass (*Aust. Mus. Mag.*, 10, 11; 1952). A likely explanation of the phenomenon is that, during storms, large numbers of planktonic organisms are destroyed and broken up because of the battering they receive in choppy seas. The surface tension-lowering chemicals which are thus released into the sea-water would allow the waves to whip up a froth and, if there is also present enough protein matter released from the alginate, a foam with lasting qualities might result.

## Surface Photometry of Southern Elliptical Nebulæ

A PAPER by Dr. David S. Evans on "Surface Photometry of Southern Elliptical Nebulæ", which has been published as No. 19 in the series of "Communications from the Radcliffe Observatory, Pretoria" (reprinted from *Mon. Not. Roy. Astro. Soc.*, 111, 6; 1952), discusses the surface brightness of a group of seven elliptical nebulæ in the region R.A. 3h. to 4h. 30m. Of these nebulæ, four are in pairs and each pair can be photographed on one plate. There is a description of the various details pertaining to the photography, etc., connected with the work, followed by a discussion of the results, which are shown in seven diagrams, these isophotes being drawn with an interval of 0·5 magnitude. In these the dotted lines represent Hubble's distributions in accordance with his law $m = m_0 + 5 \log (r/a + 1)$, where $r$ is the distance measured along a radius and $a$ is a constant. While the maps do little more than confirm Hubble's results, there are certain differences of detail which can best be seen in the plot of *NGC* 1291, the latter showing re-drawings of the central isophotes. There is an obvious rotation of the line of the major axes of successive isophotes, and the natural interpretation of this would be a shear due to rotation. It is asserted that this phenomenon is very probably real in the case of *NGC* 1291, and Evans thinks that this also applies to *NGC* 1549, although the effect is not so well marked. *NGC* 1553 presents some anomalies and resembles two elliptical nebulæ, one seen behind the other, though there is no suggestion that this is so. While it scarcely seems correctly classified as a spiral, as an elliptical nebula it is atypical. Observational material on the remaining bright southern elliptical nebulæ is being accumulated, and it is hoped that a detailed discussion will follow in due course.

## Papain

DERIVED by tapping the mature but unripe green fruits of the papaw (*Carica papaya*), the proteolytic enzyme papain has for a number of years received considerable attention from planters although its market is at present confined largely to the United States. The papaw is indigenous to tropical America, but its cultivation has spread to most tropical countries and its commercial production has hitherto been confined principally to Ceylon and British East Africa (*Col. Plant and Animal Prod.*, 3, No. 1; 1952–53). In the United States papain has five main uses. In the brewing industry it is used for 'chill proofing' beer, while other important applications are in medicine and pharmaceutical preparations; in the food industry, in pre-cooked foods and in the manufacture of meat-tenderizing preparations; and, in the textile industry, particularly in shrinkage resistance and other treatment of wool, wool and silk mixtures, and perhaps in silk processing. Papain is used to a much more limited extent in the United Kingdom, and the chief applications may not extend far beyond pharmacy and textiles. In other countries there would appear to be use for papain in the brewing industry.

## Canadian Association of Physicists: Annual Congress in London, Ontario

THE ninth annual congress of the Canadian Association of Physicists will be held during May 28–30 in the University of Western Ontario, London. Prof. J. T. Wilson, professor of geophysics in the University of Toronto and formerly war-time director of operational research in the Canadian Army, will be the after-dinner speaker at the Association's dinner on May 28, and the presidential address on the structure of physical theories will be delivered on May 29 by G. C. Laurence, of Atomic Energy, Ltd. A reception by the board of governors of the University of Western Ontario will follow. The remainder of the programme of the congress will consist of contributed papers, a symposium on the physics of metals, and two invited papers by Prof. M. S. Vallarta, of the El Collegio Nacional de Mexico, on cosmic-ray physics, and by Dr. H. L. Anderson, of the University of Chicago, on the nature of the $\pi$-meson.

## Eighth Pacific Science Congress: Meeting in the Philippines

THE Eighth Pacific Science Congress will be held in the Philippines (in Quezon City, Manila, Los Banos and Baguio) during November 16–28, with headquarters in the Liberal Arts Building, University of the Philippines, Quezon City; concurrently with this, the Fourth Far Eastern Prehistoric Congress will take place. The programme for the Pacific Science Congress will be organized under the following twelve headings: geology and geophysics, meteorology, oceanography, zoology, botany, soil resources, forestry, agriculture, anthropology, public health, nutrition and social sciences. General symposia will be held as follows : rice enrichment ; Pacific oceanography ; management and utilization of natural resources ; geology and mining industry ; plant geography ; typhoons ; anthropological subjects (with special emphasis on recent archæological finds, outstanding ethnographical studies and problems, and recent work in linguistics) ; historic and prehistoric population movements into the Pacific and major lines of migration ; crop improvement ; animal improvement in the Pacific ; reforestation ; Pacific conservation ; museums ; international organizations of the United Nations, etc. In addition, there will be two special symposia. Besides those who will be at the Congress as official members or members (the latter being appointed by representative institutions or accredited by scientific societies), interested persons may attend the Congress as 'participants' ; British scientific workers who wish to attend should write in the first place to the Assistant Secretary of the Royal Society, Burlington House, London, W.1. Papers will be limited to ten minutes for reading and five minutes for discussion ; all papers (and abstracts of not more than four hundred words) must be sent in by September 1. Further information can be obtained from the Secretary-General, Eighth Pacific Science Congress, National Research Council of the Philippines, Quezon City, Philippines.

## Royal Society of South Africa : Council for 1953

At the anniversary meeting of the Royal Society of South Africa, held on March 18, the following members of Council were elected for 1953 : *President*, S. H. Skaife ; *Honorary General Secretary*, W. J. Talbot ; *Honorary Treasurer*, N. Sapeika ; *Acting Honorary Editor of Transactions*, A. M. Talbot ; *Honorary Librarian*, E. Newbery ; *Other Members of Council*, R. S. Adamson, D. Burnett, W. J. Copenhagen, A. J. H. Goodwin, S. H. Haughton, W. E. Isaac, W. J. Lutjeharms, R. H. Stoy and C. van Riet Lowe.

## Society for Endocrinology: Officers and Committee

Officers and committee for 1953 of the Society for Endocrinology have been elected as follows : *Chairman*, Dr. S. J. Folley ; *Honorary Secretaries*, Prof. C. H. Gray and Prof. N. F. Maclagan ; *Honorary Treasurer*, Dr. G. W. Harris ; *Editor of the Society's Proceedings*, Prof. S. Zuckerman ; *Ordinary Members of the Committee*, Dr. T. Mann, Dr. C. J. O. R. Morris, Dr. I. W. Rowlands and Dr. S. L. Simpson. Communications should be sent to Prof. C. H. Gray, secretary of the Society, at the Department of Chemical Pathology, King's College Hospital, Denmark Hill, London, S.E.5.

## Announcements

A meeting arranged jointly by the Acoustics Group of the Physical Society and the Royal Aeronautical Society on the subject of aeronautical acoustics, and jet noise in particular, will be held at the Institution of Mechanical Engineers on May 21. There will be three sessions on engine, aircraft and ground noise, respectively, and a general discussion will follow. Further information can be obtained from the General Secretary, Royal Aeronautical Society, 4 Hamilton Place, London, W.1.

An exhibition of the Flinders Petrie collection of Egyptian antiquities will be held in the Museum of Egyptology, University College, Malet Street, London, W.C.1, during June 18–August 31 (admission free ; Monday-Friday, 10 a.m.–5 p.m. ; Saturday, 10 a.m.–noon). The Flinders Petrie centenary lecture will be given by Prof. S. R. K. Glanville, Herbert Thompson professor of Egyptology in the University of Cambridge ; the lecture will be open to the public and will be given in the Anatomy Theatre, University College, Gower Street, London, W.C.1, at 5.30 p.m., on June 17.

The summer conference of the Society for Applied Bacteriology will be held in Oxford during July 6–9. On July 7 a symposium will be held on "Antibiotics, their Production and Uses in Industry", at which papers will be read on antibiotic-producing organisms, antibiotic fermentations and their biological control, the chemistry of some antibiotics and their uses in the control of plant diseases and animal feeding. The remainder of the conference will consist of original contributions. Further details may be obtained from the Honorary Secretary, G. Sykes, Boots Pure Drug Co., Ltd., Microbiology Division, West Bridgford, Nottingham.

The annual meeting of the Société de Chimie Physique will this year take the form of a discussion on "Recent Advances in the Study of Molecular Structure", to be held in Paris during July 6–10. The various topics will each be introduced by a general summary given as follows : Sir John Lennard-Jones, principal of the University College of North Staffordshire, recent advances in our knowledge of the chemical bond ; Prof. R. Mecke (Freiburg im Breisgau), recent advances in the field of spectroscopy ; Prof. Roubine (Lille), microwave spectroscopy ; Mr. Grison (Bergerac), localization of hydrogen atoms by X-ray diffraction ; Dr. L. E. Sutton (Oxford), electron diffraction ; Prof. Cauchois (Paris), X-ray spectra ; Dr. G. E. Bacon (Harwell), neutron diffraction ; Dr. M. Lederer (Paris), determination of the molecular structures of natural organic substances. Further information can be obtained from the general secretary of the Société de Chimie Physique, Prof. G. Emschwiller, 10 rue Vauquelin, Paris 5e.

At the combined invitation of the Amsterdams Chemisch Dispuut, the Utrechtse Chemische Club and the Chemisch Dispuut Leiden, Prof. John Read, of the University of St. Andrews, has recently given a series of lectures in the three Dutch universities concerned, beginning at Amsterdam on April 27. In meeting the special request of these three student societies, Prof. Read dealt with the subject of alchemy and its connexions with art and music, and in particular with the art of the Netherlands. The lectures were accompanied by artistic and musical illustrations, and it is a tribute to the linguistic abilities of Dutch students that at each centre the whole of the proceedings, including questions and discussions, were conducted in English. At Amsterdam, in the laboratory of Prof. J. P. Wibaut, Prof. Read also gave an account to advanced and research students, and members of the teaching staff, of some of his own collaborative researches on the chemistry and stereochemistry of plant products, originating in the University of Sydney and continued at St. Andrews.

Erratum. In the communication "Kramer and Russell Effects with Single Crystals of Zinc" in *Nature* of May 16, p. 890, by Dr. L. Grunberg and Dr. K. H. R. Wright, the descriptions (*a*) and (*b*) below the illustration should be interchanged.

# CHEMISTRY AND PHYSICS IN SPAIN

DURING the period April 15–21 the Real Sociedad Española de Fisica y Quimica celebrated its fiftieth anniversary. The proceedings opened with an official reception at which representatives of various foreign chemical and physical societies presented congratulatory addresses, followed by an address on the Society itself by the president, Prof. M. Lora Tamayo. Witness was given to the importance with which science is regarded in modern Spain by the fact that on the dais no less than four ministers of State were present, namely, the Ministers for External Affairs, for National Education, for Industry, and a Minister representing the Sub-Secretariat of the Chief of State. In attendance were the majority of the ambassadors of the foreign delegates. The Minister for National Education welcomed the foreign delegates to Spain.

The actual work of the conference was preceded by a Requiem Mass in the Church of Consejo Superior de Investigaciones Cientificas. Four days were devoted to colloquia and to the communication of papers on original work carried out by Spanish men of science. In addition, a number of open lectures were given on special themes. These included the following: the physical limits of vision, by Prof. J. M. Otero; lignin and its formation, by Prof. K. Freudenberg; the total synthesis of nucleic co-enzymes, by Prof. A. R. Todd; the determination of geological age by isotopic methods, by Prof. Otto Hahn; diene synthesis in natural products, by Prof. Kurt Alder; the role of chromatography, by Prof. A. Tiselius; and electrochemical polarization, by Prof. A. Rius. These alone indicate the truly international character of the meeting.

The meeting also gave opportunity for a reunion of the International Commission on Optics and for the officers of the International Union of Chemistry to discuss the forthcoming meeting at Stockholm.

The Minister for Industry welcomed the delegates and showed them around the permanent exhibit of the activities of the Instituto Nacional de Industria. This is a truly impressive display of the industrial activities which are being developed in Spain. Research work on the lines of that in Britain by the Department of Scientific and Industrial Research is being carried out to the large pilot-plant scale in Madrid on various topics. These include the treatment of shale for the production of lubricants and the utilization of waste raw materials of vegetable origin such as grape stones, sprouts, vine shoots and straw by the process of fermentation followed by briquetting of the non-hydrolysable residue. It is contemplated that 30,000 metric tons a year of yeast for animal consumption, 24,000 tons of petrol and higher ketones for motor fuel, 35,000 tons of wood preservatives and 145,000 tons of charcoal will be produced, together with acetone, methanol and other by-products. The pilot plant has operated successfully, and engineering drawings for the larger plant are now almost completed.

The Instituto Nacional de Industria participates with private firms in a great number of industrial operations which are required for the reconstruction of the national economy in Spain. The outcome of this welding together of national effort and private enterprise will certainly be a matter which the rest of the world cannot ignore.

As will be seen from this brief account of the proceedings of the anniversary meeting of the Society, attendance at and participation in the scientific meetings were tasks of no mean order. In addition, the proverbial Spanish hospitality was on a truly lavish scale, including opera, dinners and tours. Spanish men of science can, at least so far as the foreign delegates are concerned, rest assured that the anniversary celebrations of their Society was an event of outstanding interest. ERIC K. RIDEAL

# RUMFORD BICENTENNIAL SYMPOSIA AND AWARDS

MARCH 26 was the two-hundredth anniversary of the birth of Benjamin Thompson, Count Rumford, who although an American by birth, has left his mark on European science and technology. Apart from his purely scientific achievements, he is best remembered in Britain as the founder of the Royal Institution; he also established the Rumford Medals, one series of which is awarded by the Royal Society and another by the American Academy of Arts and Sciences, the latter for work carried out in America only.

To celebrate the anniversary, the American Academy of Arts and Sciences organized a conference in Boston to which were invited all former Rumford medallists, but which was also open to the scientific public. A great number of the American medallists were present, as well as four medallists of the Royal Society—Sir Alfred Egerton and Prof. F. E. Simon from Britain, Prof. M. Siegbahn from Sweden and Prof. P. Debye from the United States. The celebrations started with a banquet given by the American Academy in the Harvard Club at Boston; the president of the Academy, Dr. Edwin H. Land, of 'Polaroid' fame, presided, and Sir Alfred Egerton transmitted the greetings of the Royal Society and of the Royal Institution. The menu included Rumford's famous soup which he devised for feeding the poor; fortunately, as part of an opulent dinner it produced none of the bad effects it had when for a time, about a hundred years ago, it became the sole diet of the inmates of a British prison! The main speaker was Prof. Sanborn Brown, who gave a very informative and amusing talk on Rumford as a physicist and technologist, and also presented a picture of his personality which made it clear why Rumford was not too popular with many of his contemporaries.

The first symposium was held on the morning of March 27 in the rooms of the Academy and dealt with recent developments in thermodynamics. Prof. P. W. Bridgman spoke on "Reflections on Thermodynamics", Sir Alfred Egerton on "Management of Flame", Prof. L. Onsager on "Reciprocal Relations in Irreversible Processes" and Prof. F. E. Simon on "Helium and the Range of Stability of the Solid State". In the afternoon another symposium took place on recent developments in atomic spectroscopy; Prof. M. Deutsch discussed "Positronium", Prof. W. E. Lamb, jun., "Excited Hydrogen Atoms", Prof. E. M. Purcell "Line Spectra in Radio Astronomy" and Prof. I. I. Rabi "Molecular Beam Radiofrequency Methods for the Study of Excited States of Atoms".

In the evening, Rumford Medals were presented by Dr. Land to Profs. E. Fermi, W. E. Lamb and L. Onsager, who were introduced by Profs. P. Debye, N. F. Ramsey and J. G. Kirkwood, respectively. After the ceremony a reception for the Rumford Medallists was held in the very pleasant rooms of the American Academy of Arts and Sciences. There was also an opportunity of visiting an exhibition of Rumford's scientific works.

On March 28 there was a final symposium on recent developments in nuclear physics. The speakers were Prof. E. Fermi on "Meson Physics", Prof. J. R. Oppenheimer on "Recent Progress in the Understanding of Nuclear Forces", Prof. M. Siegbahn on "Nuclear Spectroscopy" and Prof. V. F. Weisskopf on "Problems of Nuclear Structure". All the symposia were followed by lively discussions, and as there were not more than about a hundred people present the intimate atmosphere contributed very much to the outstanding success of the meetings.

The symposia were organized in a quietly efficient way, and the guests were sincerely grateful for the gracious and generous hospitality accorded to them. Their thanks are due to the officers and staff of the American Academy, in particular to Prof. Harlow Shapley, the chairman of the Rumford Bicentenary Committee, and to Mr. R. W. Burhoe, the executive officer of the Academy.

F. E. SIMON

## THE BRITISH DYESTUFFS INDUSTRY

THE address, "Our Changing Chemical Industries: an Appraisement", which Dr. Herbert Levinstein delivered to the British Association of Chemists on February 27 on the occasion of the award to him of the Hinchley Medal, further expounds a disturbing passage in Sir Henry Tizard's Messel Memorial Lecture last July. Sir Henry Tizard had expressed disquiet at Britain's apparent lack of success in competing in the world's markets for chemicals, and quoted figures to show that our share of world trade in chemicals had gone down steadily from 22 per cent in 1913 to 18 per cent in 1950. Germany had been out of the world's markets twice in this period and her share fell from 37 per cent in 1913 and 36 per cent in 1937 to 11·5 per cent in 1950. Dr. Levinstein recognized that the chemical industry in Britain is changing in character as, in accordance with the general tendency to expansion across industrial frontiers rather than within them, firms like the Distillers' Co. and the petroleum firms have extended their manufacturing activities far beyond their original field. There are now in Britain half a dozen firms, with large capital, making chemicals, whereas formerly there was only one; however, we have not yet begun to reap full advantage of the operations of these big companies.

These changes should substantially strengthen the chemical industry of Britain, diminish dollar imports and help exports; but nevertheless, Dr. Levinstein urged that there is much to justify Sir Henry Tizard's misgivings. Arguing that in Britain, as in Germany and in Switzerland, the dyestuffs industry is the foundation of organic chemical industry, he suggested that consideration of the beginnings of this industry, the reasons for its leaving its birthplace in Britain, and its growth to really gigantic proportions in Germany would explain much that has disturbed Sir Henry Tizard. Reviewing the beginnings of the industry and its decline in Britain by the 'seventies, Dr. Levinstein said that the absence of a patent law in Germany until 1877 and, until much later, in Switzerland, and of any provision in British patent law for working in Britain, allowed German and Swiss inventors to take out British patents without obligation to manufacture here, while during this period they could infringe British or other patents in their own countries. The weakness of the British patent system was also exploited by the Germans during 1877–1914, after the Imperial patent law of 1877 embodied Caro's definition of a chemical invention, namely, the obtaining of a new and unexpected technical effect.

The imposition in Britain of the same duty on pure alcohol for industrial purposes as on potable spirits also gave a great advantage to the Germans, and this was not modified until nearly thirty years later when the Government wished to make cordite. A further factor was the difficulty in obtaining capital for new and risky developments, a position which persisted until the comparatively recent formation of the Finance Corporation for Industry. Dr. Levinstein dismissed as irrelevant the view that the superior education of the German chemist or the neglect of research by the British manufacturer had played any real part in the transfer of the dyestuffs industry to Germany. It is true, he said, that training in organic chemistry was better in Germany and in Switzerland than in Britain in the early years of the period. The first large and distinguished school of organic chemistry in Britain was under W. H. Perkin, jun., at the Victoria University, Manchester; but there was never any difficulty in obtaining good German, Swiss, or British chemists from abroad. As regards research, Dr. Levinstein claimed that more research was carried out by his firm at Blackley than was justified by the sales, and that, although on a modest scale compared with that of the Germans, far more research was done there than by any other firm in Britain.

Reviewing the achievements in restoring the British industry on the outbreak of war in 1914, and which, in fact, prevented the Germans from using their stocks of dyestuffs for bargaining at the Peace Conference, Dr. Levinstein pointed out that in 1919 imports into Great Britain had fallen to 3,232 tons from 18,900 tons in 1913, and that we were already exporting 5,446 tons. Although the British range of dyes was incomplete and the plants employed were not necessarily the best for peace conditions, the back of the task was broken and a large research organization had been established. Delays in implementing the promise to introduce the Dyestuffs (Import Regulation) Act and other political and economic factors led to the partial dispersal of the research and technical staff; but Dr. Levinstein expressed his concern that a recent book, "Twenty-five Years Ago, the Story of the I.C.I. Merger", issued by Imperial Chemical Industries, Ltd., had not given a fair account of what had been done to re-establish the British dyestuffs industry before that combine was formed. He also contested the claim that the Dyestuffs Act was only intended to protect the home market and not, by securing the home market, to build up exports. The object of the Act was to secure for the home market a wide, substantially complete range of dyestuffs ; but if exports were neglected, overheads would be extravagantly high. The highest export of British dyestuffs before the Second World War was in 1929, and only in that year and in 1937 (5,728 tons) were the figures for 1919 (5,446 tons) and 1920 (6,157 tons) exceeded. In nineteen years under the Dyestuffs Act, nothing was done to increase British exports of dyestuffs.

This, Dr. Levinstein suggested, had some bearing on the figures which caused Sir Henry Tizard concern. Moreover, there had been no further reduction in imports, which averaged 2,325 tons during 1919–26 (including the abnormally high figures for 1920, following the Sankey judgment) and also for 1927–38. The post-war period figures showed improvement. Exports increased to 12,148 tons in 1950 and 12,486 in 1951, and thus do not substantiate the claim that the German firms have recovered their lost ground. On the other hand, imports increased from 786 tons in 1950 to 1,657 tons in 1951, and of these last Dr. Levinstein noted that 676 tons came from Switzerland and 220 tons from the United States, as much being paid to these 'hard currency' countries as we paid to Germany in 1913. Dr. Levinstein also noted that there are now thirty-seven dyestuffs makers in Britain, and he concluded his survey by referring to the potentialities of the small firm and the possibility of formidable competition later from the U.S.S.R. in dyestuffs and in other chemicals.

# FOOD PRODUCTS FROM PLANTS

THE Nutrition Panel of the Society of Chemical Industry, at the third of its series of meetings on "Food and the Future", held in the rooms of the Chemical Society, London, W.1, on March 25, discussed the subject of "Newer Sources of Foodstuffs". Two papers were under discussion : one by Dr. A. C. Thaysen, of the Colonial Microbiological Research Institute, Trinidad, on food and fodder yeast, and the other by Mr. N. W. Pirie, of the Rothamsted Experimental Station, on the efficient use of sunlight for food production.

Dr. Thaysen's paper pointed out that the process of making use of waste material as a medium for the growth of yeast is a measure of our shortage of food. The original idea for the use of yeast as a human food was for children in countries experiencing undernutrition where the need for supplementary protein is most acute. The value of yeast lies in its ability to convert about 80 per cent of the inorganic nitrogen supplied into protein. The rate of conversion, compared with more orthodox methods, is enormous : for example, a fully grown bullock, weighing half a ton, produces protein at the rate of 0·9 lb. per day ; half a ton of soya beans at the rate of 82 lb. per day ; and half a ton of *Torulopsis* could produce protein at the rate of 51 tons in 24 hr.

Food yeast is at present being produced both in Jamaica and in South Africa. The cost, at 1*s*. 2*d*. per lb., corresponds to 0·069*d*. per lb. of protein, compared with 0·8*d*. per lb. of protein from beef. However, very little yeast is at present consumed by man. In Germany and Finland it is used solely as animal feed, and, if the comparison is then made between yeast and other sources of animal feed, the economic aspect, at the present time, is unfavourable ; thus food yeast sells at £130 per long ton, compared with soya bean meal at £30. It is necessary to take into account the presence of an appreciable concentration of vitamins in the yeast. As a supplement to human dietaries, apart from its protein content, yeast would supply much-needed members of the vitamin B-complex and, used in this way, is certainly economical.

In the absence abroad of Dr. Thaysen, his paper was introduced by Mr. H. J. Bunker, who emphasized the future possibilities of food yeast, when present economics could be considered irrelevant. He pointed out that dried brewers' yeast sells at £90 per ton, and when debittered, but not extracted, at £130.

The value of *Torulopsis* as a food converter, compared with *Saccharomyces*, lies in its ability to ferment pentoses as well as hexoses. This is valid only when waste sulphite liquor is used as a medium ; when grown on molasses, both these organisms are equally valuable. Vast quantities of raw material are available : for example, as much as a quarter of a million tons of waste sulphite liquor, which really is a waste material, is available annually in the United States and Canada, as well as hydrolysed wood, banana skins, bracken and peat.

*Rhodotorula gracilis* could provide a valuable addition to fat resources, as the organism contains 42 per cent fat and 23 per cent protein. Earlier reports of the unpalatability of yeast, when it was said that only about 15 gm. per day could be consumed without causing digestive disorders, were probably due to contamination with defrothing agents. Well-prepared yeast is quite palatable.

Mr. Pirie said in his paper that at present we are entirely dependent upon sunlight for our food supplies ; but photosynthesis is extremely inefficient. Much of the light is reflected, absorbed by inactive surfaces or by surfaces which are rendered inactive because of unsuitable conditions. The advocates of unicellular photosynthetic organisms, such as *Chlorella*, dispute that farming is the best way to produce food. Algæ have, however, no greater efficiency in trapping sunlight, but can be more readily made to work at maximum efficiency by provision of optimum temperature, carbon dioxide and nutrients. These conditions would render *Chlorella* culture as costly as glasshouse cultivation. It was pointed out later in the discussion, however, that efficiencies up to 20 per cent have been achieved by growing *Chlorella* in the open, as compared with 2–3 per cent for ordinary crops. In addition, the plasticity of metabolism of the organism permits production of food material of any desired composition : for example, 60 per cent protein : 5 per cent fat or 10 per cent protein : 80 per cent fat.

As the green plant will be our main source of food for a long time to come, the best use must be made of it. Only a small part of the crop is eaten directly by man ; most is fed to animals or used as a fertilizer, or even wasted. Crops grown primarily as animal food are wasteful, despite the high esteem in which their products are held, because the overall conversion is usually only 5–10 per cent. Economies in the use of soil can be made both here and by replacing textile fibres by synthetic fibres.

The direct consumption of crops by man is desirable. Plants are, however, relatively poor sources of protein, with the exception of legume seeds and most young leaves. Young, vigorously growing leaves contain up to 30–40 per cent protein and little fibre ; but only a few plant species will stand up to continuous cropping of very young leaves. The alternative is to separate the fibre from the proteins, fats and carbohydrates of lower-quality leaves. The advantage of fractionating leafy crops lies in the fact that the products are more valuable when separated than when combined. The proteins are suitable for non-ruminants and perhaps man, the fluid extract could be used for feed or as a medium for micro-organisms, and the fibrous residue, still containing some proteins and starches, is suitable for ruminants or even for fuel.

In many parts of the world there are abundant leafy wastes, such as potato haulms, sugar-beet leaves and sweet potato leaves. When, however, satisfactory techniques have been developed, our choice of domesticated plants might well be reconsidered. Plants that use sunlight most efficiently might be chosen rather than those grown merely because a use has been found for them. On the question of economics, leaf protein, even extracted from crops grown specially for the purpose, would cost less than existing protein foods and about the same as estimates for yeast and *Chlorella*.

The discussion revealed two trends of thought on these new natural sources of foodstuffs. One was that orthodox agriculture would see us through this century and that these novel methods should await the development of new techniques. The other was that present drawbacks to these new foods are largely due to lack of information and that further investigation is most desirable. As Mr. Pirie said, all methods of increasing the world's food supply must be pushed ahead, for they are complementary rather than conflicting.

A. E. Bender

# BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

## ANNUAL REPORTS FOR 1951 AND 1952

THE recently received third annual report of the council of the British Gelatine and Glue Research Association (pp. 13; 1951) covers the year October 1950–September 1951, and the fourth (pp. 19; 1952) for that ending in September 1952. The former report records an increase of two in the full membership but no change in the staff. Two meetings of the Research Panel were well attended, the second, a symposium on the uses of gelatine and glue, providing a valuable opportunity for interchange of views between manufacturers and users. It was decided that at future meetings, in addition to papers of the type previously presented, accounts would be given of the research work of the Association; and the visit to the laboratories, which is a regular feature of Panel meetings, has proved a valuable link between the Association's staff and that of member firms. The fourth annual report records two additions to associate membership and one to full membership, as well as the appointment of an additional research officer for work on the physical and mechanical properties of gelatine and glue. The laboratories were officially opened on November 29, 1951, by Sir Robert Duncalfe, and two further meetings of the Research Panel are reported (see *Nature*, 169, 24 (1952); 170, 24 (1952); and 171, 250 (1953)).

The reports of the Director of Research, included with each of these annual reports, indicate that during the next two or three years a substantial body of new knowledge concerning gelatine and glue will have been built up. Work on the purification of gelatin by ion exchange resins, for example, has shown that the ash content of gelatin is reduced from 2–3 per cent to 0·005 per cent by passing a 5 per cent solution through a mixed bed of the 'Amberlite' resins *IR*120 and *IRA*400. Even very high arsenic contents can thus be reduced below the limit prescribed for edible gelatine, and the method provides a ready means of determining isoelectric points. Detailed studies of the viscosity of very dilute solutions of gelatin have shown that the gelatin molecule is in a partly folded configuration at its isoelectric point, the equal and opposite charges along the molecule contributing to the folding. The technique developed by F. Sanger, in which fluorodinitrobenzene reacts with free amino groups of proteins, has been applied to the determination of end-groups in gelatin, and studies have also been made of the organic constituents of bone, while new methods have been developed for estimating the colour and clarity of gelatine and glue solutions and gels and for the accurate determination of arsenic in gelatine. A device has been constructed to facilitate accurate testing of jelly 'strength', and a detailed investigation of sampling errors in bacterial counts on powdered gelatine indicates that the variation is related to irregular distribution of bacteria in the gelatine, probably originating from the drying operation.

---

# WORLD-WIDE CHANGES IN THE PHASE OF THE COSMIC-RAY SOLAR DAILY VARIATION

By T. THAMBYAHPILLAI and Dr. H. ELLIOT
Physical Laboratories, University of Manchester

MEASUREMENTS of the cosmic-ray diurnal variation at sea-level using directional counter arrays[1] have shown that the variation is at least in part due to an anisotropic distribution of the primary radiation entering the atmosphere. Since the variation is dependent on solar rather than sidereal time,

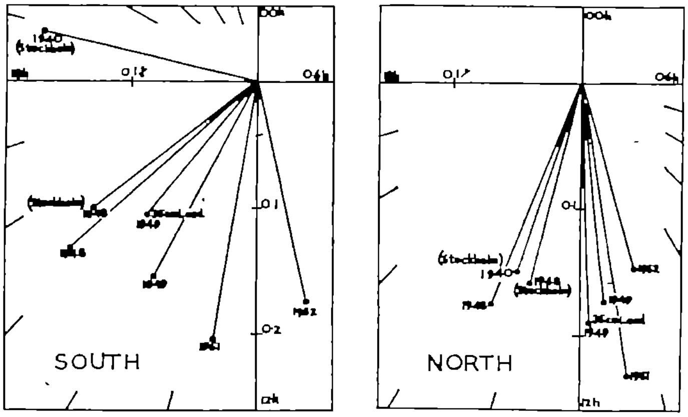

Fig. 1 Harmonic dials showing the first harmonics of the daily variation measured in Manchester and Stockholm using counter telescopes pointing south and north. All the measurements have been made using unshielded telescopes with the exception of one set of data for Manchester in 1949, when 35 cm. lead absorber was used

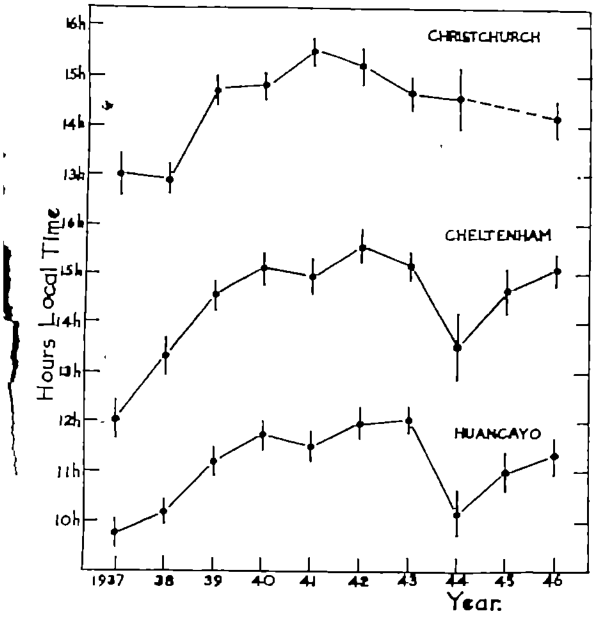

Fig. 2. Times of maximum for the first harmonics of the daily variation as measured by ionization chambers at Christchurch (lat. 43° S.), Cheltenham (39° N.) and Huancayo (12° S., 3,350 m. altitude)

the anisotropy is evidently caused in some way by the sun, and it is therefore important to ascertain whether there is any relation between the variation and the sunspot cycle. Earlier measurements in Manchester have therefore been repeated during the past two years, using the same apparatus as was used in 1948 and which consists of two counter telescopes with rather wide angles of acceptance, one pointing south and the other to the north and inclined at 45° to the vertical.

Fig. 1 shows the first harmonics of the annual mean daily variations plotted on a harmonic dial for 1951 and 1952, together with the earlier measurements in Stockholm and Manchester. It will be seen that there appears to have been a significant change in the daily variations between 1940 and the present time. The time of maximum for the south-pointing telescopes has fallen progressively earlier in the day from 1940 to 1952. There is a similar but much less marked trend for the north direction. The changes in amplitude over this period are not significant.

In view of these results, the ionization chamber data published by the Carnegie Institution of Washington[2], for Cheltenham (U.S.A.), Christchurch (N.Z.) and Huancayo (Peru), covering the period 1937–46 have also been examined. The first two stations are close to sea-level and at very nearly the same latitude (~ 40°) in the northern and southern hemispheres, respectively, whereas Huancayo is close to the equator and at an altitude of 3,350 m. The average diurnal variations at Christchurch and Cheltenham over the whole period 1937–46 have very nearly the same amplitude and phase, whereas that for Huancayo has the same amplitude but the time for maximum is 3·3 hr. earlier than at the other two stations. The phases of the annual mean daily variation at the three stations are shown plotted in Fig. 2 for each year. It will be seen that phase-changes have occurred during this period, and that the changes are roughly parallel at the three stations, indicating that they are not local in origin.

In Fig. 3 we have plotted all the data on the phase of the diurnal variation which are readily available. In all cases except the Hafelekar observations, a correction for barometric pressure only has been made. The Hafelekar observations, as published, had in addition been corrected for atmospheric temperature, and to this extent there is an uncertainty as to whether they are directly comparable with the observations from the other stations. Where directional counter measurements have been used, the mean variation for the two directions has been plotted. The Huancayo points have been displaced by a constant amount corresponding to 3·3 hr. to bring them into line with the other stations.

It will be seen that, although the points show a certain amount of scatter, there appears to have been a systematic change in phase over the years. The time of maximum fell progressively later from 1933 to 1942, and then the time of maximum has become gradually earlier from 1942 up to the present. It has been shown by Sekido and Kodama[3] that there is a relation between the phase of the diurnal variation and geomagnetic activity, the time of maximum falling earlier on days of high activity than on days which are undisturbed magnetically. It appears, however, that the changes in phase shown in Fig. 3 can at best be only partially accounted for in this way, since geomagnetic activity shows a predominantly 11-year cycle and the points in the

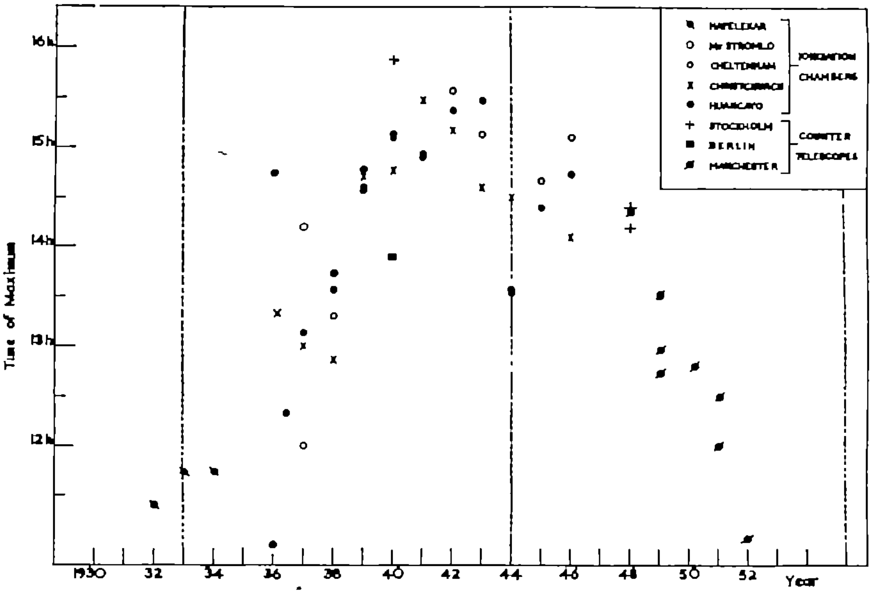

Fig. 3. Time of maximum of the first harmonics of the diurnal variation. The years of sunspot minimum are indicated by the broken lines

diagram do not show such a periodicity to any marked degree. The years of sunspot minimum are indicated by the broken lines in Fig. 3, where it will be seen that the minimum of 1933 corresponds to an early time of maximum for the daily variation and it appears likely that a similar state of affairs will hold for the next minimum (1955). The intervening minimum of 1944, however, corresponds to a late time of maximum. It is worthy of note that if the phase change is a periodic effect, the data in Fig. 3 could be fitted to a 22-year wave, which is, of course, the true period of the sunspot cycle. It is impossible at this stage to say with certainty whether or not the cosmic-ray data do show such a cycle, and many more years of systematic observation will be required to produce a conclusive result. There can be little doubt, however, that systematic changes in the phase of the diurnal variation do occur on a world-wide scale.

We are indebted to Dr. A. R. Hogg and Dr. D. I. Dawton for providing us with the results of their measurements on the daily variation. [April 23.

# FORMATION OF LABILE PHOSPHATE ESTERS BY IRRADIATION OF NUCLEIC ACIDS WITH X-RAYS IN AQUEOUS SYSTEMS

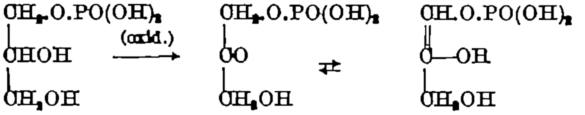
By Dr. GEORGE SCHOLES and Dr. JOSEPH WEISS

University of Durham, King's College, Newcastle upon Tyne

WHEREAS previously the action of X-rays on aqueous solutions of nucleic acids was considered to be essentially of a physical nature, studies carried out in this laboratory have established that definite chemical processes take place during the irradiation[1-4]. At lower doses of radiation, these chemical effects include the formation of ammonia and of inorganic phosphate; by using higher doses the formation of certain free bases and of titratable acid groups in addition could be shown. On the basis of these and other experimental findings, a tentative mechanism for the overall attack of the radicals produced by the radiation has been proposed[3,4]. The experiments seemed to suggest that hydrolysis of certain labile substances plays a part and that these substances include labile phosphate esters. However, the evidence then available was largely of an indirect nature.

We have now obtained some direct experimental evidence on this point, this being based on the fact that labile phosphate esters are more or less easily hydrolysed with the formation of inorganic phosphate. Blank and irradiated nucleate solutions were hydrolysed by dilute acid (under standard conditions) and the amount of liberated inorganic phosphate determined by the method of Berenblum and Chain[5]. In this way we have been able to show that, for example, with doses of the order of $9 \times 10^4$ r-units, in the presence of oxygen, the additional amounts of inorganic phosphate liberated from irradiated ribonucleic acid and deoxyribonucleic acid solutions are about fifteen times the amounts of free phosphate formed during the irradiation.

A study of the effects of X-rays on some relatively simple organic phosphate esters has shown that these can serve to some extent as model compounds. Among the substances investigated from this point of view were α- and β-glycerophosphate and 3-phosphoglyceric acid. Here again, further appreciable amounts of inorganic phosphate were released on subsequent hydrolysis of the irradiated solutions, although the acid-lability of these intermediate esters was rather lower than the lability of the esters formed from the nucleic acids. The interest in these three-carbon systems arises from the fact that the point of attack by the oxidative radicals can be predicted on chemical grounds with some degree of certainty. Such considerations would suggest that the formation of labile phosphate esters, for example, by irradiation of α-glycerophosphate solutions, results from an oxidative attack on the secondary alcohol group (β-position) according to the following reaction:

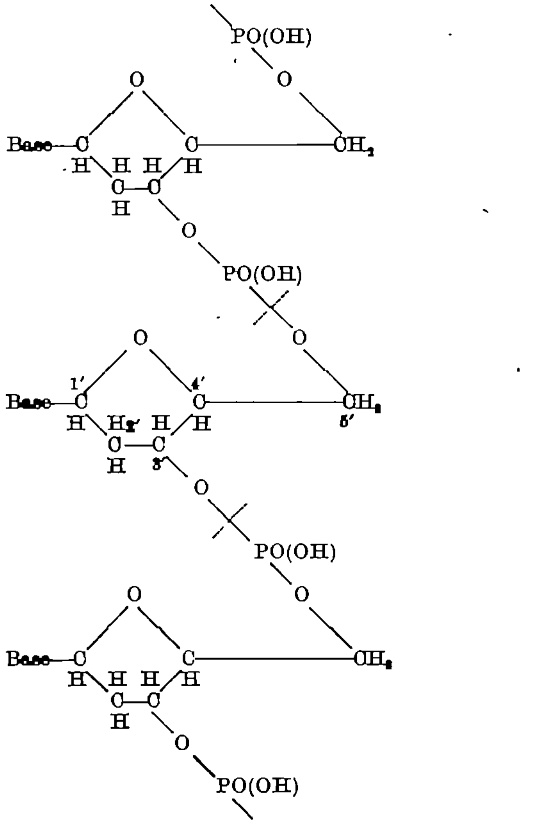


$$\begin{array}{l} CH_2.O.PO(OH)_2 \\ | \\ CHOH \\ | \\ CH_2OH \end{array} \xrightarrow{(oxid.)} \begin{array}{l} CH_2.O.PO(OH)_2 \\ | \\ CO \\ | \\ CH_2OH \end{array} \rightleftarrows \begin{array}{l} CH.O.PO(OH)_2 \\ \| \\ C-OH \\ | \\ CH_2OH \end{array}$$

(I)

It is apparent that the acid lability of the irradiated solutions can be due here to the formation of compounds similar to (I).

In the case of the nucleic acids, we have already presented evidence that both the basic and pentose

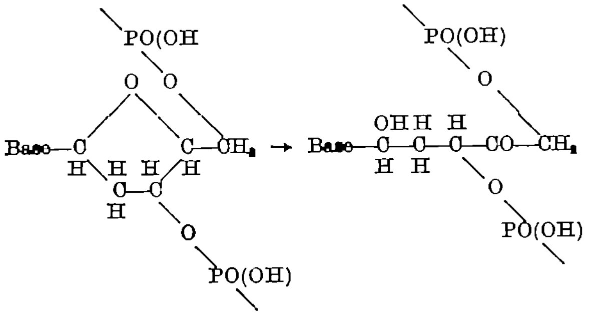


constituents are attacked by the radicals produced during irradiation, and it is possible that chemical changes in either of these components may increase the acid-lability of the resulting product.

The following discussion is limited to the labile esters which can arise by oxidation of the sugar part.

A small section of, for example, deoxyribonucleic acid can be represented as shown on p. 920. From this scheme it is obvious that the pentose —C(4′) atom occupies a unique position in this structure in that it is adjacent to two phosphate groups; oxidation at this centre, therefore, should have a pronounced labilizing effect. Furthermore, electrostatic interaction between the two phosphate groups may be an additional factor in their mutual labilization[6]. Subsequent hydrolysis of the labile phosphate bonds produced in this way will lead to a transverse fission of the polynucleotide chain with the production of both (3′)– and (5′)– (end) phosphate groups. When the (5′)– phosphate is already an end group, this should lead directly to the formation of inorganic phosphate.

If, on the other hand, there is an oxidative attack at C(3′) or C(5′), this will lead to an immediate scission of the corresponding phosphate bond without the intermediate formation of a labile ester. In deoxyribonucleic acid, neither oxidation at C(1′) nor at C(2′) should have any labilizing effect on the phosphate linkages. In ribonucleic acid, oxidation at C(2′), which here is a secondary alcohol group, could labilize the phosphate in the (3′)– position. On chemical grounds, however, it appears that C(4′) in both nucleic acids is rather vulnerable and a likely point of attack. Further, it is to be expected that oxidation at this position should also lead to an opening of the furanose ring:



Therefore, in addition to labilization of the adjacent phosphate bonds, the glycosidic linkage may also be considerably weakened, leading to the liberation of the base; the presence of free bases in irradiated nucleate solutions has already been observed previously[1].

These considerations may also be of some importance for the understanding of the mechanism of the 'after-effect' in deoxyribonucleic acid solutions[7,8], namely, the decrease in viscosity which continues for some time after cessation of irradiation. We have already stated[2,3] that some of the immediate loss of viscosity may be closely associated with a loss of 'hydrogen bonding', particularly through elimination of polar groups by the action of the radicals upon the constituent bases and possibly to some extent by elimination of phosphate end groups. Furthermore, an immediate scission of the polynucleotide chain should be brought about by oxidative attacks at the pentose C(3′) and C(5′), as pointed out above.

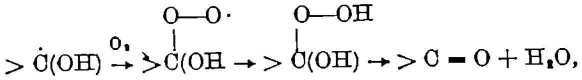
On the other hand, with regard to the post-irradiation effect, our results suggest that this may be due to the following reactions: (a) Transverse fission of the polynucleotide chain by hydrolysis of 'labile' phosphate esters as outlined above. This may be accompanied by loss of the corresponding base, and thus loss of some hydrogen bonds. (b) Attack at the double (ethylenic) bonds of the pyrimidines by the free radicals and (hydrolytic) liberation of the chemically changed base from the main polynucleotide chain.

It has been stated that the 'after-effect' in irradiated deoxyribonucleic acid solutions depends entirely upon the presence of oxygen[8,9]. However, this appears to be somewhat unlikely in view of the fact that there are also oxidizing (OH) radicals present under vacuum conditions. The effect of molecular oxygen has been studied in a number of other systems; for example, in the formation of acetaldehyde from alcohol[10], or of pyruvic acid from lactic acid[10] and from alanine[10], the ratios of the yields in the presence and absence of oxygen were found to be between 3 and 6, depending on the substance and on the experimental conditions. Therefore, the presence of oxygen during irradiation of the nucleic acids should only enhance the extent of oxidative attack upon the basic and pentose components.

In evacuated solutions, for example, the oxidation of a secondary alcohol group of the sugar would require a process similar to:

$$>CH(OH) \xrightarrow{OH} >\dot{C}(OH) \xrightarrow{OH} >C = O.$$

In the presence of oxygen, on the other hand, because of the process $H + O_2 \rightarrow HO_2$, the effective number of OH radicals may be increased by inhibiting the recombination of the primarily formed H and OH. Probably more important still, the yield may also be increased by reaction of the initially formed organic radicals with oxygen:



$$> \dot{C}(OH) \xrightarrow{O_2} >\overset{O-O\cdot}{\overset{|}{C}}(OH \rightarrow > \overset{O-OH}{\overset{|}{C}}(OH) \rightarrow > C = O + H_2O,$$

that is, via a peroxide radical, which can eventually lead to the corresponding carbonyl compound.

All these experiments refer to *in vitro* conditions, and therefore any conclusions drawn from them with regard to the biological action of X-rays on nucleic acids are bound to be highly speculative. However, it is perhaps worth pointing out that there may be a connexion between the labile phosphate esters produced by the action of, for example, X-rays on nucleic acids and 'high-energy phosphate bonds'.

In general, observations on the lability of phosphate esters may also be of use in the elucidation of the point of attack of the free radicals.

Full details of this work will be published elsewhere.

# POSITION OF HÆMS IN THE HÆMOGLOBIN MOLECULE

By PROF. D. KEILIN, F.R.S.
Molteno Institute, University of Cambridge

ONE of the problems which arises from the study of the mechanisms of oxygenation and oxidation reactions of hæmoglobin is the position occupied by the hæms in relation to the globin. The solution of this problem is of paramount importance for the proper understanding of the structure of hæmoglobin and of the interactions between the hæm and the protein in hæmoglobin, as well as in other natural hæmoprotein compounds.

The nomenclature of hæmoglobin and its derivatives which will be used in the present study comprises the classical terms which have previously been discussed and defined[1,2]. Although the term 'hæmoglobin' will be applied here in its widest sense, covering all hæmoprotein oxygen carriers, irrespective of their origin, but having protohæm as their prosthetic group[3], the position of hæms will be examined mainly in mammalian hæmoglobins (molecular weight 68,000) which have four hæms per molecule.

## Imidazole Theory of Hæm-linked Groups in Hæmoglobin

It was undoubtedly the high histidine content of hæmoglobin that was primarily responsible for the view that the imidazole ring of this amino-acid forms the link between the hæm–iron and the globin. This view received some support from Langenbeck's[4] observation that hæmatin easily combines with different imidazoles, forming, especially with 4-methyl imidazole, very stable parahæmatin compounds. A more definite formulation of this view was made by Conant[5], who, in his Harvey Lectures, suggested that globin is linked to each hæm–iron through two imidazole rings of histidine residues of which one, being more easily displaced by oxygen than the other, forms the oxylabile group responsible for the well-known Bohr effect. However, it was Wyman and his co-workers[6,7,8] who made the first attempt to obtain more direct experimental evidence in support of this theory. The main results of this work were recently summarized by Wyman[9] in a masterly review of different aspects of hæmoprotein compounds. In the course of these investigations[6,7] they found that the heat of ionization of titratable groups between $pH$ 5·5 and 8·5, calculated from the effect of temperature upon titration curves of hæmoglobin, was about 6,500 cal., which is very close to that of the imidazole group of histidine. Moreover, by comparing the effect of temperature on titration curves of hæmoglobin and oxyhæmoglobin, they were able to find that the heat of ionization of the oxylabile acid groups lies very close to that of the imidazole group of histidine. They concluded that the hæm–iron in hæmoglobin is linked with two imidazole groups of histidine residues, being, however, closer to one group than to the other. It is somewhat difficult to reconcile the result of this work, which indicates that the hæm–iron lies between two histidine residues, with one of the conclusions of Wyman's review[9], namely, that hæms in hæmoglobin lie attached to the surface of globin.

The imidazole theory also received support from magnetic susceptibility measurements carried out by Pauling and his co-workers, who were able to determine the nature of the bonds uniting the hæm–iron with the surrounding atoms and to offer the first structural interpretation of the hæm-linked groups in hæmoglobin and its derivatives[10].

## Critical Examination of the Theory of the Embedded Position of Hæms

One of the important deductions which can be drawn from the imidazole theory of the hæm-linked groups, as formulated by Conant, Wyman and Pauling, is that the disk-like hæms lie within a fold or crevice of the globin. The concept of the embedded position of hæms was recently used by Pauling[11,12] and by St. George and Pauling[13] as a basis for an ingenious steric hindrance theory to account for the *S*-shaped oxygen equilibrium curve of hæmoglobin and for the hæm–hæm interaction. According to this theory, the enfolded positions of the four hæms between the layers of globin will limit the accessibility of oxygen to the hæm–iron. However, when an oxygen molecule reaches the first hæm–iron to form the oxygenated complex, the protein structure becomes somewhat loosened and thus makes the second hæm–iron more easily accessible to oxygen. With the formation of successive oxygenated complexes, the degree of hindrance to the penetration of oxygen progressively decreases, and this is reflected in the sigmoid curve of the reversible reaction between hæmoglobin and oxygen.

Since the steric hindrance theory is based upon the assumption that the four hæm groups of hæmoglobin are buried within the globin, St. George and Pauling (1951)[13] made an attempt to obtain more direct evidence in support of their view. For this purpose they investigated the reactions of free hæm and hæmoglobin with different alkyl isocyanides, such as the ethyl, isopropyl and tertiary butyl derivatives. They found that, whereas the nature and size of these isocyanides had no influence upon their affinities for free hæm, they had a marked effect upon their affinities for hæmoglobin. Thus, the affinity of hæmoglobin for isopropyl and tertiary butyl isocyanides was about 3 and 200 times lower respectively than its affinity for ethyl isocyanide. They ascribed this fall in the affinity to the increasing molecular sizes, and therefore to increasing difficulties of penetration of these isocyanides between the protein layers enfolding the four hæms.

However plausible and attractive may appear the theory of the embedded position of hæms in hæmoglobin and of the steric hindrance theory of hæm–hæm interaction, several important experimental results militate against them. Neither of these theories can therefore be accepted without a careful examination of these results, which can be summarized as follows.

(1) *Reactions of hæmoglobin with oxidising and reducing agents.* It is well known that the divalent iron of hæmoglobin is oxidized by potassium ferricyanide ($K_3Fe(CN)_6$) and by methylene blue to the trivalent iron of methæmoglobin, and that the latter is reduced back by sodium dithionite ($Na_2S_2O_4$) to hæmoglobin. All these substances are much larger in size than a molecule of oxygen or of carbon monoxide. In fact, the reactions of hæmoglobin with ferricyanide and methylene blue have already been considered as an indication that the hæms lie attached to the surface of the globin[14]. Moreover, these reactions are of special interest considering that

neither ferricyanide nor dithionite ions can penetrate the cell membrane of the red blood corpuscles, facts which make possible the spectroscopic study of the mechanism and the kinetics of lysis, by different agents, of erythrocytes containing either hæmoglobin or methæmoglobin[15].

(2) *Formation of compounds with nitrosobenzene and imidazoles.* It has been shown that the divalent iron of free hæm and of hæmoglobin combines reversibly with nitrosobenzene forming spectroscopically well-defined complexes[16,17]. The same complexes are obtained when hæmatin and methæmoglobin are treated with phenyl hydroxylamine ($C_6H_5NHOH$). In this reaction phenyl hydroxylamine reduces free hæmatin and methæmoglobin to hæm and hæmoglobin respectively, while it is itself oxidized to nitrosobenzene ($C_6H_5NO$), which then combines with hæm and hæmoglobin[17].

It has also been shown that the trivalent iron of methæmoglobin combines reversibly with 4-methyl imidazole[18], forming a compound with an absorption spectrum of the parahæmatin type. Since the reactions of hæmoglobin and methæmoglobin with oxidizing and reducing substances consist in electron transfer between these substances and the hæm–iron, one cannot dismiss the possibility that such reactions take place indirectly through some groups belonging to the protein. Thus, the oxido-reduction reactions by themselves do not necessarily rule out the possibility of embedded hæms. However, the position is very different in the cases of nitrosobenzene and imidazole, which form co-ordination complexes with the iron of hæmoglobin and methæmoglobin respectively. To form such complexes the hæm–iron must be directly accessible to these substances.

Thus the view that hæms in hæmoglobin are embedded within a fold of globin which may hinder the penetration of oxygen molecules to the hæm–iron is difficult to reconcile with the facts that large polyvalent ions such as ferricyanide and dithionite or comparatively large molecules such as methylene blue, nitrosobenzene, phenyl hydroxylamine and imidazole can easily reach the iron of hæmoglobin or methæmoglobin and react or combine with it.

(3) *Reactivities of free hæmatin and of hæmatin bound to native protein.* The difference in the ability of a free hæmatin and of a hæmatin forming part of a native hæmoprotein to combine with certain substances cannot always be ascribed to the possible greater accessibility of the iron in the free hæmatin. In fact, the hæmatin of methæmoglobin may show a much greater reactivity towards certain substances of small molecular size than does free hæmatin. Thus, whereas methæmoglobin easily combines with azide[19], fluoride[20] and hydrosulphide[21] ions, to form well-defined compounds, free hæmatin forms no spectroscopically recognizable compounds with these substances. Moreover, the easily observed reactions of methæmoglobin, catalase and peroxidase with peroxides are in striking contrast to the great difficulties in demonstrating any of these reactions with free protohæmatin. Indeed, only urohæmatin has been found to form well-defined compounds with hydrogen peroxide and ethyl hydroperoxide[22]. On the other hand, of a variety of substances which combine with free hæmatin, only cyanide, nitric oxide and certain imidazoles combine with methæmoglobin, and of a still larger variety of substances which combine with free hæm[23], only cyanide, alkyl isocyanides, nitric oxide, carbon monoxide and nitrosobenzene combine with hæmoglobin.

(4) *Absorption spectra and nature of hæm complexes with different substances.* Free hæm and hæmatin combine with imidazoles to form compounds which are very similar in their structure and absorption spectra to the hæmochromogens and parahæmatins formed when hæm or hæmatin are combined with a great variety of nitrogenous substances such as pyridine, nicotine, piperidine, ammonia, glycine or denatured proteins. In all these compounds, the fifth and sixth co-ordination valencies of the hæm–iron are occupied by molecules of the corresponding nitrogenous substances[23]. Were the fifth and sixth valencies of iron in hæmoglobin and methæmoglobin occupied by the imidazole rings of histidine residues, their absorption spectra would be expected to resemble those of a hæmochromogen or a parahæmatin, which is not the case.

(5) *Magnetic properties of hæmoglobin and its derivatives.* The magnetic properties of hæmoglobin studied by Pauling and his co-workers enabled them to determine for the first time the nature of the bonds uniting the iron with the surrounding atoms in hæmoglobin and its derivatives. One of the interesting results obtained by Pauling and Coryell[24] is that oxygen which is paramagnetic with two unpaired electrons per molecule, on combining with hæmoglobin which is also paramagnetic with four unpaired electrons per hæm, forms diamagnetic oxyhæmoglobin which has zero magnetic moment. This implies that both oxygen and hæmoglobin on combining to form oxyhæmoglobin or on dissociating from the latter undergo profound changes in their electronic structure. Such behaviour of oxygen during its reaction with hæmoglobin closely resembles its behaviour when submitted to pressure[25,26]. It was shown a long time ago, although the facts have not since become widely known, that when molecular oxygen is compressed, two molecules of oxygen combine reversibly according to the equation: $2O_2 \rightleftharpoons O_4$; the amount of $O_4$ being proportional to the square of the pressure. The formation of $O_4$ can be followed by magnetic measurement, since $O_2$ is paramagnetic and has two unpaired electrons, whereas $O_4$ is diamagnetic and has no unpaired electrons. Here again the formation of $O_4$ and its dissociation to $O_2$ are accompanied by a very marked rearrangement in the electronic structure of the molecule. It is interesting to note that the formation of $O_4$ can also be followed spectroscopically, since $O_4$ shows sharp absorption bands not only in the ultra-violet but also in the visible region of the spectrum, and these can easily be observed in a steel tube fitted with glass windows designed to withstand high pressures. With an optical depth between the windows of about 60 cm. and a pressure of 120 atmospheres (the usual pressure of an oxygen gas cylinder) the four absorption bands in the visible region can easily be seen with a hand spectroscope. Moreover, it is $O_4$ that is responsible for the blue colour and the very sharp absorption bands at 631, 577, 532 and 478 mμ of liquid oxygen when it is examined in a non-silvered Dewar flask by means of a hand spectroscope[25,26]. In fact, the diamagnetic $O_4$ represents about 50 per cent by weight of liquid oxygen.

Magnetic measurements, like other methods applied to the study of hæmoglobin, have great merits as well as limitations. There is no doubt that it is the only method which can reveal the character of the bonding of the iron with the surrounding atoms in hæmoglobin as well as in its reversible and irreversible derivatives. On the other hand, all this knowledge has not so far helped much towards an understanding of the fundamental properties of hæmoglobin, such as the very slow autoxidizability of its iron, its remarkable property of oxygenation, the peculiarities of the oxygen equilibrium curves, the Bohr effect, the nature of the hæm-binding protein groups, the position of the hæm in hæmoglobin, and many other properties, depending upon the integrity of the hæmoprotein molecule. Thus, for example, the Bohr effect cannot be ascribed[9,14], as was previously suggested[16], to changes in the nature of the bonds uniting the iron with the surrounding atoms from ionic of hæmoglobin to covalent of oxyhæmoglobin. In fact, the same changes in the nature of bonds take place in every hæmoprotein which can undergo oxygenation, yet myoglobin and certain hæmoglobins show no Bohr effect. On the other hand, the oxidation of hæmoglobin to methæmoglobin, which like oxygenation to oxyhæmoglobin shows a distinct Bohr effect, is not accompanied by changes in the nature of the iron bonding, which remains ionic.

Moreover, magnetic measurements do not differentiate between free hæm and hæmoglobin, each having four unpaired electrons, which indicates that the iron in both compounds is linked by ionic bonds. Neither do these measurements differentiate between oxyhæmoglobin and hæmochromogen which have no unpaired electrons, thus showing that the iron in both compounds is linked by covalent bonds. In other words, magnetic measurements do not reflect the remarkable differences between native hæmoglobin and those of its derivatives which have irreversibly lost their fundamental biological properties. The same limitation arises when the magnetic technique is applied to the study of other biologically active hæmoprotein compounds[27]. In this respect the study of magnetic properties of hæmoproteins fails to provide some of the information which is easily obtained from the biological and spectroscopic study of these compounds. In fact, by their absorption spectra, especially in the visible region of the spectrum, not only can all the derivatives of hæmoproteins be differentiated and identified but, in addition, any loss in specific biological activity can easily be recognized and estimated.

It appears that the results obtained from magnetic susceptibility measurements, which made possible the identification of the nature of the bonds uniting the iron with surrounding atoms, will not be made full use of until the structure of native globin, especially in relation to its biological specificity, is better understood.

(6) *Reconstruction of hæmoglobin from hæm and native globin.* The concept of the embedded hæms in hæmoglobin is difficult to reconcile with the comparative ease of its splitting into native globin and hæm and the reconstruction from these constituents of hæmoglobin which is capable of combining reversibly with molecular oxygen[28,29].

It is true that, under certain conditions such as those required for removal of hæms[30,31], treatment with strong urea solution[32-34], or high dilution[36,37], the hæmoglobin molecule or the liberated globin[36,31] may undergo a reversible dissociation into two equal parts. This phenomenon suggests that were the hæms embedded between layers of globin, their most likely position would be between the two halves of globin. However, the reversible dissociation of hæmoglobin into two halves is by no means a general phenomenon. It was recorded for hæmoglobins of horse, ox, cat and fœtal sheep, but so far has not been demonstrated for hæmoglobins of man, dog or adult sheep. Moreover, hæmoglobin reconstructed from free native globin and hæm differs from the original material in showing no Bohr effect and in having its oxygen equilibrium represented by a rectangular hyperbola[8]. The concept of steric hindrance cannot therefore be applied to the reaction of this hæmoglobin with oxygen even if the hæms in the reconstructed hæmoglobin are enfolded between the two halves of globin. On the other hand, hæmoglobins dissociated on dilution[36] or on treatment with urea[8] have an increased affinity for oxygen and retain the *S*-shaped oxygen equilibrium curve, although each half of the hæmoglobin molecule must be linked with two hæms now lying on the surface of the globin and therefore freely accessible to oxygen.

(7) *Hæmoglobin and myoglobin.* The view of the embedded position of hæms in hæmoglobin has not so far been extended to myoglobin. This is not surprising considering (*a*) that the size of the myoglobin molecule is only one-fourth that of mammalian blood hæmoglobin, (*b*) that the molecule does not undergo reversible dissociation into smaller units, and (*c*) that in the absence of a Bohr effect it is unnecessary to postulate the co-ordination of its iron with two imidazole groups of histidine one on each side of the disk-like hæm. On the other hand, if it is assumed that the four hæms of hæmoglobin are embedded between the layers of globin while the single hæm of myoglobin lies on the surface of the globin, the differences in the properties of these two pigments, especially the accessibilities of their iron to different reagents, would be greater than they really are. Myoglobin would also offer a more appropriate control than free hæm in the experiments with alkyl isocyanides carried out by St. George and Pauling[18]. That this is not the case is indicated by the reactions of methæmoglobin and metmyoglobin with different substances containing an imidazole group. Whereas both methæmoglobin and metmyoglobin combine reversibly with imidazole and 4(5)methyl imidazole, neither of these two pigments will react with histidine, histamine, carnosine, N-methyl benzimidazole or pilocarpine, which combine with the free hæm and hæmatin to form the corresponding hæmochromogen and parahæmatin compounds[38,39].

So far, all substances which are known to react with myoglobin and its reversible derivatives have been found also to react in the same way with hæmoglobin and its corresponding derivatives.

(8) *Evidence that the sixth co-ordination position around the iron in hæmoglobin and methæmoglobin is occupied by a molecule of water.* On drying hæmoglobin or methæmoglobin, their absorption spectra are replaced by those of hæmochromogen or parahæmatin respectively. On the reintroduction of water, these absorption spectra revert to their original states. Since in typical hæmochromogen and parahæmatin compounds both the fifth and the sixth covalent bonds of iron unite it to nitrogenous groups, the above experiments indicate that the sixth position around the iron in hæmoglobin and methæmoglobin is occupied by a molecule of water which, on drying, is replaced by a nitrogenous group of the protein[40-43].

This view is also supported by study of the absorption spectra of acid and alkaline methæmoglobin at low temperatures[44]. Thus, when a brown solution of acid methæmoglobin at *p*H 6 is cooled in liquid air, its absorption band in the red is intensified and slightly shifted towards the blue end of the spectrum.

On the other hand, when the red solution of alkaline methæmoglobin at pH 9, with absorption bands in the green, is cooled, it turns brown and its absorption spectrum changes to that of the acid form. Since cooling suppresses ionization[44], the above experiments indicate that the iron in acid methæmoglobin is linked to a molecule of water and that the formation of alkaline methæmoglobin involves the loss of a proton, as was originally suggested by Coryell, Stitt and Pauling[45], instead of the addition of a hydroxyl ion.

## Position of the Four Hæms in Relation to Globin

As is shown above, study of the structure and properties of hæmoglobin and its derivatives supports neither the theory of the embedded position of hæms within the fold of the globin nor the steric hindrance theory of hæm–hæm interaction. On the contrary, much of the evidence suggests that the hæms are attached to the surface of the globin through linkages with both the iron and the porphyrin. Of the six co-ordination bonds of the iron atom, four lie in one plane and link it with the nitrogen atoms of the pyrrol nuclei, whereas the fifth and the sixth bonds, one on each side of the disk-like hæm, unite it to a nitrogenous group of the globin and to a molecule of water respectively. This molecule of water can be replaced (1) in hæmoglobin by a molecule of oxygen, carbon monoxide, nitric oxide, hydrogen cyanide, an alkyl isocyanide or nitrosobenzene, and (2) in methæmoglobin by a hydroxyl, cyanide, hydrosulphide, azide or fluoride ion, nitric oxide, hydrogen peroxide, an alkyl peroxide or an imidazole, to give rise to the well-defined derivatives of hæmoglobin and methæmoglobin.

## Interaction between Hæms and Proteins in Hæmoproteins

Although the general weight of evidence invalidates the view that hæms in hæmoglobin are embedded between the layers of globin and that the hæm–iron is linked to the imidazole groups of two histidine residues lying one on either side of the flat hæm molecule, it does not dismiss the possibility that the imidazole rings may form the oxylabile groups responsible for the Bohr effect. Whatever may be the nature of these groups or their position, even if they are not directly linked with the hæm–iron, they may nevertheless be sufficiently influenced by the state of the hæm–iron to acquire the properties ascribed to the oxylabile groups. This is in general agreement with the view put forward by Wyman[46], namely, that the reactions of hæmoglobin with oxygen and carbon monoxide, as well as the Bohr effect, are intimately connected with marked changes in the structural configuration of the hæmoglobin molecule as a whole. In fact, the valency of the iron or its combination with different substances has a very profound effect upon the general protein properties of hæmoglobin such as solubility, crystalline structure, ease of crystallization and susceptibility to denaturation by different agents.

The converse is also true, namely, that the protein has a profound effect upon the properties of hæms linked to it. This is strikingly exemplified by many varieties of hæmoglobins which show marked differences in terms of affinities for oxygen and carbon monoxide, the shapes of the oxygen dissociation curves, the autoxidizability of the hæm–iron and the absorption spectra, especially in the visible region. That certain protein groups of globin which are not linked with, or are not even in close proximity to, the hæm may nevertheless affect its properties is clearly shown by the presence of the protein absorption band in the photodissociation spectrum of the carbon monoxide compound of myoglobin as demonstrated by Bücher and Kaspers[47]. Here the light energy absorbed at about 280 mμ by the two tyrosine and two tryptophane residues of globin is transmitted to, and used for, the photodissociation of the carbon monoxide–iron linkage.

That the protein portion of a molecule of a hæmoprotein cannot be considered as a colloidal carrier of hæmatin which merely enhances the activity of this prosthetic group is clearly illustrated by the fact that the same protohæmatin nucleus in combination with different native proteins may form highly specific hæmoprotein compounds such as hæmoglobin, catalase, peroxidase or a component of cytochrome which have several properties in common, but which show very striking differences both in the nature and in the magnitude of their biological activities.

## Effect of Magnet Inhomogeneities in the Strong-Focusing Synchrotron

The amplitude of transverse oscillations in a synchrotron due to gas scattering and spread at injection can be much reduced by using the strong-focusing principle[1]. In such a machine the oscillation amplitude is reduced in comparison with a conventional machine by a factor of order $0{\cdot}4\sqrt{n}$, where $n$ is the field index $(-r_0/H_0 . dH/dr)$. Oscillations induced by magnet misalignments are, however, larger in the strong-focusing machine by a factor of order $2\sqrt{n}$. This suggests that very accurate magnet assembly will be required.

As an example of the tolerances required, we first consider the effects of small random displacements of the sectors. The machine parameters used will be those of ref. 1, namely, $n \approx 3{,}600$; $N$, 240 sectors; orbit radius, $10^4$ cm.; $W$, half-width of vacuum chamber, 1 in. Suppose now that one of the sectors is displaced radially or vertically by $\delta$, then a simple calculation shows that an oscillation of order $5\delta$ will be set up. If all the sectors are displaced by an amount the root mean square value of which around the orbit is $\Delta$, the oscillation amplitude after one revolution will be of order $5\sqrt{240}\Delta \approx 75\Delta$. To ensure that the particle completes one revolution, therefore, we must have $75\Delta < 1$ in., that is, $\Delta < 0{\cdot}013$ in. This represents a fraction of $3{\cdot}6 \times 10^{-6}$ of the machine radius.

If this condition is met, it is important to inquire what happens on subsequent revolutions. A linear system will first be considered. This implies that $n$ is independent of radius, and the various small centrifugal terms in the equations of motion are neglected. We continue to assume for the moment that alternate sectors are identical in form. The behaviour on subsequent revolutions depends essentially on the change of phase of the oscillation after one revolution. Subtracting integral multiples of $2\pi$ from this phase change, so that the remainder $\varphi$ lies between $-\pi$ and $+\pi$, the oscillation amplitude fluctuates sinusoidally with an amplitude of about $2A/\varphi$ and a period of $\pi/\varphi$, where $A$ is the oscillation amplitude after one revolution. If $\varphi = 0$ the system is resonant, and the oscillation amplitude builds up linearly by an amount $A$ per revolution. In the general linear case where $n$ varies slightly from one sector to the next, a further type of resonance can occur. We consider first the special case of a correctly aligned machine. Particles displaced from the equilibrium orbit will oscillate with an amplitude which increases in a roughly exponential manner if $\varphi$ lies in a small region near 0, as in the resonances already considered, or near $\pi$ (cf. Mathieu's equation). In the general case of a misaligned machine with $n$-variation, or other perturbations proportional to displacement or velocity, both linear and exponential types of resonance will occur. For the machine under consideration a change of $n$ by 1·4 per cent varies $\varphi$ by $\pi$, so that it must be controlled throughout the accelerating cycle to less than this if disaster is to be avoided.

The resonant build-up of oscillation can be limited by making the system non-linear, so that $\varphi(A)$ is now a function of amplitude. To study this amplitude limitation, two series of computations are being made on the Automatic Computing Engine at the National Physical Laboratory. The first of these is a study of the pendulum equation $\ddot{y} + (n/4) \sin y = 0$, with a constant impulse forcing term at fixed intervals corresponding to one revolution in the machine. The oscillation has been computed for various values of $n$, $\varphi(0)$ and impulse strength. For the second more realistic calculations, the equation $\ddot{y} \pm n \sin y = 0$ is used, the sign alternating between focusing and defocusing sectors. At the amplitudes considered, only the $y$ and $y^3$ terms in the expansion of $\sin y$ are significant. The sectors are assumed to lie not on a perfect circle, but with their ends randomly distributed a certain distance from that circle, so that the computational problem is one of changing the $y = 0$ axis at each sector boundary. Particle orbits were calculated for one revolution through twenty-five randomly chosen arrangements of sectors to find the magnitude and variation in the amplitude due to misalignments, and for one typical arrangement the particle orbit was computed for up to sixty revolutions for various values of alignment accuracy.

The first calculation showed that $A'$, where $\varphi(A') = \pi + \varphi(0)$, is an important parameter. For small impulses the system behaves like a linear system when $\varphi$ is not near zero, and when $\varphi$ is near zero the amplitude of oscillation varies periodically and is limited to about $A'$. For impulses such that after one revolution $A$ is greater than about $A'/5$, the amplitude builds up erratically but indefinitely.

In the second series of computations the oscillation amplitude after one revolution was consistent with the simple statistical calculation given earlier. After many revolutions the behaviour was similar to that in the first series of computations, except that in the bounded solutions the repeating nature of the pattern of amplitude was not so clearly marked. Indeed, it is not certain that some of the apparently bounded solutions would not have diverged had the computation been carried over a larger number of revolutions. However, the limit of stability appeared to correspond to holding the sector tolerances to about $\pm 0{\cdot}007$ in. when the amount of non-linearity was adjusted so that $A' = W$.

We may conclude from these considerations that very great care must be paid to the magnet design in a strong focusing synchrotron. Elaborate methods of assembly will be necessary to get the particles once round the machine, and a very careful control of the field is essential to ensure that they do not hit the walls on later revolutions. Calculations so far suggest that, in principle, either a linear or non-linear system could be used, provided that the technological problems of constructing a sufficiently accurate magnet can be overcome. It must be emphasized, however, that there are many possible effects which we have not yet considered; notable among them are the coupling between vertical and horizontal oscillations, and the effect of non-linear inhomogeneities due to magnet profile inaccuracies and fringing fields.

We wish to thank Messrs. Bell, Goward and Walkinshaw for helpful discussions on the subject of this letter, and the Director of the National Physical Laboratory and members of the Mathematical Division for carrying out the computing programme. This work has been done in collaboration with the Proton Synchrotron Group of the European Council for Nuclear Research, and is published by permission of the Director of the Atomic Energy Research Establishment.

*Note added in proof.* An extension of the first series of computations to the case where *n* varies slowly from one resonant value to the next while an orbit is being computed shows that the oscillation amplitude can become very large, even though for *fixed n* values in the same range it remains quite limited. Such a variation of *n* is likely to occur during saturation of the magnet iron.

## Beta-Spectrum of Arsenic-71

For the past few months, the 225-cm. cyclotron[1] and the electromagnetic isotope separator[2] of this Institute have been used as the basic tools for a series of investigations on radioactive isotopes. Radioactive samples produced by cyclotron bombardment have been separated in the isotope separator both for obtaining mass assignments and for providing sources for beta-spectroscopic work. Due to the high intensity and high energy of the beam available in this cyclotron (200–300 μamp. internal beam of 25-MeV. deuterons), very intense beta-sources of separated isotopes can be obtained. The present communication reports the preliminary results of such an investigation on arsenic-71. The work is still in progress and a more detailed paper will be published later.

Arsenic-71 of half-life 60 hr. is obtained among several other arsenic activities by bombarding germanium with deuterons. The isotope is reported to decay by positron emission (energy 0·8 MeV., absorption measurements) and *K*-capture[3]. Mei *et al.*[4] reported an electron line of energy 162 keV., which was ascribed to arsenic-71.

In the present investigation, arsenic-71 has been studied in the intermediate image beta-spectrometer[5]. Germanium metal (fused on to a copper plate by using a special soldering flux) was bombarded in the cyclotron with 25-MeV. deuterons (180 μamp.hr.). The active arsenic, together with some arsenic carrier, was then converted into arsenic hydride. The hydride gas was introduced into the ion source of the isotope separator and the ions of mass number 71 were collected on a thin aluminium foil (0·15 mgm./cm.$^2$). This foil was used as a beta-source in the spectrometer (resolution about 4·5 per cent; the Geiger–Müller counter window had a 'cut-off' of about 6 keV.).

The Kurie plot of the positron spectrum obtained gives an upper limit of 815 ± 20 keV. There is also an indication of the presence of a weak component having the end point at about 300 keV. In addition to Auger lines, we have found three conversion electron lines at 12·2, 22·0 and 164 keV. The former two are interpreted as the *K* and *L* lines of a gamma-ray of energy 23·3 ± 0·3 keV. The 164-keV. line is interpreted as arising from the *K* and *L* conversion of a gamma-ray of energy 175 keV. This line is probably identical with the 162-keV. line reported by Mei *et al.*[4].

The positron continuum and the 164-keV. electron line appeared to decay with a period which was in accord with the half-life found for arsenic-71 (see below).

In another separation of arsenic from germanium bombarded with deuterons, we collected ions of all mass numbers from 69 to 77 on an aluminium foil, which was then cut into narrow strips. In order to check the half-lives, the decay of the activity corresponding to each mass number was followed for several days. The strip corresponding to mass number 69 showed a comparatively weak activity with a half-life of about 35 hr., indicating the presence of some germanium-69 in the arsenic hydride gas. The half-life of arsenic-71 was found to be 65 ± 5 hr.

We wish to thank Messrs. W. Forsling and L. Holm for their help and advice regarding the chemical work.

## Creep of Copper under Stress Pulses

A general treatment of the problem of creep under intermittent, as distinct from alternating, stress has already been given[1] and applied to the creep of lead. The behaviour of copper conductors is of particular interest[2] because of the stress conditions to which they are subjected in alternators, and because of the important consequences of their failure. Experiments on high-conductivity copper have now been completed with the view of testing in more detail certain deductions which followed from the original analysis.

The character of the creep of the copper wires when tested under 730 kgm.cm.$^{-2}$ at 258° C. depended strongly on the previous anneal time. The instantaneous extension increases, and the creep-rate at any chosen time decreases, with increase in the time of anneal. Detailed discussion of this is outside the scope of this communication: it must suffice to say that all the specimens were annealed in the furnace for 17 hr. prior to the creep test, a time sufficient for the effect to attain equilibrium.

The original analysis indicated that the recovery effect could be formulated in terms of one parameter, *n*. This was the fraction of the material which recovered in full, during the off-load period, its original transient flow properties. It was shown that for lead the flow exactly fitted the Andrade β, or cubic, function[3] $\beta t^{1/3}$, where $t$ is time.

The fraction *n* satisfied the relation

$$1/n = 1 + A(\tau/R)^{1/3}, \qquad (1)$$

where $\tau$ is time of load, $R$ the recovery time (restricted to values less than some critical value $R_c$) and $A$ a constant characteristic of the material. On this basis, approximations involving *n* can be developed for the case of regular repetitive stressing. In the case of copper under the test conditions quoted above, accurate cubic creep parabolas were again exhibited, with an instantaneous strain recovery on unloading

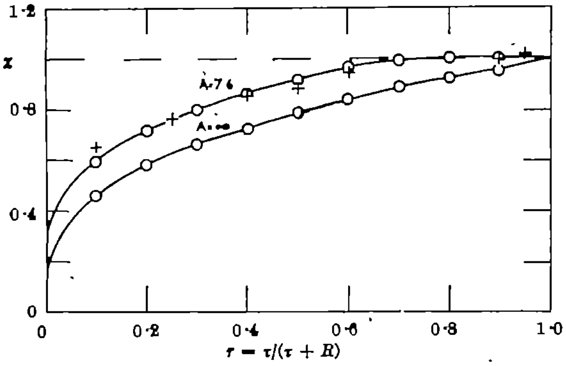

Fig. 1. Wave-form effect, showing the calculated values of χ (circles) for the two cases $A = \infty$ ('no effect') and $A = 7·6$. The crosses are the experimental observations

of ∼0·35 mm. followed by a negligible creep recovery. No modification to the previous treatment was found to be necessary to take account of this property.

It can be shown that the ratio of the creep strain under a regular intermittent stress system to that achieved under an equal continuous stress, and for the same total test time, is given by:

$$\chi = [2{\cdot}845n(1 - 1/m^{1/3}) + 1]\, r^{1/3} \qquad (2)$$

if the transient creep function is a cubic one, $m$ being the number of stress cycles and $r$ the ratio $\tau/(\tau + R)$. Two effects are of importance.

(*a*) *Wave-form effect*. The results of experiments made with $m = 8$, over a total test time of 80 min., are summarized in Fig. 1. The lower curve shows the χ-ratio for a material which exhibits no recovery ($A = \infty$), and the upper curve shows the ratio for the case where $A = 7·6$, the value deduced by fitting any section of one of the composite experimental curves. This calculated curve agrees very well with the experimental values obtained. It is worthy of note that χ can just exceed unity for this case ($m = 8$), and if a similar curve is calculated for $m = \infty$, then χ is found to exceed 1 over the large range of $r$-values, 0·3–1·0.

(*b*) *Frequency effect*. If $R < R_0$, equation (1) applies and $n$ is dependent on the $\tau/(\tau + R)$ ratio only and not on the absolute values of these quantities. In this sense, then, there is no frequency effect, so long as the wave-form is unchanged. However, because of the occurrence of the term $(1 - 1/m^{1/3})$ in equation (2), an effect arises when $m^{1/3}$ is small. As $m^{1/3}$ increases to values much greater than unity, χ levels out sharply to an asymptote at $\chi = (2{\cdot}845n + 1)r^{1/3}$. This is demonstrated by the calculated curve in Fig. 2 for the case where $A = 7·6$ and $r = 0·5$. The experimental points, taken from results after 80 min. of test at different frequencies, are again in very good agreement and confirm the validity of the general treatment and the physical concepts on which this is based.

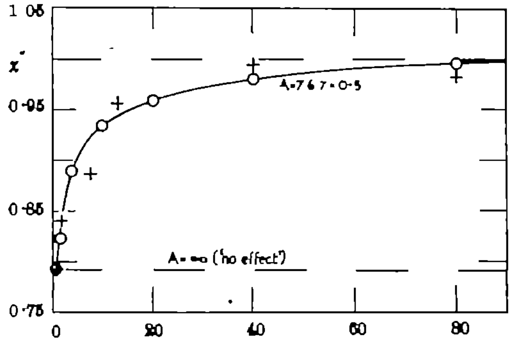

Fig. 2. Frequency effect, showing the calculated values of χ (circles) for the case where $A = 7·6$ and $r = 0·5$. The crosses are the experimental observations. If $A$ equalled ∞ ('no effect'), the points would lie on the horizontal line $\chi = 0·792$

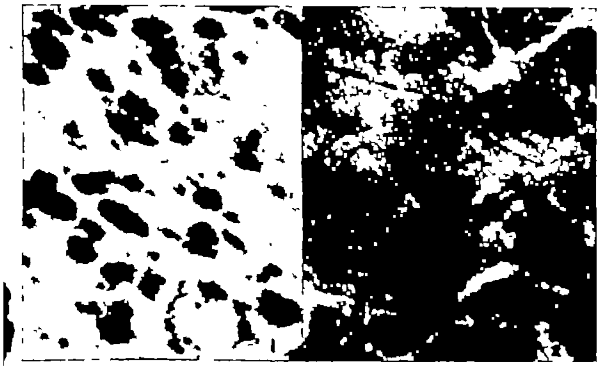
## Microscopical Identification of the Constituents of Coal Dust

In connexion with the work of the Pneumoconiosis Research Unit into the cause of pneumoconiosis, attention has been devoted to the problem of identifying and estimating the quantity of respirable constituents of the dusts found dispersed in the air in collieries. It was considered that a technique based on the plastic behaviour of fine particles as observed by me[1] and later confirmed by Bangham and Berkowitz[2] might be evolved.

A number of different types of crushing lenses have been made, and with them it is possible to crush suitably prepared samples of colliery dusts while watching them under the microscope. Coal substance under the conditions used becomes plastic and spreads. Minerals either spread, or shatter to smaller fragments, of micron size or less. They are colourless and thus easily distinguishable from the coal. Most coals in thin sections are highly coloured and the various ingredients readily recognized, the exceptions being those of high-rank, such as anthracites, which are practically opaque even in the thinnest sections.

The crushing technique for the estimation of some of the ingredients forming coal has now been improved so as to include the high-rank anthracites. The accompanying photographs (× 150) show two high-rank anthracites during crushing. Fig. 1 depicts particulate coal. The oval dark patches of the photograph are translucent and appear reddish-brown under the microscope; they are vitrinite. The lighter grey oval patches are exinite and are bright yellow under the microscope. (The correspondence between colour and constituent has been established in lower-rank coals and it seems reasonable to apply it to higher-rank coals.) The large rather irregular oval white patch is mineral matter. Fig. 2 is an almost continuous sheet of another anthracite formed by the coalescence of a deposit of fine particles in which irregular light-grey flecks (arrowed) represent the yellow exinite. Most of the photograph shows shades of darker grey which represent the vitrinite ingredients and is reddish-brown under the microscope. The clear patches in both photographs are uninterrupted light.

There is a striking difference in the amount of exinite portion of these two anthracites. It is interesting to see that the 'flash' of the yellow exinite as a contrast to the reddish-brown of the vitrinite is as apparent in the anthracite as in the lower-rank coals, although the carbon content is so much higher. It is hoped to investigate whether this phenomenon occurs in anthracites formed by the influence of heat.



Because of the persistence of different colours of the coal ingredients in the anthracites when treated this way, a quantitative estimation of the vitrinite, fusinite, exinite fraction of the coal of all colliery dusts should now be possible. The mineral fraction is readily estimated by the areas of translucency, and it is hoped, at least, to separate the minerals into several groups by a further development of the method based on interference phenomena.

## Alleged Optical Activity in Crystal Class *m*

Optical activity is theoretically possible in crystals belonging to the non-enantiomorphous classes *m*, *mm*2, $\bar{4}$ and $\bar{4}2m$; but only one substance has ever been cited as an example[1]. This is the dimer of the β-form of methyl mesityl oxide oxalate $(C_9H_{12}O_4)_2$, which was assigned by Sommerfeldt[2] to class *m* on the basis of morphological measurements.

Crystals corresponding exactly with those described by Sommerfeldt have been examined with X-rays and found to have the uniquely identifiable space group $P2_1/c$ with $a = 9{\cdot}15 \pm 3$ A., $b = 11{\cdot}56 \pm 5$ A., $c = 18{\cdot}02 \pm 5$ A., $\beta = 96° 12' \pm 20'$; $d_{\text{obs.}} = 1{\cdot}290$ gm.cm.$^{-3}$, $d_{\text{calc.}} = 1{\cdot}289 \pm 10$ gm.cm.$^{-3}$ for four molecules per unit cell. Sommerfeldt's axes are related to these by the transformation $102/010/\bar{1}02$. Polysynthetic twinning is prevalent, though the polarizing microscope gives no hint of this: the twins have $(10\bar{2})$ and [010] in common and the twinned reciprocal lattice approximates closely to Laue symmetry *mmm*. The habit of the single crystals resembles that of the crystals of the corresponding ethyl ester, which Sommerfeldt assigned to class 2/*m*. (The lattice of the ethyl ester apparently does not so easily permit analogous polysynthetic twinning.) The assignment of the methyl ester to class *m* is therefore erroneous though perhaps understandable.

Sommerfeldt's evidence for optical activity, which was only qualitative, may now be rejected for two reasons: (*a*) the centrosymmetry of the space group; and (*b*) his observations could, as Voigt[3] pointed out, be the result of twinning, or merely a consequence of increasing the illumination and so forcing a perceptible amount of light through the crossed nicols. This example may therefore be rejected, as it neither exhibits optical activity nor is in class *m*.

The absence of any example of optical activity in classes *m*, *mm*2, $\bar{4}$ and $\bar{4}2m$ may suggest some development of the existing theory or, more probably, reflects the considerable experimental difficulties of measuring optical activity in the presence of birefringence, and the decline of interest in this subject during recent years. A large number of substances have by now been reliably assigned to these classes, so that an intensive search among suitable representatives seems desirable.

A full account of the crystallography of the monomeric and dimeric forms, and a detailed discussion of Sommerfeldt's interpretation of the optical observations, will be published elsewhere.

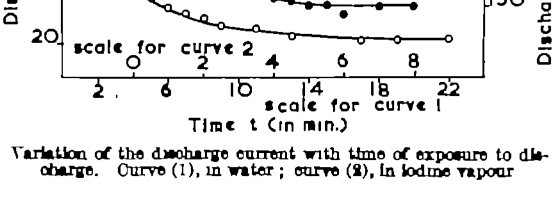
## Langmuir Adsorption as a Determinant of Conductivity in a Low-frequency Electric Discharge

The marked influence of sorption of electronegative gases on photo- and thermo-electric currents in a number of systems is well known[1]. We have now investigated the significance of Langmuir adsorption or chemi-sorption, chiefly occurring under discharge[2], in determining the conductivity of a gas excited at reduced pressures by low-frequency potentials.

Siemens-type ozonizers made of soft soda glass and degassed for the removal of pre-adsorbed gases by heating for 15 hr. at 200° C.[3] were employed; they were filled with iodine or water vapour at a desired pressure and excited by a 50-cycle potential. The root-mean-square value of the current *i* was measured by a microammeter or a galvanometer actuated by a crystal detector, vacuo-junction, etc.; and the nature of the current was studied by a cathode-ray oscillograph. The accompanying graph gives a typical series of results.

With the time of exposure to discharge due to a fixed applied potential sufficient to cause a self-



Variation of the discharge current with time of exposure to discharge. Curve (1), in water; curve (2), in iodine vapour maintained discharge, $i$ (and the associated high-frequency pulses observed on the cathode-ray tube) decreased rapidly and attained saturation within an appreciably short time interval (curves 1 and 2). It is suggested that sorption under discharge was exceedingly rapid[3], and it was attributed to the increased proportion, and accessibility to the surface containing free Langmuir sites[4], of gas particles with enhanced 'activation' energy[5]. Bangham[6] suggested that the amount ($x$) of gas adsorbed up to time $t$ follows a power–time law, $x = kt^{1/m}$. Our results also showed that the decrease ($\delta i$) in the conductivity up to time $t$ obeys a similar relationship (cf. curves 1 and 2 of inset graph: log $\delta i$ is sensibly a linear function of log $t$ as required by an equation $\delta i = k't^{1/m}$ analogous to Bangham's equation.

Calculations showed that the decrease of pressure due to uptake of gas particles by the known available surface area was inappreciable (for example, less than 0·01 mm. mercury when the initial pressure employed was 32·1 mm. of water vapour); in fact, theoretical considerations on the electrical discharge in gases[7] indicate that, for a fixed applied field, a reduction in gas pressure increases $i$, as actually observed[8]. The decrease of the conductivity (see graph) and its high-frequency pulses, with sorption on glass of iodine or water, are in agreement with the general decrease of photo- and thermo-electric currents by adsorbed electro-negative gases[1]; this suggests that atoms adsorbed on Langmuir sites increase the work function of the surface or inhibit the release from the (instantaneous) cathode of secondary electrons, the number of which controls the current $i$. If $S$ stands for a Langmuir site on clean glass surface, sorption of an electronegative atom such as iodine and its influence on electron liberation can be represented as:

$$S + I^{*} \rightarrow S - I;\ S - I + e \rightarrow S - I^{-}.$$

This indicates that atoms when adsorbed on glass retain their electronegativity; a view which is contrary to the current view that in Langmuir adsorption atoms adhere by sharing an electron with an alkali atom in the glass.

The work reported here was carried out in the Chemical Laboratories, Banaras Hindu University, Banaras.

## Determination of the Relative Electrode Potential of an Uncharged Metal in Solution

A RECTANGULAR frame pendulum (Herbert type), oscillating on a spherical glass bearing in contact with a metal surface and surrounded by an electrolytic solution, is known to exhibit a rate of damping which is roughly a parabolic function of the potential of the metal surface[1] (cf. the classical electrocapillary curve). Rehbinder[1] (see also Rozhanski[2]) envisaged the formation of "reversible micro-fissures" in the metal surface under deformation: the electrical double layer penetrated the orifice of the micro-fissure, reducing cohesion, and hence the hardness, of the metal.

Using a Herbert-type pendulum, a relation between $\frac{1}{a}\frac{da}{dt}$ (where $a$ is initial amplitude of oscillation of pendulum and $t$ is time) and potential was obtained on a zinc surface in $N$ hydrochloric acid with a maximum coinciding with that previously reported. The pendulum was then replaced by a 136° Diamond Pyramid (Vickers) hardness tester, employing a load of 1 kgm. (the same weight as the pendulum), and the same solution and potential variation conditions. No variation of hardness with potential was observed: Rehbinder's explanation hence appears invalid.

The maxima of the $\frac{1}{a}\frac{da}{dt}\Big/$potential relations were determined in $N/10$ and $N/100$ aqueous solutions of hydrochloric acid for zinc, lead, cadmium, copper and nickel. These 'decay maxima' lie upon the linear relation which exists between the potentials of the electrocapillary maxima[3–5] of mercury, gallium and platinum, and the work functions of these metals. Further, determination of the potential of the decay maxima on an amalgamated copper surface in (not highly purified) $M/10$ hydrochloric acid showed this to be $-0·19 \pm 0·03$ V. on the hydrogen scale, whereas in the absence of specific adsorption the potential of the electrocapillary maximum at a mercury-solution interface is about $-0·22$ V. (That the potential of the electrocapillary maximum on amalgamated copper can be taken as closely approximating to that on mercury under the same solution conditions follows, for example, from the equivalence of the overpotential[6] results on mercury and amalgamated copper at the same current densities.) These facts strongly suggest that the potential of the decay maximum can be identified with that of the electrocapillary maximum (charge-free surface). An experimentally easy method of determining the potential of a charge-free surface at a solid metal-solution interface is therefore available. Previous indication of this was by a comparison of pendulum maxima with electrocapillary maxima obtained by measurements on molten zinc in a eutectic of potassium and lithium chlorides[7]; but the invalidity of the conversion of potential scales from that used in the molten, to that of the aqueous, system makes this comparison useless.

It can be shown that $\frac{1}{a}\frac{da}{dt} \simeq K\mu$, where $K$ is a constant and $\mu$ is the coefficient of friction of glass or metal. An explanation of the phenomenon reported therefore rests upon understanding the dependence of friction on interfacial potential. An appreciable layer (continuous or broken by 'welds' between metal and bearing) of electrolytic solution must exist between the metal and the pendulum bearing. Except at the point of zero charge, excess ions of one sign exist in the double layer and mutually repel each other, thus resisting compression increasingly with increasing departure from the potential of zero charge. As the charge on the metal increases, the mean distance from the bearing surface to metal surface increases, thus reducing the attractive force between the surfaces (or, effectively, the load of one surface on the other), and so diminishing the friction. Hence, $\mu$ is greatest when zero charge exists on the metal surface, and the potential at this point thus coincides with the $\frac{1}{a}\frac{da}{dt}$-potential maximum.

It was suggested by Barker[8] that the chief features of the friction-potential relations of platinum are due to the adsorption of oxygen and hydrogen. Bowden and Young[9] later advanced a dual explanation in which effects due to the electrical double-layer are superimposed on effects due to adsorbed gases. That adsorbed gases are not always necessary to explain the effects of potential on friction is shown by the results for amalgamated copper where, for the potential range studied, adsorbed oxygen is absent and the adsorption of hydrogen is very small.

## Mechanism of Electropolishing

*Electropolishing in molten salts.* I have found that gold, platinum and palladium may be anodically polished using pure ('Analar') molten potassium chloride or sodium chloride as electrolyte. With palladium electrodes of about 1 cm.$^2$ area and 2 cm. apart at about 950° C., etching occurred at low current-density, but gave place to polishing at about 1 amp./cm.$^2$ (calculated on the inner faces only) and 3 volts potential difference. For gold at 970° C. and platinum at 1,020° C., using a 3-cm. diameter nickel crucible as cathode, there appeared to be no clearly defined lower limit to the polishing conditions, but polishing was observed at and above 0·15 amp./cm. and a potential difference of 1·5 volts. Palladium was also polished in an enclosed system with hydrogen bubbling vigorously through the electrolyte around the anode.

'Baser' metals than the three mentioned (for example, iron and copper) give less brilliant results, probably because they are attacked while cooling by the contents of the adhering electrolyte.

*Conditions at polishing and etching anodic surfaces.* The adsorptive conditions at polishing and etching copper surfaces have been directly compared in an arrangement consisting of a vertical cathode (1 cm. square) and a horizontal anode (1 cm. × 5 cm.) with its long axis normal to the cathode and its tip 1 cm. from the centre. In 50/50 v/v phosphoric acid, it was possible to adjust the voltage (*c.* 1·2 V.) so as to produce three differing anodic bands simultaneously: (*a*) polish for 1 cm. from the tip; (*b*) an intermediate area; (*c*) etch on the remainder. When about 1 per cent of 'saturated' mercuric nitrate solution was included in the electrolyte, amalgamation took place on all except the polishing surface (*a*). Similarly, on anodes which had narrow, lightly amalgamated lines drawn along their lengths, mercury was removed in the polishing region but the lines broadened in the etch region. Bands similar to (*a*), (*b*) and (*c*) were produced in an electrolyte of 1 *M* $CuSO_4$ (at *c.* 3 V.) and behaved correspondingly towards mercuric ions, although the area (*a*) was matt and after a few minutes became covered with a dark brown deposit. In both phosphoric acid and copper sulphate, mercury droplets sprayed over the anode would not adhere readily to the area (*a*).

The experiments in molten electrolytes show clearly that electropolishing cannot be explained by postulating layers of oxide, hydroxide, etc., on the anode[1], for in this case the substances corresponding to oxides would be chlorides of the metals concerned, and under the conditions of the experiments the lattices of the chlorides of gold, platinum and palladium could not exist. The possibility of oxide films due to dissolved oxygen is ruled out by the experiment in hydrogen and by the observation that in all cases polishing could be obtained at temperatures well above those at which oxide could survive. Similarly, it is concluded from the behaviour of copper anodes towards mercuric ions in aqueous solutions that the non-adherence of mercury droplets to a polishing surface, reported by Hoar and Farthing[2], is due not to oxide films but to failure to establish a contact-adsorbed film of mercury at the relatively high current-density required for polishing. Further, since the etch-forms and growth-forms of metal crystals are controlled by adsorption[3], the observations indicate that at high current-density etch is inhibited because the formation of regularly adsorbed layers is prevented. Polishing should then follow automatically, since the electric field will be highest at projections. The matt surface of type (*a*) obtained in copper sulphate electrolyte is believed to be due to the formation of solid by-products in contact with the metal, since it resembles that of a copper single crystal which has been attacked by iodine vapour with the formation of solid cuprous iodide.

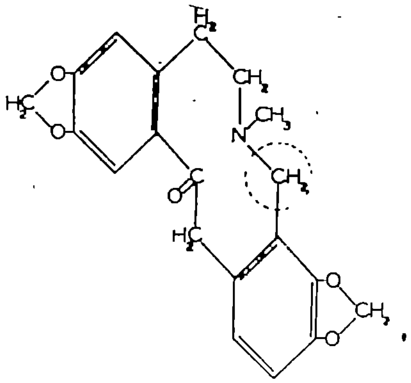
## Origin of the Methylenedioxy Groups of the Alkaloid Protopine

There is a rapidly increasing body of evidence in the literature that all biological methylation processes, as well as many other 'single-carbon' biological syntheses, have a common pattern. It has been shown that the N-methyl groups of the alkaloids



Protopine

hordenine[1,2] and nicotine[3], and the N- and O-methyl groups of the alkaloid ricinine[4], have the same origin as the labile methyl groups in animal metabolism. Similarly, the O-methyl groups of barley lignin have been shown to fit this same pattern[5]. We have recently extended these observations to the methylenedioxy and N-methyl groups of the alkaloid protopine.

The plants used in these experiments were *Dicentra* hybrids (*Dicentra eximia* (Ker.-Gawl.) Torr. × *Dicentra oregana* (Eastwood)), which we have shown produce considerable amounts of protopine under the conditions of these experiments. Three rapidly growing young hybrids were fed, respectively, carbon-14 methyl-labelled L-methionine, carbon-14 methyl-labelled choline and carbon-14-labelled sodium formate. The labelled materials were administered dissolved in the liquid culture solution[6] in which the plants were growing. At the end of a one-week growth period in contact with the labelled materials, all three plants had translocated activity to their topmost leaves and were removed from the solutions and dried in an oven at 110°. The dried plants were extracted with methanol in a Soxhlet extractor, and carrier protopine (500 mgm. per plant) was added to each extract. The protopine from each extract was isolated according to the procedure of Manske[7] and purified to constant specific activity by recrystallization of the free base and its nitrate salt from methanol. The specific activity of the N-methyl group was determined by degrading a portion of the alkaloid according to the methylimino determination of Pregl[8] and trapping the liberated methyl iodide in trimethyl amine. The tetramethylammonium ion was counted as its reineckate. The specific activity of the methylenedioxy groups was obtained by the hydrolysis of a separate portion of the alkaloid with 20 per cent sulphuric acid followed by the isolation and counting of the liberated formaldehyde as its dimedone derivative. The results of these determinations are shown in the accompanying table.

| Metabolite administered | | | Specific activity (c.p.m. per m*M*.) | | |
|---|---|---|---|---|---|
| | Weight (mgm.) | Activity (c.p.m.) | Protopine | Methylenedioxy group | N-methyl group |
| L-Methionine | 82 | $1 \cdot 2 \times 10^7$ | $8 \cdot 8 \pm 0 \cdot 1 \times 10^5$ | $1 \cdot 5 \pm 0 \cdot 1 \times 10^5$ | $1 \cdot 9 \pm 0 \cdot 1 \times 10^5$ |
| Sodium formate | 10 | $5 \cdot 0 \times 10^7$ | $1 \cdot 3 \pm 0 \cdot 1 \times 10^5$ | | |
| Choline chloride | 60 | $3 \cdot 0 \times 10^7$ | 0 | | |
